CANADIAN MACHINERY
AND
MANUFACTURING NEWS

Volume XX. No. 1 July 4, 1918

THE first sheet mill in Canada to operate successfully was installed a few months ago by the Steel Company of Canada, Ltd., at its Hamilton, Ont., plant. This is one of the most important developments in the iron and steel industry in Canada that has taken place in some time, and one that has been even more successful than the management anticipated. Until quite recently all black sheets used in Canada were imported from Great Britain or the United States. It was evident that there was room in Canada for a sheet mill if operated under practical conditions.

A few years ago a sheet mill was installed at Morrisburg, Ont., but for many reasons the proposition was not a success, and the plant lay idle for some time. Last year the Steel Company of Canada, seeing an opportunity for developing its activities and increasing its already wide range of products, purchased the plant at Morrisburg, and installed it, together with important additions, at Hamilton. The entire plant was removed to Hamilton, including mill, furnaces, machinery, and buildings. The plant as reconstructed is one of the most modern and up-to-date sheet mills on this continent. The first sheet was rolled on January 16, 1918, and galvanized the same day by the Dominion Sheet Metal Co., of Hamilton.

*Associate Editor Canadian Machinery.

Historical Sketch of Sheet Industry

To digress, a brief history of the steel sheet industry will be interesting as it shows its importance which is growing every year. The demand for steel sheets has increased to such an extent that the supply for some time has been short of requirements. The necessity of sheet iron or steel for so many products, not until more recent years made from this material, is becoming more and more apparent. The growing demand is due largely to the growing scarcity of lumber and also because of the fire resisting qualities of steel sheets. The variety of purposes for which steel sheets are used are too numerous to mention, the building, galvanizing and automobile industries alone require a large tonnage every year. Mill construction and method of manufacture have changed considerably since the early days of the industry. Efficiency in operation and a superior product has resulted from the more modern conditions surrounding the manufacture of steel sheets.

In ancient days the production of thin sheets of iron was accomplished by a very laborious process. Pieces of wrought iron were heated in blacksmith fires and hammered flat and as thin as possible on an anvil. Then several pieces were piled on top of each other, reheated to a red heat, and again hammered until the several layers had reached the required thickness. Naturally sheets of small dimensions only could be produced in this manner. Later the crocodile or helve hammer, driven by water power, came to ease the hard manual labor of the smith.

The process of rolling sheets was invented in England in the eighteenth century. This was a marked step advance in that it not only produced sheets of more uniform thickness, more pliable and of larger dimensions, but also materially reduced the cost. In course of time many labor-saving devices in auxiliary machinery and for detail work were invented, but the fundamental principle in rolling has not been materially changed. American ingenuity, however, is still actively at work, and in the future highly improved rolling methods undoubtedly will be developed.

The invention of galvanizing, that is, the process of coating iron and steel with spelter, or zinc, for the protection of the material against corrosion, has broadened the field of usefulness of sheet iron and sheet steel enormously.

Previous to the last century, improvements in the methods of its manufacture progressed but slowly. Gradually, and from stage to stage, various modes came into use; principal of which were the Catalan forge, the bloomary or knobbling fire, the blast furnace, and the puddling furnace. It has remained, however, for modern times to make marked advances in the iron industry, and in the production of steel, chiefly by the blast furnace and the Bessemer and Siemens-Martin, or open hearth process. The results have been immense tonnages and the development of a colossal industry.

In the United States the rolling of iron sheets was first started early in the nineteenth century, the first American sheet rolling mill being built in Pittsburgh in 1818, one hundred years ago. It appears that a plant was established by the Pittsburgh Steam & Engine Co. In that year, according to James Swank's book, "Iron in All Ages," the mill was established under the superintendence of Joshua Malen of Valley Forge, a well known figure at that time in the iron and steel industry. The mill had two steam engines each of 120 h.p. An idea of the wonderful development of the sheet iron business can be obtained when it is noted that less than 100 years ago a rolling mill with 240 h.p. was considered a large plant, while now the Vandergrift plant, which is only one of two large groups owned by the company, is equipped with over 12,500 h.p.

On account of the close connection between the steel sheet and galvanizing industries a brief history of the galvanizing process will be of interest. The process of coating iron with tin was invented about 400 years ago in Saxony. The process was kept a secret by the Saxons for nearly 100 years, but after diligent search English manufacturers about the end of the 17th century learned the secret. In England where some time after this discovery the process of rolling sheets was invented, the tin plate industry grew rapidly and for nearly 200 years England maintained the supremacy in this industry. In recent years, however, the United States has become a strong rival and is now the largest tin plate manufacturing country in the world.

Tin plate was first made in the United States in 1872, but owing to the low duty on foreign tin plate, the manufacture of this material ceased in 1878. In 1890 the duty was increased by Congress and manufacturing was started again. Since that date the industry has developed in a remarkable degree in the United States. A few years ago a galvanizing plant was established in Hamilton by the Dominion Sheet Metal Co. and now the sheets are being rolled in Hamilton by the Steel Company of Canada, marking another stage in the industrial development of Canada. The next step will be the manufacture of tin plate and unless all indications prove erroneous, it will not be many years before tin plate is being made in this country.

Steel Company's Enterprise

The success which has attended the Steel Company's operations during the last three or four years has enabled the management to branch out into new fields of endeavor and continue the progressive policy which has always been associated with the concern's affairs. It will be understood that the financial outlay involved in the laying down of a sheet mill is considerable and can only be undertaken by a firm able to command the requisite capital. The Steel Company of Canada has during the past three or four years enjoyed a remarkable period of success and considerably augmented its financial resources. The large demand for its products during this period and business acumen of the management has placed the firm in an enviable position. It has also given the firm an opportunity to develop its business which will not only benefit the company but the country generally by reason of the large variety of home-made products available for other industries, keeping money in the country which otherwise would go abroad and also in the distribution of money in the form of wages. With the growing demand for

steel sheets in Canada the demand for the company's product will increase proportionately. An advantage which the Steel Company of Canada enjoys is that it makes the steel from which the sheets are rolled and can therefore produce steel of the correct analysis for the purpose for which it is required. The company is thus able to produce a high grade and even quality sheet with perfect assurance.

Other Plant Developments

In order to strengthen the company's position in regard to its supply of raw materials, a most important and necessary factor, the directors have acquired an interest in two valuable ore properties, one on the Mesaba Range and the other on the Gogebic Range. The proportion of the ore which the company is entitled to receive from these two properties will be sufficient to meet over half of its total ore requirements each year for a considerable number of years. The ore taken out each year is paid for on a royalty basis, so that beyond paying for its share of stripping and equipping the mines, no large expenditure of capital was necessary. During its season of 1918 the company will receive its quota of ore from the mine on the Gogebic Range and shipments from the Mesaba Range mine are expected to commence late in the season of 1918. Satisfactory arrangements have also been made recently for an ample supply of coal.

The company is constructing at Hamilton a large by-product coke oven plant which, it is expected, will be in operation by November. An ample supply of good quality coke will always be available for the blast furnaces, thus further relieving the company of anxiety in regard to supplies of raw materials. The by-products obtained from the ovens will make it a profitable undertaking.

Making Steel for Sheets

To impress upon the reader the advantages which the Steel Company of Canada possesses in manufacturing steel sheets, it will be in order to deal briefly with the manufacture of the steel from which the sheets are made. The company makes sheets straight from the pig iron to the finished product. It will thus be realized that the company was in a particularly favorable position to embark on the new enterprise. The plant is complete in every detail, and is generally conceded to be of most modern design and construction. A striking feature is the way in which "Safety First" mechanical appliances have been utilized to gain efficiency, save life and labor and keep down cost of production. Considering the size of the plant it is remarkable how few men are employed, although the pay roll of course is not by any means a small one. The physical condition of the plant is decidedly satisfactory and indicates the far-sighted policy of the management. Electric power is used wherever possible, a factor in the efficient operation of the plant.

Blast Furnace Plant

There are two blast furnaces, having a daily capacity of 400 and 300 tons respectively, one of these furnaces being devoted exclusively to the production of iron for the steel furnaces, while the other produces alternately malleable and foundry pig iron according to requirements of the market. The ore which comes in by boat is brown hematite, one of the richest forms, containing in some cases 68 per cent. of iron.

The blast furnace is charged at the top with ore, limestone and coke, which gradually descend and ultimately melt in the intense heat of about 3,000 degrees Fahr. The proportions of materials forming the charge are carefully regulated and vary according to the quality of steel required. The air for the blast is supplied at a pressure of from 15 to 30 lbs. per square inch, according to furnace conditions, the blowing engines being of the disconnected compound, long cross head, vertical type. The steam cylinders are 44 in. and 84 in. diameter by 60 in. stroke and are placed above the blowing cylinders.

Before entering the furnaces the air is heated to a temperature of from 900 to 1,250 degrees Fahr. by passing through the hot blast stoves. There are three stoves to each furnace, the stoves being 100 feet high by 20 feet in diameter, and heated by waste gases from the furnaces.

Refrigeration is used for drying the air blast before being heated in the stoves. Undried air if blown directly into the furnaces, would carry with it water vapor equivalent to from 1 1/3 to 8 gallons per minute, according to the humidity of the air, materially cooling the smelting zone of the furnace. The process of drying air by refrigeration was originated by James Gayley, a prominent American steel maker. The air-drying plant consists of three 150-ton compound steam-driven ammonia compressors, which supply the necessary refrigeration for cooling brine which is circulated by three steam-driven, fly-wheel type, brine pumps. The furnace is tapped about every six hours, the slag being drawn off through the cinder notch four or five times during this period. When the tap hole is opened, the hot molten metal flows in a channel to the end of the cast house into large ladles mounted on trucks, by which it is quickly transferred to the open hearth furnaces to be converted into steel.

MACHINERY ROLLS. ROLLS ARE LOWERED THROUGH THE TRAP IN ROOF OF MACHINE SHOP BY TRAVELLING CRANE DIRECTLY TO THE LATHE.

Open Hearth Steel Process

Black sheets are made of basic open hearth steel. The open hearth furnaces are always in operation except when repairs have to be made. The charging floor is at the back, and is on the same level as the furnace hearth, while the metal is drawn off on the opposite side. Two charging machines which travel along the entire length of the floor are used for feeding the furnaces with scrap steel and limestone. At the opposite side of the furnaces is the casting pit on the ground level, over which travels an electric crane for lifting the ladles and teeming the molten iron into the open hearth furnaces. This molten metal has been brought direct from the blast furnaces, thereby avoiding the necessity of charging the O. H. furnace with pig iron.

When the steel in the open hearth furnaces has been heated for a certain length of time, during which period other materials have been added to produce a steel of suitable physical properties for sheets, it is teemed into a ladle suspended from the overhead crane and poured into moulds of heavy cast iron construction, forming ingots. The filled ingot moulds are then hauled in a train of cars to the rolling mill, by which time the metal is sufficiently solidified to allow the mould to be drawn off or stripped. This is done by a 75-ton crane, which has a pair of links which grip the mould under the lugs and lift it up clear of the ingot. Another crane immediately grips the ingot and deposits it into a soaking pit, where it is maintained in an upright position at a steady temperature for about one hour.

The ingot is then lifted out of the soaking pit and deposited on an electrically operated truck and carried forward to the approach table of the blooming mill. The soaking pit furnaces are fired with producer gas and the soaking treatment is necessary to allow the ingot to attain an even temperature throughout and also to confine the pipe or segregation core to the centre. The ingot is 15 in. x 17 in. x 7 feet long.

Rolling Blooms for Sheet Bars

The blooming mill is very complete in design and construction and together with its power plant is one of the best on this continent. The installation consists of a two-high 34-inch reversing, motor-driven, Morgan blooming mill. The approach table is operated by a 30-horse power d. c. motor, while the tables on either side of the mill are driven by 100 h.p. motors. The side guards for handling the bloom from one part of the rolls to the other are operated by hydraulic gear. The entire operation of the mill is controlled from a platform or pulpit located above the table affording a clear view of the rolls and the work. The blooming mill is driven by a 3,000 h.p. twin armature reversing motor of special design for this particularly severe service. The ingot is passed back and forth between massive steel rollers, which, while reducing the cross-sectional area, increases its length until, when reduced to 6 inches square, the bloom as it is now termed is about 50 feet in length. After being reduced to the desired size, which is accomplished in 15 passes, the bloom is cut into suitable lengths in a 10 x 10 inch vertical bloom shear. The blooms then pass to the bar mill to be rolled into sheet bars.

The method of rolling sheet bars is very similar to that of rolling blooms as described above. The bloom, after passing through the sheet bar mill is increased in length to 30 feet and is 8 inches wide. The sheet bars are laid on a cooling table and afterwards carried over to the sheet mill.

The Product

Steel sheets vary in thickness from No. 30 to No. 12 gauge, in length from 5 feet to 12 feet, and in width from 24 inches to 40 inches. As a general rule sheets below No. 28 gauge in thickness are rolled on a tin mill and sheets over No. 16 gauge should be rolled on a jobbing plate mill. The Steel Company of Canada is rolling sheets from No. 14 to No. 30 gauge inclusive, being the extreme range for the mill consistent with efficiency and economy.

They are "one pass cold rolled and box annealed sheets" and are being used for a variety of purposes. A considerable tonnage is being used by the galvanizers as well as in the automobile trade. The output at present is about 1,500 tons per month but could be doubled if the required amount of steel was available. War conditions prevent capacity production being attained.

The company has not as yet undertaken the manufacture of tin plate although the process follows closely for a certain number of operations that of sheets, with the main exception that sheets are always rolled from heavier bars. In both cases the order of operations is in the same sequence, viz., shearing of the bars, heating of the bars and roughing the bars, at this stage called pairs. The doubling shear of the tin mill, however, is not used in a sheet mill and from this point the operations change. Sheets for galvanizing are cold rolled, close annealed and must pass physical tests required by the most rigid specifications. In fact all sheets are made to stand certain physical tests according to the purpose for which they are required.

Sequence of Operations

The sequence of operations in manufacturing sheets is briefly as follows: Shearing the sheet bars, heating the bars, roughing the bars, reheating the sheets, doubling the sheets, reheating the pack of sheets, finish hot rolling. The next operation is to shear the pack to the required size after which the pack is opened and the sheets separated. The sheets are then cold rolled, annealed, cooled, piled in the warehouse and prepared for shipping. In some cases the sheets are annealed before being cold rolled.

Layout of Plant

The plant is laid out in such a manner that the bars and then the sheets pass from one operation to another, beginning at one end of the mill and finishing at the opposite end. The only exception to this is when the cold rolling follows the annealing. The shears come first, then the furnaces, rolls, trimming shears, while further along are the annealing furnaces, cooling floors and lastly the warehouse and the shippin room.

The mill building is 700 feet long. The main bay is 60 feet wide, and the side bays 29 feet and 20 feet wide respectively. The building is of brick and steel construction with steel roof trusses and monitor roof. The building is lofty, the distance to the overhead crane tracks being 20 feet. A 20-ton Shaw electric traveling crane runs from end to end of the building. At one corner is located a machine shop in which is installed a lathe for turning rolls, and a grinding machine for sharpening the knives for the squaring shear. The pair furnaces are of the combination type for sheet mill work, while the mill train is situated near the furnaces, the motor for driving the mill train being in a separate room built in the main building.

The annealing furnaces at the other end of the building are located in one of the side bays and on the opposite bay is the warehouse. The warehouse is a brick building, steam heated, adjoining the mill building and is 25 feet wide by 100 feet long. The mill offices, lavatories, and shower baths are a continuation of the warehouse. In addition to the 120-inch squaring shear there is another 72-inch shear for smaller and miscellaneous sizes of sheets. Near the

SHEET ANNEALING FURNACES. SHEET BARS AND REAR VIEW OF FURNACES. COMBINATION SHEET AND PAIR FURNACES. WAREHOUSE SHOWING SHEETS BUNDLED FOR SHIPPING.

warehouse there is a small shear for cutting out test pieces, etc.

Shearing Sheet Bars

The bars from which the sheets are made come from the mill in 30-foot lengths, 8 inches wide. The thickness of each bar varies in accordance with the gauge of sheet into which it will be rolled. The sheet bars are piled in their respective thicknesses near the shears. The bars are lifted on to a table on the approach side of the shear and pushed through the gap of the shear until it touches the stop guide on the delivery side, this guide having been previously adjusted to the desired length of crop.

When an order goes through for rolling a certain size of sheet, the proper size sheet bars are sheared and the short pieces piled. The length of these short bars is predetermined by the size of sheet. Each bar is marked with the weight per foot and a number corresponding to the gauge. The sheared bars are now called pairs and are ready for the furnaces.

Combination Sheet and Pair Furnaces

The furnaces are known as combination sheet and pair furnaces, a type now used in modern sheet mill practice. The system consists of two furnaces one behind the other. with a single combustion chamber. The rear furnace is for the bars and the front nearest the mill is for the sheets. Between the combustion chamber and the pair furnace hearth is a bridge wall, and between the pair furnace hearth and the sheet furnace hearth is a second bridge wall. The products of combustion pass from the combustion chamber over the bridge wall to the hearth of the pair furnace, and, after heating the bars, pass over the second bridge wall and serve to heat the sheets in the sheet furnace. The combination furnaces are coal fired and maintained at a temperature ranging from 1,200 to 1,300 degrees Fahr. The bars are fed to the furnace by hand and the sheets or pairs are handled in the same manner.

Arrangement of Rolls

The mill train is two high and has six stands of rolls, four stands being for hot rolling and two stands for cold rolling. Of the hot rolls three stands only are at present in operation, one in the centre for roughing and one on each side for finishing. The breaking down or roughing rolls are 44 inch and the finishing rolls 36 inch. The two stands of cold rolls are 40 inch and 42 inch respectively. The mill train is driven by means of a 650 h.p. Westinghouse a. c. motor through rope drive, the fly-wheel being of large diameter and heavy. The rope drive is at the end of the mill train and provision has been made for installing another mill when necessary.

Rolling Sheets or Pairs

The bars having been sheared into suitable lengths are heated in the back end of the combination pair furnace. After they are heated to the required temperature they are taken out of the furnace by means of tongs, two at a time, the heater throwing them to the roller. The roller takes first one bar and then the other, passing them through the roughing or breaking down rolls two or three times to the catcher on the opposite side of the stand, who returns them over the top roll, using its direction of rotation to assist in this operation. After two or three passes in the finishing mill the roller places one of the bars on the top of the other and they are given as many passes as the heat will allow.

As the sheets cannot be rolled thin enough in two thicknesses except in the heavier gauges, they must now be doubled. This is accomplished by taking one end of the sheet and doubling it over another and taking it to the doubling machine. The doubling machine consists of a vertical plunger press which closes down the sheets, one on the other. When rolling the lighter gauges of sheets, the bars are put together in threes, fours or fives. After doubling, the result is a pack of four sheets but practically cold. The pack is now put into the front or sheet furnace and reheated. After being heated to the correct temperature the pack is again carried to the roller and repassed through the finishing rolls several times until the desired thinness is obtained. The roller knows when to stop rolling by gauging the length and width of the sheet. The pack does not weld together because the top friction roll runs slower than the positively-driven bottom roll. As in the case of the shearer, the roller receives instructions as to the size of sheets to be rolled on a certain rolling so that the various gauges will not get mixed up. The mill is in continuous operation, the crew of eleven men working right through for the eight hours' shift.

The pack of sheets, four or more in thickness, is now carried over to the squaring shear to be sheared to the size called for in the order. The squaring shear has a 120-inch knife. The pack is now opened that is separated into individual sheets. If the rolling has been done at a proper heat this is a matter of little difficulty, but occasionally they stick together and have to be separated by means of a blunt knife. After the pack has been opened the sheets are inspected. The sheets are then piled according to their respective gauges.

Cold Rolling Process

The usual practice at this mill is to give the sheets one pass in the cold rolls before annealing. Sometimes this operation is reversed. The process of cold rolling consists of passing the sheet through a pair of rolls exactly similar to the hot rolls, but without reheating the sheet. The cold rolling flattens out the sheet and removes burrs or fins on its edges caused by the shear knives. When the sheets are annealed before cold rolling, the rolling accomplishes the above and in addition closes the pores of the sheet, resulting from the annealing treatment. It also gives the sheet a clearer and brighter finish which is desirable for some classes of work. Sheets required for galvanizing are cold rolled before being annealed. Before being galvanized the sheets are pickled, a process which cleans the sheet and removes the scale, etc., thus a bright finish at the mill is unnecessary.

Annealing the Sheets

After the sheets have been rolled they are hard and must be annealed before they can be usd commercially. The sheets are taken from the piles near the mill, placed in bundles on a cradle and carried by the overhead travelling crane to the annealing furnaces at the other end of the mill building. Annealing is an important operation as the sheet must be sufficiently soft to stand working up.

At the present time there are three double annealing furnaces, but provision has been made for as many more. The furnaces are of brick and are coal fired, being closed at one end and having two doors at the other. The process used ot this mill is known as box- annealing, the sheets being contained in pots while in the furnace. The annealing pots are made of cast iron and will hold about 12 tons each. The sheets are laid on the bottom of the pot, called the pan, and piled up neatly, flat. The cover is then placed over the pile of sheets and secured to the pan, the bottom being sealed with sand to keep the air out. It is important to have as little air as possible in the pot. The pot is now lifted by the overhead crane, laid on cast iron balls and pushed into the furnace. The floor of the furnace has tracks upon which the balls run.

When the furnace is charged, the heat is applied until the whole mass, both pots and sheets, is red hot. The fire is then reduced, but the sheets are allowed to remain in the furnace a few hours longer to partially cool, at the end of which time the fire is banked. The time occupied in this operation is about 24 hours firing and 15 hours partially cooling or soaking. The charge is now withdrawn and the annealed sheets are allowed to stand for about 24 hours in the pots, after which the covers are removed and the sheets allowed to stand until cold enough to handle. The sheets are then removed from the pan and laid on the floor to finish cooling. If they are to be shipped as black close annealed they are ready for final inspection and the warehouse. If they require cold rolling they are carried back to the cold rolls at the other end of the building. The extreme heat in the annealing furnaces ranges from 1,300 to 1,500 degrees Fahr., this temperature being maintained for about three hours.

The final operations which consist of marking and bundling are performed in the warehouse which it will be remembered comprises one bay of the main building. When the sheets are taken from the cooling floor they are weighed on factory scales in the warehouse and laid in piles according to size and gauge. To facilitate handling the sheets are made up in bundles, each bundle weighing about 150 pounds. Each bundle is marked, giving the size, gauge and weight per foot, the company's trade

(Continued on page 12.)

The Gas Industry and Canada's Fuel Problem

Dealing With the Great Strides That Have Been Made in the Manufacture and Use of Gas For Both Home and Industrial Purposes—Its Uses Defined and Why it is More Economical to Many Industries When Every Phase of the Business is Taken Into Consideration

By Arthur Hewitt General Manager Consumers Gas Co., Toronto.

THE condition which prevails in Canada to-day, with regard to the supply of fuel necessary for the maintenance of the industrial activity of the country, and for the domestic requirements of its population, demands a careful survey on the part of Governmental authorities, and that every possible economy be exercised in order that the total requirements of fuel may be reduced to a minimum.

The fuels available for use in Canada may be generally stated as coal, wood, petroleum, gas, and water power electrically distributed. Each of these fuels has certain inherent advantages and their economic value is largely determined by the service to which they may be applied, and the localities in which they may be required.

In considering the economic value of various fuels on which Canada may rely to meet its domestic and industrial requirements, manufactured gas, or what is sometimes called "City" gas, must be given an important place. Originally used only as an illuminant, gas has become one of the vital necessities of the domestic and industrial life of urban communities throughout the civilized world.

In using the term "City" gas, I mean gas as ordinarily manufactured by gas companies, and distributed through pipe line systems laid beneath highways of cities and towns. In the early days of the industry, this commodity was called "Coal" gas, for the reason that it was produced entirely from bituminous coal. The qualifying word "City" may be appropriately prefixed to the commodity as now supplied in recognition of the fact that economic considerations have caused different localities to combine with the coal gas what is known as carburetted water gas. Indeed, in many cities on this continent carburetted water gas now forms the whole of the supply.

For practical purposes, however, there has been very little difference in the general character and useful properties of city gas, during more than one hundred years.

The tremendous development and growth of the gas industry, particularly during the past ten years, furnishes abundant evidence of appreciation by the public of the merits of the commodity supplied, and of the economy in the use of gas for the thousand and one purposes for which it is now so well adapted.

Its success in holding the market against all rivals of the same order of utility is due, largely, to its possession of certain valuable and unique physical properties, viz:

(1) It is a permanent gas, suitable for consumption in or out of doors, either as an illuminant or as a smokeless fuel of high or low intensity, or as a source of motive power; all from the same supply system.

(2) It is susceptible of perfect subdivision without loss of efficiency for use in either required application for lighting or the production of heat or power. The cost to the consumer is always in direct proportion to the quantity consumed.

(3) It is a readily available fuel, cleanly and inoffensive, to be obtained by the turning of a tap, which will grill a chop, boil a kettle, or heat a flat iron, and there is no metallurgical or smith's work for which its heat is not adequate, no household warming for which it is not suitable.

City gas as supplied in Toronto is made by the distillation of Youghiogheny and Westmoreland coal, obtained in the Pittsburg district, with the addition of about 40 per cent. of carburetted water gas.

At this point it might be interesting to see what a gas company can secure from a ton of bituminous coal.

In the first place, a ton of gas coal in an efficient carbonizing plant will yield ten thousand cubic feet of gas, from which may be extracted a certain percentage of benzene and toluol. It will produce approximately 1,350 lbs. of coke, from which, after providing the necessary fuel for the producers, there will be left a residue of from 800—850 lbs. of coke to be marketed as fuel for steam raising, industrial purposes and for domestic use. It will yield ten Imperial gallons of tar, from which may be recovered toluol, benzene, fuel oil, acids, dyes, etc. Another important by-product is ammonia, useful in the manufacture of fertilizer, and for refrigeration and other purposes. There is also, as a minor by-product, retort carbon, which is used in the manufacture of carbon electrodes for searchlights, electrical steel furnaces, etc.

It is estimated that the percentage of efficiency obtained from coal in a gas works will run from 60 to 70 per cent. Compare this with the efficiency obtained in general practice from a ton of the same kind of coal used in an open fire which has just been fed with coal. Would the efficiency be 20 per cent. or less?

Let us make another comparison, and remember that the object of our discussion is to find the most economical way to use fuel, and especially coal.

The available supply of anthracite coal is admittedly limited, and the need for conservation is probably greater with regard to it than is the case with any other kind of fuel. From every thousand tons of bituminous coal which a gas company carbonizes it produces and makes available for general consumption, as a substitute for anthracite coal, four hundred tons of gas house coke. The value of coke, as compared with anthracite coal, may be observed from the following analysis:

	Anthracite Coal	Coke
Moisture (after air drying)	3.20	1.60
Volatile combustion	6.86	8.27
Fixed carbon	76.61	76.23
Ash	13.33	13.90
Sulphur	.92	.94
Gross B.T.U. per lb.	12800	12200

Gas for Lighting

Under the conditions formerly prevailing when gas was sold exclusively for lighting by its luminous flame, the criterion of its value to the consumer was its illuminating power, but since the introduction of the Welsbach system of gas lighting by the heating to incandescence of a foreign substance in the Bunsen or non-luminous flame of gas mixed with air, gas is merely burned as a fuel just as for the purpose of cooking, and generation of motive power.

Gas for Cooking Purposes

Aside altogether from the cleanliness, ease of control, reliability of quantity and quality of supply, in which respects it stands pre-eminent, in point of economy there is no fuel which at prevailing prices can begin to compare with the cost of gas for certain kinds of service. If gas exclusively were used for cooking in the City of Toronto there would be a large money saving to the consumers, but more important than this saving would be the economic advantage gained by having to import so many tons less of anthracite coal.

Gas as Fuel for Industrial Purposes

A great deal has been said from time to time as to the insanitary conditions of the atmosphere in our city, caused by the discharge of black smoke from chimneys. In spite of by-laws, and the watchfulness of officials concerned with their enforcement, the evil seems to remain unabated, with every prospect of conditions becoming worse with the further growth of the city.

The problem of furnishing power, without making smoke, is rapidly being solved by the use of water power, dis-

*Read before the Canadian Society of Civil Engineers, at Toronto.

tributed by electric lines. The use of coal in manufacturing processes, however, is still to be considered. Here the gas industry offers a means for the displacement of crude heating, which not only disestablishes the chimney as a polluter of the atmosphere, but introduces into the factory itself a controllable and uniform system of heating, producing constancy of result, and adding materially to industrial economy by the reduction of labor, the promotion of cleanliness and the speeding up and improvement of factory output. These aspects of the case require the main part of our consideration, but without going into details we might well consider also the great destruction of value for which the present crude methods of heating in factories are responsible. While gas can supply heat so easily controllable that there is comparatively little waste in obtaining from it effective duty, with coal there is necessarily a large waste of heat. There is a large amount of heat wasted in effecting its combustion, and in driving off those volotile constituents which are useless where high temperature and pure incandescence are required. There is also waste of heat up the chimney and through stand-by requirements. There is waste of heat every time a fire is re-charged until once more favorable working conditions of the fire are obtained. With the gas as fuel, the heat can be directed exactly as needed into the furnace, and heat losses by radiation and otherwise can be reduced to a minimum.

I do not say that coal can be entirely displaced in factories; but I claim that a large part of it could be. The point I wish to make is, that, in addition to air pollution, our industries are largely wasting, by their crude methods of heating, parts of the substance of the country which are necessary, more necessary to-day than they ever have been.

If these statements are correct, it can readily be seen how vast an opportunity there is to benefit the country at large, if we are able in any appreciable extent to do away with this waste. In case of any doubt as to the practicability of accomplishing this result, I believe that when it is seen how much has already been done, in developing gas appliances to supplant the crude methods still so largely used, our knowledge of possibilities will lead us to believe that we see only the dawn of a new era in industrial heating.

The manufacturer has his point of view in this matter. It is not sufficient to explain to him how the use of gas will benefit the community, it is necessary to show him that it is to his direct benefit as a manufacturer to adopt the modern methods of using heat in his processes. Some of these advantages are:

1. Economy in space occupied by appliance, and in some cases the necessity and expense of a smoke stack is avoided; a practically unlimited choice of a position for the furnace, which enables it to be brought into close proximity to the machine workers.

2. No space required for storage of fuel, and no removal of ashes.

3. Increase in output per cubic foot of factory space, owing to economy of space occupied by gas furnaces in comparison with coal furnaces.

4. The constant and unvarying supply of fuel, of a uniform heat value, at a fixed rate.

5. Labor saving—absence of stoking, storage and conveyance of fuel.

6. Rapidity, and improved production, due to ability to precisely control working temperatures.

7. In many cases a lower capital expenditure for installation.

8. Cleanliness, which frequently assists in decreasing net labor cost.

9. No interest to be paid on investment in fuel in storage.

10. Reduced fire risk.

11. No loss of material due to inability to check a high temperature instantaneously.

12. Less repairs on equipment.

13. Enormously smaller loss from articles or materials being spoiled by irregular heat.

When these points are taken into consideration, it is really astonishing how many instances there are where the total cost of manufacturing is less with gas than with coal.

The following list contains but a few of the hundreds of successful gas appliances available, and in use, and while the consideration we can give to each will be necessarily brief, it will give a fair idea of the accomplishments in this field.

Baking Ovens.—The use of gas for baking bread and pastry in small bakeries, restaurants and institutions has proven very satisfactory. With large bakeries, however, although some progress has been made, there is yet much more business to be secured for gas.

Japanning Ovens are of two general types—the direct heated, and the indirect heated. In the direct heated, the fuel is allowed to burn in the japanning compartment; in the indirect heated, the fuel is burned independently of the japanning compartment, the products of combustion being carried up through radiators placed at the sides of the oven, and then carried out through suitable flues. Gas is superior to steam for heating japanning ovens, where temperatures from 150° F. upward are required. Gas is superior to coal on account of its cleanliness, time consumed in getting oven ready for baking, dust and dirt incidental to the use of coal, and for many other reasons. With the use of gas, temperatures can be exactly regulated according to requirements, while a coal fire is not capable of being so regulated.

Heating Liquids

Glue Heaters—The heating of glue is one of few processes where the difficulty is not that of getting enough heat, but of getting too much. Glue should not be heated over 150° F. If it is heated to the boiling point of water it is practically ruined. It is hardly necessary to say that the ease with which an exact temperature is maintained by the use of gas puts this fuel in the first place as a means of heating glue. The appliances are quite simple—just one or more pots of suitable size, suspended in water, the water being kept hot by means of a small burner. There is also a contrivance supplied with a mechanical agitator, which is useful in assisting to dissolve the glue.

Cauldron Furnaces.—These are constructed either round or rectangular in shape, and are generally direct-fired, in which case the gas burner is placed immediately below the cooking cauldron. Sometimes, where the materials to be heated will burn easily, a water compartment is interposed the same as with glue heaters.

Cauldron furnaces are made in sizes ranging from five gallons up to 150 gallons, and sometimes even larger. They are extensively used, and with almost universal satisfaction. Some of the uses to which they have been adapted are as follows:

Rendering lard, scalding chickens, heating potash, making disinfectants, making face creams, cooking meats, making marmalade, jellies, etc., canning fruits and preserves, boiling syrups, metal polishes, wax melting, grading oils, making pastes, making soap, heating water, dyeing, cooking potato chips, making soups, making soft drinks, etc., making catsup, pickling vegetables.

Bakers' Fryer—This is practically the same as a cauldron furnace, except that some manufacturers supply simply a burner and frame without the cauldron, thus allowing the customer to use the same utensil which was formerly used on the coal-heated stove. It is used for frying crullers, potato chips, etc.

Confectioners' Furnace.—The success of the process of boiling candy is mostly one of securing the right temperature. A certain amount of moisture must be driven off from the original mixture of sugar, water and other ingredients before the proper temperature can be reached. The gas consumption varies from 1½ to 3 cubic feet per pound of candy, according to the temperature required.

The gas confectioners' furnace has many advantages over furnaces using coal or coke. Cleanliness is one of the most important items in a place where candy is being made. Of course there is absolutely no dirt from the fire when gas is used. The furnace is always ready for immediate use. It makes the keeping of the factory cool, in summer, much easier. If a proper gas furnace is used, a great deal more work can be turned out than with the best coal furnace. The heat can be regulated at the will of the operator, which cannot be done so readily with coal.

DEMAND FOR BALING IRON IN NEW SOUTH WALES

Users of baling iron such as is required for use in dumping wool bales report a great scarcity of this commodity. The size used is 15-16 of an inch and the gauge 20.8. It is shipped in coils of approximately 56 pounds, and a recent quotation from the United States was £74 per ton, c.i.f. Sydney. Delivery subject to space being available .

Russia's Need of Imports and the Resources Available for Payments

Lack of Stable Currency Not an Unsurmountable Barrier — Present Fluctuating Values Militate Against Cash Payments—Exportable Products Still Plentiful

By Sterling H. Bunnell in *Russia*
Chief Engineer, R. Martens & Co., Inc.

EVERYONE interested in the triumph of the forces of democracy in the war agrees that Germany must not be permitted to obtain either permanent military control or any degree of commercial domination over Russia. Lacking necessary factories and industries adequate to supply the country's needs, Russia can be rescued only by Allied aid from becoming the broad base of a towering pyramid of Germanism from which the Hun can launch his next attack on civilization. In some form or other, assistance must be given by Allied countries so as to free Russia from economic dependence on Germany. Large exports must soon be started for Russian ports, to supply the most pressing civilian needs.

A Misconception

Any idea among American business men that Russia is commercially finished, and that her international trade is dead, is founded on misconception. Russian paper currency is in truth almost worthless in foreign trade, though used freely in domestic interchange. But exported goods are not usually paid for in foreign currency.

If a country should continue to buy goods from abroad for money, it would in time pay out all its gold and silver money and lose credit for its paper notes. Continuing export trade must be balanced by import trade of equal value. Part of the value, either outgoing or incoming, may be paid in labor of citizens for foreign countries, or in services rendered tourists from abroad, or even in gold money, if the citizens can keep up the supply by mining gold.

The lack of a stable currency in Russia makes it difficult for an American manufacturer to come to terms with a buyer in Russia, but does not make international trade impossible.

Trade Factors

The Russian citizen with earnings or income in rubles wants to use his funds in buying clothing, boots, or other necessary articles which must come from abroad. The only obtainable articles, however, are Russian raw products, hemp, flax, skins, and the like. The American manufacturer of the clothing or boots wanted in Russia must receive dollars in return for the purchase of materials and payment of labor. Other American manufacturers want the hemp, flax, etc., which Russia has for sale, but may not pay for them in gold while Russian exchange is fluctuating so that the real dollar value of a shipment is very uncertain.

There are thus four different parties, all wanting to engage in international trade, but no one of them in position to complete the transaction by himself. In normal times each one could make his trade by the aid of the foreign money exchange brokers—under actual conditions, only international banking and exporting firms are in position to balance trade against trade and so restore trade with Russia.

In spite of the utter disorganization of Russian production during three years of active warfare, the country is by no means destitute of exportable products, nor have the invading Germans access to all of the supplies. A considerable portion of Russian exports comes from Siberia, and has been accumulating, at a decreasing rate, for three years. It is not probable that German penetration and influence will extend even as far as the Ural Mountains. Siberian goods are likely to remain available for export to the eastward if Allied manufactures can be had in exchange; otherwise they will eventually reach Germany. American importers and manufacturers in need of raw materials from Russia should put themselves in communication with reputable firms having export connections for the double purpose of supplying their own wants, and of counteracting the German commercial threat.

A New Period

The direct exchange of exports for imports will begin the new period of trade with Russia. The movement toward restoring the trade balance will be assisted by the coming industrial development of Russia by foreign capital. In the chaotic period since the Revolution, more than one large Russian industrial plant has passed from Russian to foreign ownership; each such transaction requires a payment to Russia from foreign countries, and so offsets a portion of Russia's foreign indebtedness.

Russia to-day may not appear to the uninformed as an attractive field for investment, but those who know Russian possibilities and conditions are already buying up established industries and investigating prospects for creating others. Mines of coal, iron, and valuable metals; oil wells producing red or white naphtha fit for use without refining; railway concessions opening up untouched territory, and enormous possibilities of agricultural development by machinery on a large scale, are already passing to foreign ownership.

Early Action

In these ways trade will find for itself a method of helping Russia out of present destitution. Undoubtedly, the requirements of the Russians are so great that the sale of already existing products and property will not by itself provide funds sufficient to make Russia again an independent, self-supporting nation. The important thing is to begin the process as soon as possible and carry it as far as the means allow. In due time sound counsels and stable government in Russia will facilitate reconstruction by liberal laws, and will arrange for international loans by Allied countries so that refitting Russian industry can proceed freely.

In theory, perhaps, the Russians are down and out and cannot buy anything. The condition of the people, however, is such that they must have goods, and therefore they will find ways and means of buying them.

A SUBSTITUTE FOR CORRUGATED IRON

Efforts to practice economy in the use of steel and iron have developed and are now resulting in a satisfactory substitute for corrugated iron and sheets. It is an asbestos-cement roofing material. During the last year a large plant has been built in England for manufacturing this product. The method of making it is as follows:—After being finely ground and freed from extraneous matter the asbestos, which acts as the reinforcing agent, is mixed with Portland cement in the proportion of about 1 to 6. and made into a paste with water. This paste is then taken to a machine of the paper-making type, where on a large revolving drum it is formed into sheets or felts. After the sheets have been trimmed to size, they have the corrugations impressed on them. The important condition for this operation is to insure that the tops of the corrugations are as strong as the other parts of the sheets. Finally the sheets are subjected to a "seasoning" process. The corrugations are made to the 3-inch pitch which is usual with corrugated iron sheeting. not to the 2½-inch foreign pitch, and they can, therefore, readily be used to repair roofs of corrugated iron. The sheets are also fireproof and are poor conductors of heat. Corrugated asbestos-cement roofing of this character has been made in Canada for a number of years at Lachine, Que.

The Design of General Purpose Agricultural Tractors*--II.

By Alan E. L. Chorlton, C.B.E.

Mechanical appliances are of great importance in the quantity production of foodstuffs so needed to-day. The following article deals with the problem of co-ordinating the widely separated pursuits of engineering and agriculture in the design of farm tractors and affords an interesting view of the problem as approached from the standpoint of English practice.

The Engine

ANY consideration of the engine must begin with the conditions under which it has to run on a farm, the inexpert attention likely to be given to it being an important factor. Generally, whilst this necessitates robust construction, it also calls for a low power rating or a considerable reserve of power, and probably the factors of low speed, large cylinder capacity for power required, strength and simplicity of parts are the main ones. That the engine must operate on kerosene is a sine qua non, and, further, it is preferable that it should develop its power without water injection.

The gain to be obtained by the use of crude oil in a high compression engine would justify the greater refinement of the engine, though there is greater difficulty in obtaining the fuel, kerosene being probably the most universally and readily obtainable of all oil fuels. On the other hand, such an engine running on kerosene would probably use up to 30 per cent. less, a very material and important saving, and one which should induce the engineer to persevere with this type; the fact that the automatic ignition of this type removes the risks of all electrical gear must be borne in mind. It should be quite possible, however, to secure better economies with the ordinary engine than are at present customary. It may be taken that the consumption per acre in practice is 3 gallons, often more, sometimes less. A 20-h.p. tractor has probably an average load of not more than five-eighths of the maximum, or, say, 12½ brake horse-power (see dynamometer readings—three shares, plus allowance for stoppages and headlands). Taking 2 hours per acre, this gives, say, 12 pints per hour, or 0.96 pint per brake horse-power. This result is not at all a bad one, and is probably much better than what is actually taking place in day to day work when the tractor is run by an ordinary farm hand. It should be possible to cut it down to 0.85 pint per brake horse-power, or with a high-compression engine to 0.6 pint or even less.

The type of engine used, whether vertical or horizontal, would in practice largely depend upon the plant of the manufacturer, four-cylinder vertical engines being naturally adopted by the motor-car engineer, whose factory is suited to that type; where factory considerations do not step in it might very reasonably be claimed that the horizontal type is to be preferred. It has frequently been found in practice with vertical engines not possessing vaporizing devices in the engine cylinder that some of the kerosene fuel passes the pistons and mixes with the lubricating oil in the crank chamber, with a consequent thinning of the lubricant, which causes excessive wear on the main and crank-pin bearings. It is not suggested that there are not many effective kerosene carburettors on the market, but rather that, despite these, with the class of labor available on the farm for operating the tractor, such action will frequently take place in starting up and on light load.

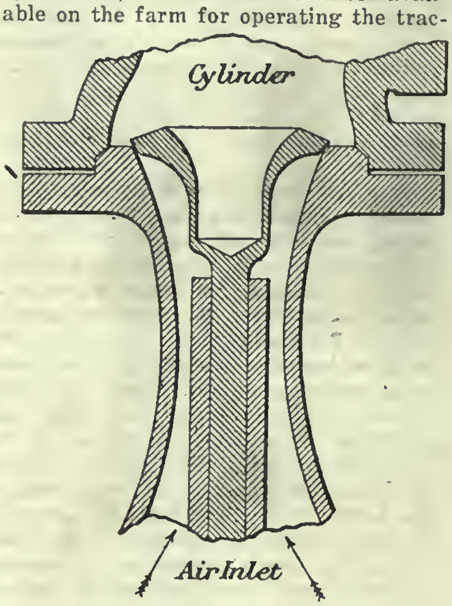

FIG. 10—KEROSENE VAPORIZER

The horizontal engine gets over this difficulty, inasmuch as excess kerosene will drain off through the exhaust valve before reaching the piston. A form of inlet valve which has been very successful is shown in Fig. 10. It will be noted that the hollow head, which is kept hot by the cylinder temperature, is arranged so that the entering gases in passing at a high speed through the venturi will impinge upon the hot walls; this forms an effective and compact vaporizer, and at the same time being in an inverted form, is self-draining. It must not be forgotten that the hot bulb engine can work with tube ignition, thus cutting out the electric installation, which is of all parts of the tractor probably the least understood by the farm hand; incidentally the running cost is reduced, as petrol is not required for starting up. Thus such an engine could be arranged to operate by tube with but trivial alteration in case of failure of the electric ignition.

The water injection, so often found in the high-speed engine of the vertical type, cannot be said to be conducive to long life; it was tried years ago in gas-engine practice and eventually dropped.

The vertical quick-running type can be and is manufactured at a less total weight, and this has been an additional reason for its use on light-weight tractors. It is, however, quite reasonable to ask whether, despite our being used to comparatively high-speed engines on motor cars and wagons where the average load is low, and the quality of fuel and the attention good, a speed of 500 r.p.m. can be exceeded under the conditions of farm service, quality of labor, heavy plowing loads and kerosene fuel, without a more than proportionate risk in wear and tear. Fig. 5 shows diagrammatically the two types of tractor, of which there are, of course, many variations.

Further, it is considered desirable that full power should be obtained with a mean pressure of only about 50 lb. per square inch, and that as in the horizontal type of engine the vaporizer should be in the cylinder head and allow of easy drainage for the use of low-grade fuels. A suitable arrangement has already been described in Fig. 10.

It is quite true that the high-speed engine reduces the weight of a tractor, but in view of the necessity of giving a reasonably long life under the conditions of farm usage, it is debatable if this is a wise policy. A comparison with a light-weight tractor on a basis of cylinder capacity indicates that these tractors obtain their light weight per horse-power largely by high engine speed and rating.

Type of Tractor	Wght. lb.	B.H.P.	Bore in.	Stroke in.	Revs. per min.	Np. lb. per sq. in.	Np. wght. tons	Vol. swept per min. cu. ft.	Vol. swept per B.H.P. cu. ft.	Vol. swept, wght. tons
Four-cylinder vertical light tractor type	3,000	25	4¼	5¾	900	67	50	340	13.6	254
Two-cylinder horizontal multi-purpose tractor....	5.600	28	7½	11	475	48	10	534	19.0	214

Flywheel Effect

It is very desirable to arrange for ample storage of power in the flywheel of the engine to provide for the momentary excess required when meeting hard places, whereby the engine is subject to less strain, and the fuel consumption should also benefit. In the horizontal type suggested the flywheel effect is sufficient to provide 50 per cent. power increase for about 30 seconds. In the light tractor with a quick-running engine there is usually considerably less power storage in the flywheel, and the engine must bear directly the extra demands and shocks.

*A paper read before the Institution of Automobile Engineers.

Cooling

Two methods are in vogue for cooling the engine—in the one the motor-car system, a radiator, fan and circulating pump are used, and in general the whole conforms very much to the standard practice in this respect. In the other system tank storage is adopted, the cooling of the motor being obtained through the loss of heat, due to evaporation from the open tank (the released latent heat, of course, effecting this).

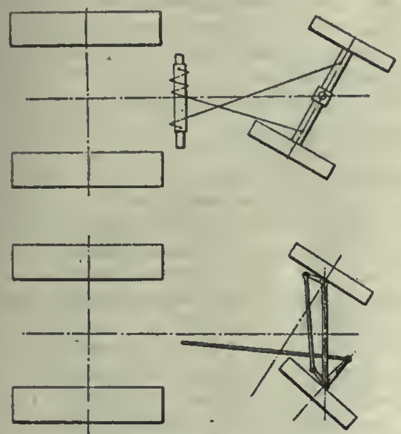

FIG. 11.—STEERING ARRANGEMENTS.

The tank system is simple and is more fool-proof in its working. It allows of almost any sort of water being used, such as is found in streams and drains about the fields, but on the other hand, it needs considerably more make-up water than does the radiator system. The advantage of the radiator system is the much smaller quantity of water needed, so that if water is scarce the saving in cartage may be considerable. Its disadvantage is that the radiator itself may silt up or in some way develop leaks. Both systems are used and probably local conditions will govern the choice.

Frame

The older type medium-weight machines employed as a rule a special frame built up of rolled sections, whilst later designs, in order to save weight, have incorporated the frame in the general design of the machine with advantage. This feature should undoubtedly be adopted in the design of a multi-purpose machine.

Gearing

The typical forms of gearing for the two types of tractors are shown in Fig. 5. In one we have the design based on the motor-car arrangement, using either bevel or worm gears, and with a high reduction on account of the high-speed engines, and in the other the design is based on that of the steam traction engine, in which neither the bevel nor worm is necessary: due to the cross-setting of the engine this type has not usually been totally enclosed. This feature, i.e., the total enclosing of the gearing and the running of the gears in oil baths, which originated in motor-car practice, should undoubtedly be incorporated in the other. As the test detailed in Fig. 7 indicated, the loss in the gearing is high, due probably to the exposed gears, want of alignment under load and insufficient lubrication. When the horizontal engine type is built with all its gearing totally enclosed, the efficiency should be equal to motor-car practice. As the reduction is less, and as no bevel or worm is employed, it is not unreasonable to expect from the horizontal engine a higher overall efficiency than from the high-speed engine design. The advantages of ball or roller bearings in the reduction of frictional losses are questionable. Published tests indicate but small bearing losses, so that any gain would be trivial.

Steering

There are two types of steering, the single and double pivot. The one is practically the standard in present agricultural machines, as steam tractors, etc., and the other is the standard in motor-car practice. The first is simple, cheap and strong in principle, and outside agricultural work it is chiefly used in steam-wagon practice. Yet despite this, there is a general tendency to adopt the double-pivot system for small tractor work, and this system, when centrally mounted so as to give three-point suspension, is to be preferred for the class of tractor under consideration (see Fig. 11).

Wheel Arrangements

Fig. 12 shows some of the arrangements of the wheels of tractors on the market for each of which the makers claim special advantages.

It is not proposed to enter into an examination of the claims of any particular arrangement, as they refer solely to land work and not to the road, their use on which is somewhat in the nature of a by-product. The need for a tractor to be an efficient machine for road work materially narrows the field of selection, and as long practice has proved that, for the power contemplated, the two-track four-wheel machine is the most suitable, this seems undoubtedly the one to be selected, as such a wheel arrangement is equally effective on the land. The size of wheels may be 3 ft. by 5 in. for front wheels, and 4 ft. by 12 in. for back driving wheels.

It is noticeable that there seems to be a tendency in tractors now coming into use to adopt rather smaller diameter wheels (4 ft.), probably with a view to reduce weight. There are two views as to the value of diameter and width, but it is not proposed to enter into these now. The matter was somewhat extensively gone into in a paper read by Colonel Crompton before this institution in April, 1913. and in an appendix to the same prepared by Mr. Leslie Hounsfield.

The caterpillar arrangement. whilst entirely suitable for special conditions on the land, cannot be considered as an advisable type for regular road work, and is, therefore. not discussed for the dual purpose called for.

In order to stand up to the road work the wheels of the tractor must be specially strong, though this naturally tends to increase of weight. It is true that, to save in the total weight of the tractor, light wheels might be adopted for work on the land, so designed as to be readily replaced by specially strong and heavy ones when the tractor is required to run on the road. In actual practice, however, it is probable that the inconvenience and time taken in changing such wheels, together with their considerable extra first cost, would very much limit, if not ultimately eliminate, any advantage there might be in this proposition, though it has been frequently suggested.

All axles for road locomation must be mounted on springs, and this can be readily done in the type of tractor adumbrated. A road engine, beside having all its weight sprung and the wheels of extra strong design, must in itself be so designed as to properly take care of the vibration set up by such duties.

Land Grips

As has been indicated, the projections attached to the rim of the driving wheels to obtain sufficient hold when plowing are an important feature, and their design to obtain efficient working is one of no inconsiderable difficulty; the paths traced by three different forms are shown in Fig. 6. The spuds must be of such size and form as to obtain effective hold on the land, and yet not set up too great an increase in rolling resistance by their shape; they should be self-cleaning, and so formed and fitted that, should the differential come into operation and only one wheel revolve, no such side force is set up as may cause the tractor to slip sideways at right angles to its path.

Generally the older forms of tractors, altrough they gave good service, do not appear to have received sufficient care in their design regarding the points discussed, and they frequently lacked the finished appearance of a complete design due to the apparently haphazard arrangement of the constituent parts, i.e., engine, gears, etc., on a rolled section frame.

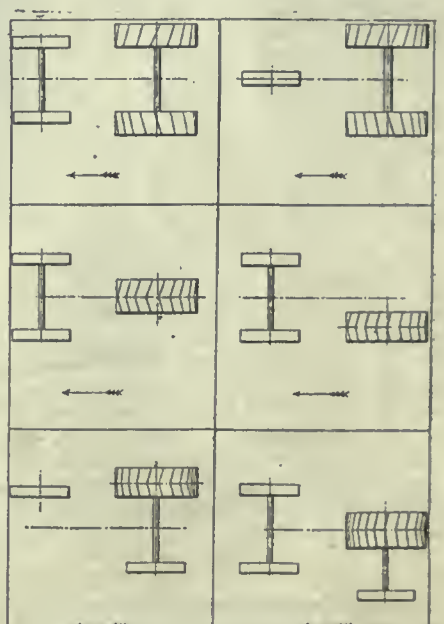

FIG. 12—WHEEL ARRANGEMENTS.

Progress in this direction has undoubtedly taken place, as is shown by the light type of tractor now coming on the market, in which a separate frame is obviated, and it is obvious that the design was completed at one time by an engineer trained with an eye to the appearance of the whole. Similar ideas might be incorporated in the horizontal type of engine, with undoubted advantage.

There are very many other questions and points of interest that might well have been discussed, and which the author would have liked to deal with, but the time at his disposal has been too limited to afford adequate treatment. He hopes, however, that sufficient data have been brought forward to start others upon the investigation of the problem of the agricultural power unit and to form the basis of a discussion to-night.

STEEL CO. OF CANADA

Continued from page 6.

mark is also stencilled on each bundle. The trade mark is the word "Stelco" on a maple leaf. For some orders the sheets are packed in cars and shipped without being bundled. Some orders call for the sheets being oiled before shipment, the oiling being done in the warehouse. The company manufacturers tack plate, which is made by the same process as black sheets but is not annealed.

Quality and Service

The operations involved in the manufacture of black steel sheets have now been followed from the raw materials to the finished product. The lay mind would hardly appreciate the amount of work and skill involved in the production of sheets or the great care that has to be exercised in every detail of their manufacture. Quality counts, and this can only be obtained by careful and systematic adherence to details in the various processes. Efficiency in operation is also a vital necessity if the proposition is to be a success financially. Judging from appearances at the plant the efficiency factor is high and consequently the results are in proportion. The consuming public in Canada will better appreciate the value of having a full supply of sheets available when normal conditions prevail and the company is in a better position to satisfy all requirements. As in other industries, the war is interfering with manufacturing operations to the extent that only a certain tonnage of steel can be allocated to the manufacture of sheets. In the sheet mill provision has been made for duplicating the existing plant, which will be done when the demand calls for larger production.

The Minimum Wage.—The minimum wage of adult experienced female workers in any factory in Winnipeg where foodstuffs other than candies are manufactured shall not be less than ten dollars per week, according to a statement issued by Dr. J. W. MacMillan, chairman of the Manitoba Wage Board. Exceptions are pickle, vermicelli and macaroni factories, where the minimum wage shall be $9.50 per week. Hours of labor shall not be more than nine hours a day.

Canadian Manufacturers' Association Meet in Montreal

THE annual convention of the Canadian Manufacturers' Association was held in Montreal on June 12 and 13. The principal features of the opening day were the president's address and a report of the tariff committee dealing with the United States embargo.

The President's Address

Defending the manufacturers against the charges of bolstering up tariff walls for personal aggrandisement S. R. Parsons, in his presidential address, declared:

"The profits of manufacturers, generally speaking, have been grossly exaggerated, and while here and there abnormal figures are shown (which are subsequently largely extracted by the Business Profits Tax), yet the large profits feature also applies in the case of agriculturists. The great majority, however of, these two classes, as well as of all other classes in the country, are simply making reasonable and necessary headway.

"The time has arrived when the government, members of Parliament and the people at large must be fair to the manufacturers of this country and not consider their interests as a football, to be kicked about by interested politicians and others, otherwise the national interests are sure to be adversely affected. The tirade of abuse has already gone too far.

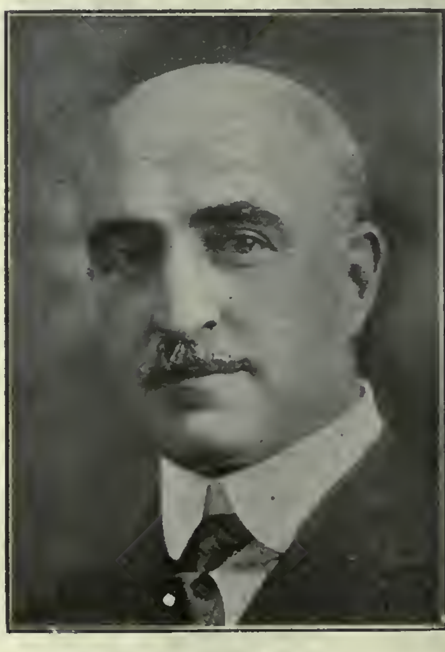
"In Canada, however, not only have we received no direct help and lead from the government in connection with planning for our industries after the war in the nation's interests, but a considerable section of our population is keeping the country in a foment of agitation which would tend to destroy rather than to build up.

"As far as export trade is concerned, manufacturers in Canada may be forced in the national interests to sell their wares at a merely nominal margin of profit so as to help preserve the balance of trade and at the same time give employment to the largest possible number of people. The crux of the situation calling forth denunciation of industry, we believe to be just here. Interested parties have poisoned the minds of agriculturists and other classes in this country and have led them to believe that the manufacturers not only received directly an enormous advantage from the tariff which they were not entitled to, and in consequence were making profits which were out of all proportion to the risks involved, but were also actuated by the most selfish motives. It is, therefore, opportune to say fairly, honestly and emphatically that the average net return from the investment of capital in industry is not more than it should be to encourage men to take the risks incident thereto.

Hostility to Manufacturers

"It would appear from the propaganda being waged with such vehemence against the manufacturers of Canada that the chief view presented is that the tariff is retained solely to benefit the manufacturers and to oppress all other classes of the people, the farming community in particular. It is, therefore, quite evident that the time has come when the manufacturers of this country can no longer keep silence, either in their own interests, the interests of labor, or the great national interests of this country. It should be remembered that the present tariff, with changes here and there, was enacted as a great national policy, not for the benefit of any one class, but for the well-being of the nation at large. Manufacturers feel that the tariff could and should be changed here and there, and so amended that it would apply more scientifically than it does at the present time.

"For this and other reasons the manufacturers would like to see created what might be termed 'a trade and tariff board,' such a board to be composed of



T. P. HOWARD

representative men of actual experience and wide knowledge of commercial conditions, and whose broad outlook and vision would fit them particularly for the proper study of these great questions so vital to our national interests."

Report of Tariff Committee

The report of the committee dealing with the United States embargo says in part:

"The tariff changes enacted by Parliament this year were designed wholly to meet revenue requirements, owing to the enormously increased government expenditure on the war. Your committee believes that no other action is practicable in the country's general interests, whilst the war continues.

"The mobilization work of the United States commands our highest admiration, but the very efficiency and nation-wide scope of this concentration on the one object of hastening the successful ending of the war has created temporarily critical conditions for this country, as in the case of war trade embargoes, which prohibit the exportation to Canada of various basic materials indispensable to essential industries.

U.S. Dominates Market

"Canadian industry has been built up in close relation with the growth of United States industry. We draw necessary materials from adjacent United States territory, just as an industry in one State draws materials from another State or from Canada. Now, however, a United States manufacturer is using materials which a Canadian manufacturer cannot obtain, and, in other cases a United States manufacturer is buying his basic materials at lower prices than the same materials, which are equally essential to his work can be purchased in the United States by the Canadian manufacturer.

"Since the United States still allows the product of such a manufactory, representing completely finished articles as sold to the ultimate user, to be exported to Canada, the manufacturers of that country are able to offer lower prices here than our manufacturers can meet. This works to create unfair domination of this market.

Complete Pooling of Resources

"The United States would be treating the Dominion of Canada no better than they treated it throughout the first years of this war, when they were a neutral nation, if they would arrange to admit Canadian manufacturers to their sources of supply under conditions which they apply to their own manufacturers. If Canadian industries were permitted to obtain indispensable materials in the United States on the same terms as govern their use by corresponding United States manufacturers this policy could not fail to produce better effort in the war work of North America. Full control of such equitable arrangements could be assured under regulations of the Canada War Trade Board.

"The effect of government encouragement to great imports of finished products from the United States seems to have been overlooked or disregarded. It increases the difficulty of the exchange situation resulting from the fact that the balance of our trade with the United States is heavily against Canada."

On the second day a number of interesting papers were read and officers for the year elected. The papers included one on Industrial Research, read by D. A. B. MacAllum, and "After-War Conditions," by the Hon. Frederic Nicholls.

Industrial Research

D. A. B. MacAllum, chairman of the Honorary Council of Scientific and Industrial Research, Ottawa, outlined the problems it is dealing with. He said:

"The only way to raise the vastly increased revenue due to the war was to develop the industries of Canada to the utmost."

He concluded: "I am not talking politics. I am not a free trader or protectionist. I do not wish to deride these questions. The question is, what are we going to do? We need revenue more than ever. How are you going to raise revenue without taxation? That is what one must do. Therefore this tariff question is now a live one, and it cannot be placed aside for other bigger and more important questions."

Prof. W. L. Goodwin, chairman of the Canadian section of the Society of Chemical Industry, followed with an ad-

W. J. BULMAN

dress on "Chemical Industry." He spoke of the intimate relation of chemistry to modern industry. In these days when manufacturing was carried on scientifically chemical control was the order of the day, and more and more it was becoming an underlying principle for manufacturers to seek the aid of the chemist in carrying on their business. So much was this so that the universities where chemists are prepared had been utterly unable of late years to meet the demand for graduates.

After-War Conditions

Senator Nicholls, of Toronto, spoke of preparation for after-war conditions, on which subject he has been extremely active. Since the war, he said, exports had increased 254 per cent., of which increase manufactures provided 50 per cent. more than agriculture. While the 404 million increase in agricultural exports was subject to but little taxation the 600 million increase in manufactured goods exported was subject to taxation and super-taxation. It had done much to enable Canada to bear her war burdens.

"But after the export trade passes with the war where are we going to get the money to pay the war bills? It is up to us and to the government of the day to give us a lead in making preparations to meet the conditions we will surely be called upon to face," he said.

"The only way to prepare for after-war conditions in retaining our export trade in articles we manufacture now or can adapt ourselves to manufacture as we did in the case of munitions is by co-operation between the government and the manufacturers. This would eliminate trade jealousies and secure the respect and prestige which a quasi-government organization always secures."

After reading his own correspondence with the Prime Minister and other members of the Cabinet, in which he urged the government to take action in preparing for after-war conditions, Senator Nicholls asked the association to pass a resolution supporting this campaign, which it did.

Officers Elected

The following officers were elected: W. J. Bulman, Winnipeg, president; T. P. Howard, Montreal, 1st vice-president; J. S. McKinnon, Toronto, 2nd vice-president.

The association passed the following resolution in reference to after-the-war industrial operations:

"That the Canadian Manufacturers' Association, in annual convention, resolve:

"That the Government of Canada be urged to take prompt action towards making provision for the past war trade conditions to the end that the present favorable balance of trade may be continued and that the employment of several hundred thousand people now in war industries may not cease.

"That this association is further of the opinion that the plan outlined and submitted to the government by the special committee of the Senate on the conservation of Canadian trade or some modification thereof would, if adopted, result in permanent benefit to the country at large and also be of material assistance in the financing of our great national obligations."

Resolutions were also adopted: (1) Favoring government assistance for industrial and scientific investigation as a number of concerns have guaranteed financial co-operation on a considerable scale for a period of years, provided government action is forthcoming; (2) urging municipal, Provincial and Dominion Governments to seriously consider the whole question of housing reform towards the increasing of adequate housing facilities and the increase of house ownership, and (3) recording the association's deep appreciation of the work of the Commission of Conservation.

Principles & Practice of Mechanical Sketching & Drawing-III.

Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simpler Types—A Practical Course Prepared Especially For Younger Men and Newcomers in the Industry

By Terrell Croft

Application of Calipers and Squares

THE combination square is sometimes usual in obtaining longitudinal dimensions. It may be utilized as indicated by using the regular head on the blade. One end of the object being measured rests on a surface plate. The head of the square is pushed down on the blade until it indicates the exact value of the dimension desired.

Internal dimensions are measured with the inside calipers. Fig. 16 shows the draftsman setting his calipers to the inside diameter of a pinion. After the calipers have been set to the required diameter, the linear dimension corresponding thereto is obtained from the scale as in Fig. 17. The end of the scale and the tip of one of the caliper legs are held against a surface plate. At the other tip of the caliper leg the required dimension is read.

In measuring external diameters with a caliper the procedure is that explained graphically in Fig. 18. The draftsman, by turning the thumb nut on the caliper, alters the distance between the two legs until the tips just touch the circumference of the surface to be measured. The

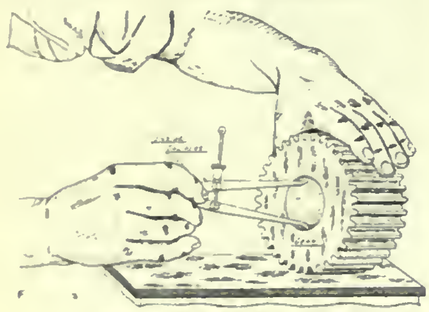


FIG. 16 USING INSIDE CALIPERS.

draftsman ultimately develops a sense of feeling in making these adjustments. With this sense of feeling properly matured, wonderfully accurate results are possible. The distance between the caliper tips having been made equal to that of the diameter required, the linear dimension is obtained as shown in and previously described in connection with Fig. 14 given last week.

External diameters of certain objects may be obtained with the combination square. This application is given in Fig. 19, wherein part of the object to be measured tapers. The use of the combination square on the surface plate insures that the diameter being taken is one at right angles to the longitudinal centre line of the object.

In determining the depth of a hole or slot the combination square fitted with the regular head can be utilized. In Fig. 20 is shown the method of obtaining the depth D of the slot in the object under consideration.

In finding the distance between centres of holes, where the holes are of equal diameter, the scheme shown in Fig. 21 can be applied. In some cases it will be

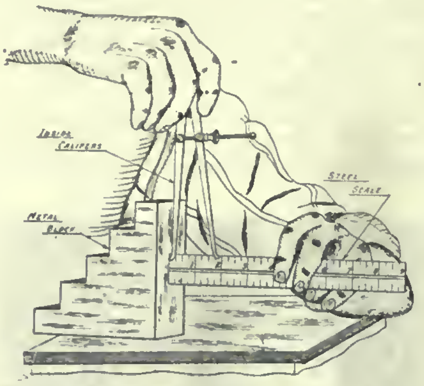

FIG. 17—METHOD OF READING INSIDE CALIPER SETTING

found that for this service the scale can be used as conveniently as can the calipers. That is, where the holes are of the same diameter, the centre to centre dimension is equal to that between the right-hand edge of one hole and the right-hand edge of the other. Where the holes are of unequal diameters, then the centre-to-centre distance equals the distance from right edge of one hole to left edge of the other plus one-half the diameter of each hole. To obtain the distance from an edge or surface of an object to the centre of a hole in it the procedure is this: Measure the distance from the edge or surface to the edge of the hole and add one-half the diameter of the hole to the distance thus obtained.

Using Combination Rule

In finding the centre of a cylindrical plane the combination rule equipped with a centre head is used as diagrammed in Fig. 22. Often it is necessary to thus

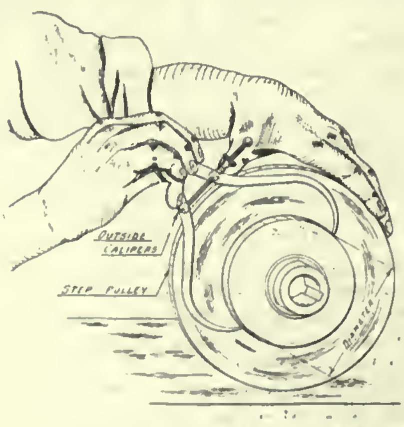

FIG. 18—FINDING AN OUTSIDE DIAMETER WITH OUTSIDE CALIPERS.

locate a centre so that radii may be determined therefrom. The rule with the centre head in position on it is first placed in the position AA and a line drawn across the end of the cylinder with the scriber. Then the rule—centre head in position—is turned to a location, BB, approximately at right angles to AA and another line is drawn. The intersection of these two lines will be the centre of the circle under consideration.

In measuring the angle of a beveled surface (Fig. 23) the combination square equipped with the bevel head is used. The head is rotated on its centre until when the blade and head are pressed against the surfaces under consideration the draftsman cannot see light between them and the surfaces or, at any rate, will see a line of light of equal thickness. Then the angle of bevel can be read from the protractor on the bevel head.

In taking measurements for lay-outs, that is, dimensions for plots for power-house or industrial plant drawings and plans, where the areas involved may be

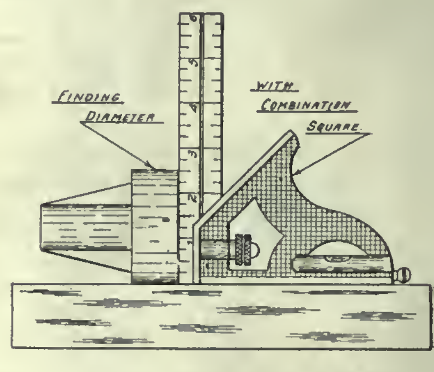

FIG. 19—USING COMBINATION SQUARE TO DETERMINE DIAMETER.

considerable, methods radically different from those described hereinbefore for relatively small objects must be used. That is, in lay-out work, the draftsman may deal in feet or even in hundreds of feet, rather than in inches. Hence, for taking the dimensions for lay-out sketches and drawings the tape line and the 6 or 8-foot folding rule are the instruments most commonly used. Often plumb bobs, for projecting down to the floor the locations of bearings, pulleys, shafts and similar members, are of great assistance.

Linear Dimensions

In recording linear dimensions in lay-out sketching the total distance from the starting point to the point under consideration, rather than the distance between points, should be recorded. This idea is shown in Fig. 24 which illustrates how the draftsman should enter on his sketch sheet or in his notebook the dimensions taken from the plot of the floor plan of an existing engine room. For example, at OF is the tape stretched to determine the locations of the window openings in the wall. The sketcher hooks the ring-end of the tape over the

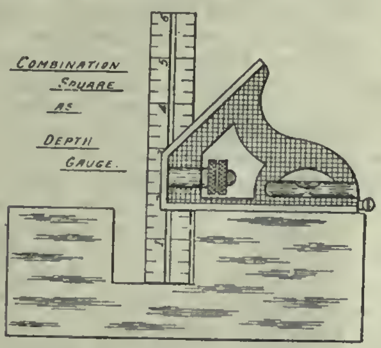

FIG. 20—USING THE COMBINATION SQUARE AS A DEPTH GAUGE.

nail at O and then proceeds along toward F, holding the tape taut. At each point which he wishes to locate on his sketch he reads the dimension from the tape. The dimension in every case is that between the point under consideration and the starting point O. For example, at A he reads 1'0", which means that A is 1 foot 0 inches distant from O. At point B he reads and records 3'6", which means point B is 3 feet 6 inches from his starting point, O.

Thus all of the points are recorded along the side of the room. When he returns to the drafting room and plots his lay-out to scale, he can obtain the dimensions for entry on his drawing in accordance with the usual method by subtracting successive dimensions from one another. The plan just described is the preferable one for lay-out work because it tends to eliminate errors. For example, if the sketcher were taking successive dimensions between points and

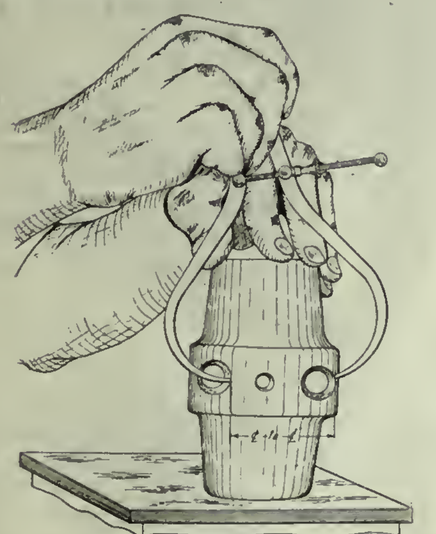

FIG. 21—MEASURING DISTANCE BETWEEN CENTRES OF HOLES ON A SQUARE BLOCK, WITH OUTSIDE CALIPERS.

measured incorrectly the distance OA in Fig. 24 it might render incorrect his entire sketch. But, if successive distances are read along the tape as explained even if several errors in observation or recording are made they probably will not cause trouble and can, in any case, be located readily. At GH in Fig. 24 is shown how the positions of the columns P, and P, could be recorded on the sketch. At IJ is shown how the location of the foundation F would be plotted. In Fig. 24 only the east and west observations are given. To complete the layout similar dimensions in the north and south directions would have to be taken.

TIME-STUDY

By A. W. Swan, B.A.Sc.

Every manufacturing plant has its own cost system, often very elaborate and held as a jealous secret; but when all is said and done any cost system boils down into knowing how long the various processes of manufacture take—and a careful assignment of the "overhead." All cost accountants will talk at considerable length of "overhead," machine-hour rate, and so forth, but it is surprising how many firms do not know the actual labor costs of their product, and here is where time-study comes in.

Time-study as a basis for bonus pay is well known, but all methods of bonus pay are for the purpose of increasing production by offering an extra reward, and it is very little use having a bonus pay system if there is no very well defined routing of work through the shop to avoid conflict of "rush" jobs. Right here time-study helps by giving the shop superintendent the knowledge of how long each process really takes, and by adding together the times for different operations dates for delivery can be set with considerable more accuracy than by the old—"Well, say the 20th of next month."

Type of Man Required

According to C. E. Knoepperl the "man for time-study must have tact, patience, accuracy, an analytical mind, a good imagination, constructive reasoning ability—which is rather a large order. But it is not quite such an easy job as the machinist is apt to think, and tact is certainly essential. For it is the task of the time-study man to get accurate operation times, to convince the men that it is to their own interest to work under a bonus plan, to be square to the men and yet not be led away into giving absurdly large "allowed times." He must avoid being fooled, and not lose his temper when he is, as he is sure to be sometimes.

Time-study will never work where the management is not trying to play square, but if the time-study is absolutely on the square, and the men begin to notice larger bonus amounts in their pay checks, they realize in a surprisingly short time that the company is not the only one to gain from a bonus system—and times will begin to get shorter—and with them of course the labor cost.

Time-study should by all means be open and above-board, the stop-watch soon becomes familiar to the operators, and there is no harm in telling them how the "allowed time" is calculated; in fact this has the advantage that the machinist can check up with his own observed time—and he usually will. Then the operator soon becomes convinced that all the time-study man wants is a good standard time, without hurry and without loafing. Of course, there are bound

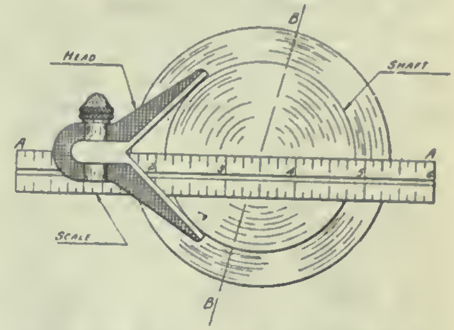

FIG. 22—METHOD OF FINDING CENTRE OF CYLINDRICAL OBJECTS.

to be attempts at trickery, but after a little experience they are not difficult to detect.

Taylor, Gantt, Bartth, and others have constructed slide-rules and charts for the guidance of the time-study man, advising him of proper speeds and feed for turning, drilling, etc.; but these should be used with considerable caution, as they usually represent the best practice with the best tool-steel, most convenient jigs and fixtures, and the most expert operators.

In the average shop these conditions are not found, and if used these rules should be adapted to local conditions by using a "shop constant" which the time-study man can work out for himself. In this connection it might be said that it is often a good plan to study the material provided by the makers of most machine-tools, who very often give

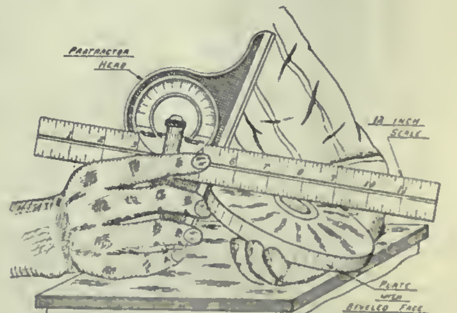

FIG. 23—METHOD OF DETERMINING ANGLE OF BEVEL BY PROTRACTOR AND SCALE.

speed tables and illustrate various "set-ups" in their instruction books.

Possibilities of Observations

Time-study certainly offers plenty of opportunity for anyone with a taste for research; in addition to working out ordinary machine times—comparing with the standard slide-rules, there is the matter of vise work; then time-study can be extended to the forge-shop and later, perhaps, even to the foundry. Then there is room for experiment with hack-saws—how the various makes of blades behave, how long they take to dull with rounds and flats, etc. But the largest field at present is certainly that which one might call "Elementary Handling Times." In the average machine shop there is no need to go the length of motion-study where every movement is analyzed, but the time-study man will find it a help to have a list of standard times for such motions as indexing the turret on a turret-lathe.

On the average machine-shop job on the lighter machines the handling time takes up a surprisingly large part of the total time on a job, and while it is easy to check up speeds and feeds, it is not so easy to check up the handling part of the work without some list of standard times.

As each time-study is made it should be filed, and should be easy of reference by having an alphabetical and numerical index. At the same time schedules should be made up for all machine-parts manufactured, having the operations in order. Then as the bonus system gets under way, and the average bonus made is known, it is a simple matter to know the actual time to expect on an operation compared with the allowed time, and hence to set delivery dates with certainty. Of course the actual average time for a large number of pieces on any operation will seldom be the studied time; it would be foolish to expect that it would, as there are always slight delays even to the best of workmen, and these should be allowed for in setting the "Allowed Time." However, there will be a fairly steady ratio between the allowed time and the actual average which can be used for date-setting purposes with very satisfactory results; and using the same information work can be laid out for a shop, assigning certain machines to particular jobs for a given number of days, and the work can be routed through the shop with far less delay than by the old method, and with a minimum of idle machines. At this point time-study connects up with the other important branch of modern production methods—routing and control—with which this article is not concerned directly.

It is highly important in all plants to have accurate labor-costs, and time-study will not give them directly, but if all the work is put on bonus and all time taken checked carefully, either by the time clerk or some mechanical system, the actual labor time and cost on every job is known, and comparison can be made in labor-costs as the lots go through.

It is advisable to keep records of times on all jobs, both for cost comparison and to see how time-study is affecting the plant. For estimating on new jobs time-study is absolutely invaluable, as no man can be on the job for any length of time without being able to estimate times for operations from drawings with considerable accuracy, and by adding together such times and allowing the average hourly rate in the plant, adding material cost and overhead as it is usually calculated, the cost estimate is not likely to be at all far out.

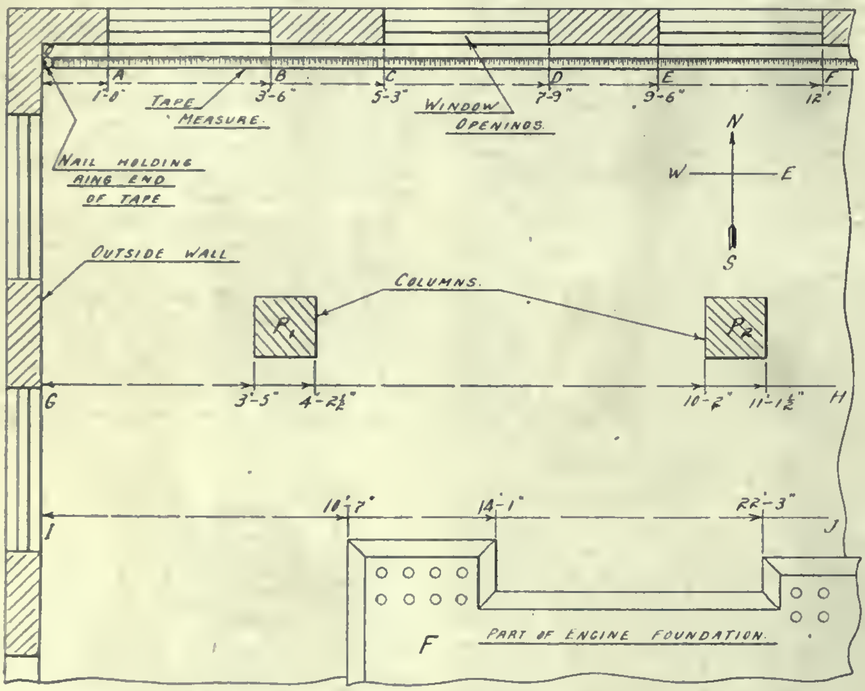

FIG. 9—CORRECT METHOD OF TAKING MEASUREMENTS BY STEEL TAPE.

ADVISORY RESEARCH COUNCIL FELLOWSHIPS AND STUDENTSHIPS

The Research Council was originally instituted to promote research in pure and applied science, and especially in those sciences which are related to the industries, so vital to a national prosperity.

Research in Canada has been largely suspended during the last three years except in a few of the leading industrial establishments and smelting plants. The staffs in the scientific departments of the universities have been greatly depleted by the enlistment of their members for military service, and those left, burdened with heavier teaching duties, have been unable except in a very few cases, to do more than carry out their routine duties. The effect of this on research work in Canada will prove to be very seriousfi unless measures are taken soon to supply the growing deficiency, for the interruption of the supply of recruits to the ranks of science must naturally curtail all research, both scientific and industrial, for many years to come. During the time of acute industrial pressure, often described as the "period of reconstruction," there will be so much demanding immediate attention that, inevitably, all questions of research will be pushed aside. Hence, the remedy is today not a matter of choice, but of necessity, for, if Canada is to maintain her position in the industrial world, she must immediately lay plans to maintain the supply of qualified men capable of carrying on those scientific investigations which produce new and sometines revolutionary methods and processes.

Research breaks up, roughly, into two main divisions: Research in the pure sciences and industrial research. It is impossible to draw a sharp line of demarcation between these two and he would be venturesome indeed, who would predict that a discovery in pure science would never be capable of industrial application, and, conversely, many discoveries of great note in the field of pure science have been made in industrial laboratories. Consequently, it is a traditional, rather than an actual, division that has been indicated.

In order to encourage in every possible way all branches of research in pure science, with special emphasis, of course, on those sciences which are likely to have industrial application, the council has instituted a large number of studentships and fellowships tenable at any of the Canadian universities, which are granted to graduates, or others, who, by their past records, have shown themselves capable of conducting scientific research. The studentships are of the value of $750 per annum, and the fellowships of $1,000 to $1,500.

To-day in the various Canadian universities there are, in spite of war conditions, eight students and fellows of the research council, who are actively engaged in investigations of importance to Canada. Among the subjects, which are of immediate public interest may be mentioned:

"Economic Utilization of the Tar Sands of Alberta."

"Utilization of Straw for Light, Heat and Power."

"Rubber Solutions and Colloids."

None of these researches has, as yet, been completed, but encouraging results have been reported by the investigators.

Copies of the exact regulations governing these studentships and fellowships may be obtained on application to the Secretary of the Research Council, Ottawa.

Vancouver. — The steel steamship Alaska, 8,800 tons, the largest steel steamship constructed in Canada, was taken from its launching berth Friday night. The trial trip of the vessel was made on Saturday.

WELDING A LARGE ALLIGATOR SHEAR FRAME

By J. H. Rodgers

ABNORMAL conditions are often mainsprings of unprecedented industrial developments, and these circumstances, coupled with the essential need of maximum conservation of certain materials, are undoubtedly important factors in expansion of many enterprises. The stupendous demand for iron and steel during period of war activities has almost if not entirely eliminated the so-called scrap pile; parts of machinery, and in some instances complete machines that in normal times would be considered as useless, have been given a new lease of life as a result of the great difficulty experienced in obtaining the required article in its initial state, from its original source. Probably no other agency in the wide field of engineering has done so much to reduce the size of the scrap heap as the art of welding, be it the blacksmith, the autogenous or the thermit process. Each method has its own particular sphere of usefulness, careful judgment being frequently necessary to determine which is the best system to adopt to meet the needs of the situation. However, it is reasonably safe to assume that for welds on heavy bulky sections of machinery the best practice to follow would invariably be the last mentioned, that of the thermit process.

An interesting repair by the thermit welding process was recently performed at the plant of the St. Lawrence Welding Co., of Montreal, views of which are shown in the accompanying illustrations. The casting here shown is that of a large steel aligator shear frame, broken through the central rib and the back housing, as a result of the upper jaw being forced sideways through careless work on the part of the operator. Owing to the inability of getting immediate delivery on a new casting it was decided to have the part repaired by welding, so the method here described was adopted and the repair successfully accomplished.

Preparation

In preparing the frame for welding it was located directly beneath a skylight to permit of free egress of the heat and gases, as the ceiling was low and of wood construction. Before proceeding with the placing of the mold, the oxy-acetylene torch was used to cut away the metal adjoining the crack, leaving a channel about two inches wide through the entire length of the broken portion; this being an essential feature in connection with welds of this character. The space thus provided is then filled with a special yellow wax which acts as the pattern; this wax is generally banked up above the ordinary level of the casting to provide additional metal at the broken section. This practice is not absolutely necessary, but where no interference will result the surplus metal is preferable as an added assurance of safety. During the preheating operation this wax is melted, leaving the hollow chamber for the fluid metal.

With the wax in position the sheet steel casing was placed over the broken portion in such a manner as would permit of placing the pouring gate and riser patterns in their desired location. This also applied to the heating gates, one of which was placed on either side and close to the bottom of the mold. Provision was made at the top of the mold in the form of a large basin, to carry the slag. When ready for preheating the crucible was supported above the mold by means of a girder placed across the skylight opening. The preheating apparatus, shown in the background of Fig. 2, is a Thermit gasoline compressed air unit for generating the gas required for the preheating of the broken section, preparatory to the actual welding operation. This particular type is provided with a device for removing the moisture from the air before the same mixes with the

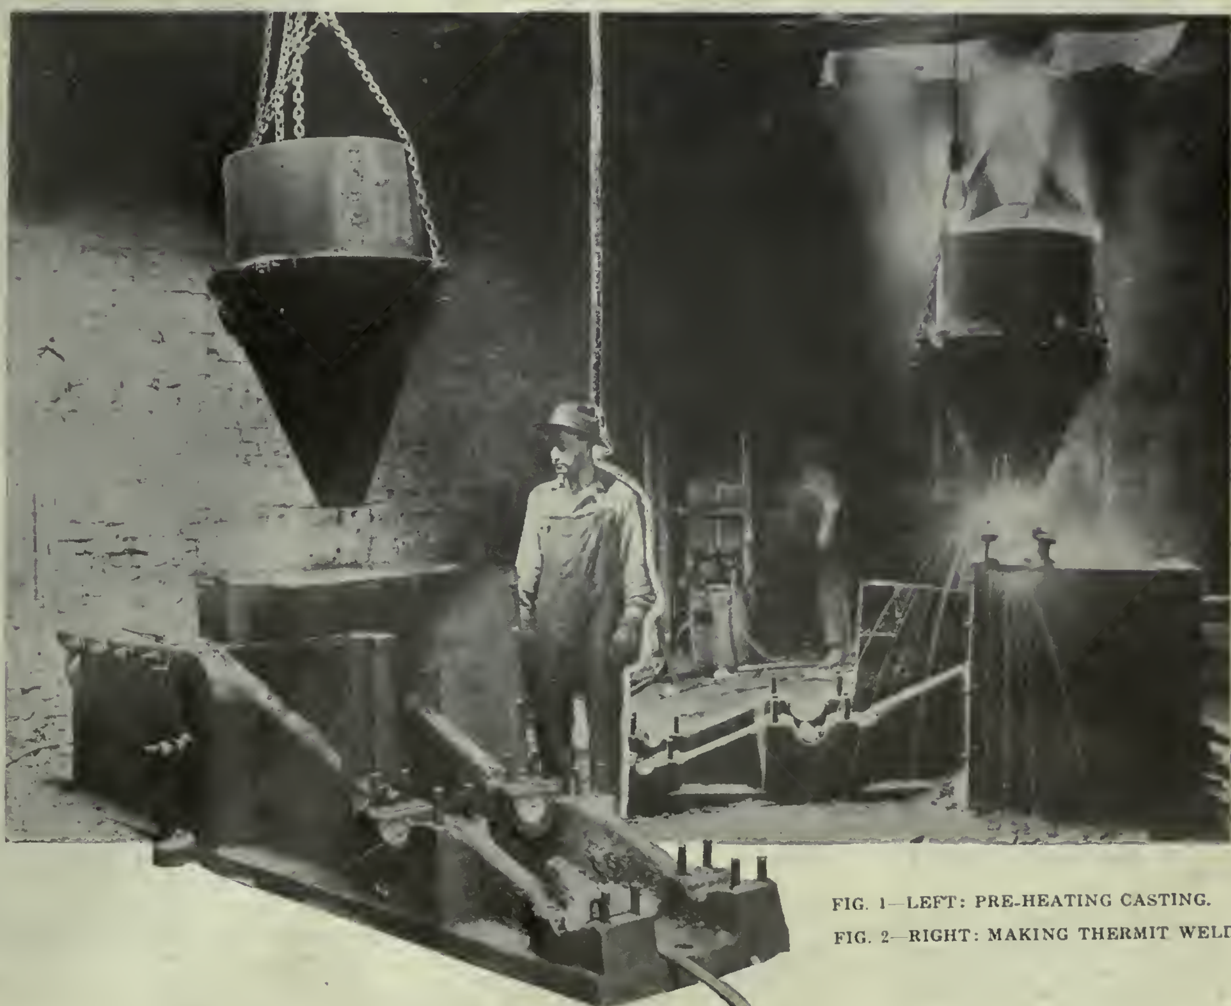

FIG. 1—LEFT: PRE-HEATING CASTING.

FIG. 2—RIGHT: MAKING THERMIT WELD.

oil; it is also equipped with two independent hose connections for operating two burners.

Preheating

The preheating on this job required considerable time, due to the heavy section of the broken portion and also to the fact that the pressure was insufficient to maintain a capacity flame at the heating gate. When the part was near the desired temperature the thermit—350 lbs. of which was required—was placed in the crucible, the latter being additionally supported on rails laid across the top of the molding frame. The burners were then removed and the heating gates plugged and banked with floor sand.

With everything in readiness the welder in charge places about one-half teaspoonful of the ignition powder on the top of the thermit in the crucible and then places the cone-shaped cover in position. A red hot rod is then inserted through the top of the cover and into the ignition powder, which is immediately ignited, and the chemical reaction is so rapid that within ten seconds the 350 lbs. of metal is converted into a molten mass at a temperature of over 5,000 degs. Fahr. In this particular instance, owing to the low heat of the casting before pouring, the metal was tapped less than ten seconds after ignition, so that the final stages of the reaction process would take place in the mold, thus assisting the fusing of the surrounding metal.

Detail Reference

Fig. 1 shows the work during the preheating operation, with the gas hose leading to either heating gate, and the crucible suspended in position. Fig. 2 shows the pouring process twelve seconds after the initial ignition. Fig. 3 shows a close up view of the finished weld with the pouring gate, riser, and one of the heating gates, before removal by the oxy-acetylene torch. The method of reinforcing the weld is clearly illustrated. The total weight of the casting was over 7 tons, and the completed weld was entirely satisfactory in every particular.

One of the great advantages of the thermit method of welding is the uniformity of expansion and contraction, a factor that is of vital importance in the greater number of machinery repairs, particularly where these are bulky and irregular in shape. The gradual rise in temperature during the preheating operation and the almost instantaneous distribution of the molten metal to all parts of the section to be welded virtually eliminates the possibility of internal stresses being set up in the material.

OPTICAL GLASS BEING MADE IN U. S. A.

Optical glass, although not required in large quantities, is nevertheless an item in war operations which is important because by optical instruments much of the firing. especially of artillery, is directed. If the men are not equipped with adequate fire-control instruments or can not see to aim properly, their firing can serve little purpose. A field army or a battleship without field glasses, telescopes and other optical instruments is manifestly placed at a serious disadvantage.

First Plant at Rochester

Before the war little effort was made to produce optical glass in the United States. Manufacturers of optical instruments were able to obtain optical glass in desired quantity and quality from Europe and consequently did not feel the necessity for making it themselves. In 1892, however, the Bausch & Lomb Optical Co., of Rochester, N.Y., built an experimental optical glass plant and placed a practical glassmaker in charge; by 1914 this company was able to produce a few types of optical glass which were used in optical instruments.

By the end of 1914 the importation of optical glass had become difficult and uncertain. Other firms, as Keuffel & Esser, of Hoboken, N.J., and Spencer Lens Co., Buffalo, N.Y., and the Bureau of Standards of the Department of Commerce, at Washington, began to experiment in making optical glass. By 1917, when the United States entered the war, the optical glass situation had become critical. The European supply was practically cut off. Optical glass had to be made in this country if our army and navy were to receive the fire-control instruments which they needed.

Produced in Quantity Now

The geophysical laboratory of the Carnegie Institution of Washington was called upon to aid in the production of high grade optical glass. A party from the laboratory was stationed at the plant of the Bausch & Lomb Optical Co. in April, 1917, and for seven months all efforts of the laboratory were concentrated at this plant. At the end of 1917 the essential details of the manufacture had been developed and glass in considerable quantities was being produced. The efforts of the laboratory were then extended to the Spencer Lens Co., and to the Pittsburgh Plate Glass Co., Pittsburgh, Pa. During this period the Bureau of Standards rendered effective aid.

At the present time, as a result of co-operation between the manufacturers and scientists, large quantities of optical glass of the kinds needed for military fire-control instruments are being produced of a quality equal in practically every respect to the best European glass. The need for a continuous and assured supply of optical glass is so great that the workmen trained in the details of manufacture and subject to draft are being withheld from draft in order that their technical training may be utilized at this time. The required information and details of manufacture and the skill necessary for proper production have been gained at great expense and under high pressure.

PROSPECTS OF ELECTRICAL INDUSTRY IN AUSTRALIA

Some interesting remarks on the present position and the future prospects of the electrical industry in Australia were made by the president of the New South Sales Section of the Electrical Association of Australia at its annual meeting held recently. He stated that the war had given a great impetus to the manufacture in Australia of electrical apparatus, and that large orders had been placed locally which would otherwise have gone abroad. Had the firms been quite prepared to execute the orders, they would have received a much larger volume of work.

Power is required for the development in New South Wales of large electro-chemical and electro-thermic industries, for which there is said to be a distinct field. It is probable that eventually the water powers of New South Wales will be harnessed in spite of the fact that coal is very plentiful, of excellent quality, and cheap.

Hydro-Electric Facilities

Considerable water power can be developed economically for the purpose of establishing manufactures, and the result of investigations shows that 100,000 kilowatts could be delivered on the sea-coast line, derived from the waters of the mountain ranges of the State.

This would enable producers to manufacture all products of the electric furnace, including not only steel, but carborundum and alundum as abrasives, graphite for electrodes, and to engage in the preparation of lubricants, calcium carbide for lighting, cyanide for fertilizers, alkali for all purposes, and, in all probability, aluminium.

There being no alternative—delivery being required soon—orders for electrical machinery have been placed with local manufacturers at exceptionally high prices.

When the war is over, however, the position will be altered. Active competition from established works abroad will be intensified owing to many manufacturing countries making a bid for the trade. Local factories will not be in a position for some years to manufacture on a large scale, and the only way of meeting this competition will be to impose a heavy protective duty or by reducing the cost of labor. A reduction of wages, however, is very unlikely.

MANUFACTURE OF WOOD-PULP IN THE STATE OF QUEENSLAND

The manufacture of paper pulp from Queensland soft woods has been commenced at Yarraman, Queensland. At present the manufacture is being conducted on a small scale and the pulp will be used by Sydney paper mills, which have already received 12 tons. The success of the operations is exciting keen interest in commercial circles.

A new industry is being started at Niagara Falls, Ont., by Lundy-Scott, Limited, who are now manufacturing collapsible fruit baskets, berry crates and egg crates, with new patent fillers. As a result of sending a sample to England, Lundy-Scott, Limited, received an order for two million baskets.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

HIGH-SPEED SHAPER

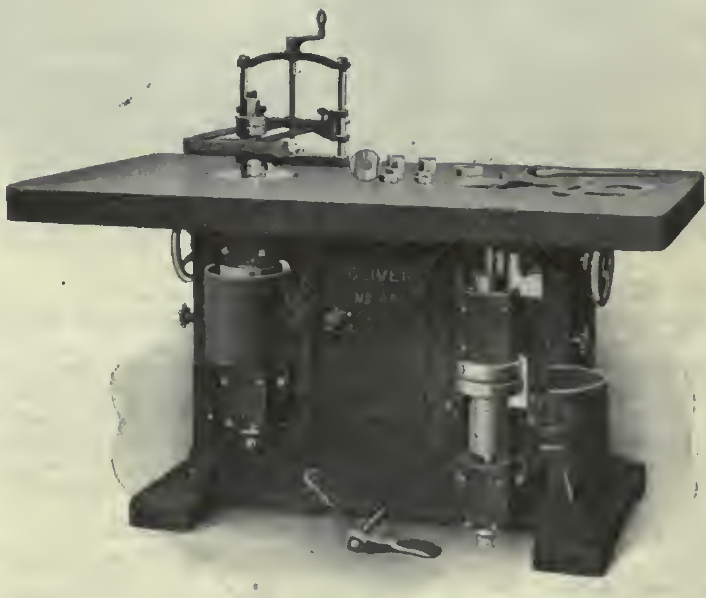
THE high-speed shaper illustrated is manufactured by the Oliver Machinery Co., Grand Rapids, Mich., and is well adapted to rabbeting, grooving, fluting, routing or shaping of any description.

The tables are large, very rigid, planed, and then accurately ground by a special process. They are bored out and fitted with three sets of rings, and are drilled and tapped for the guards.

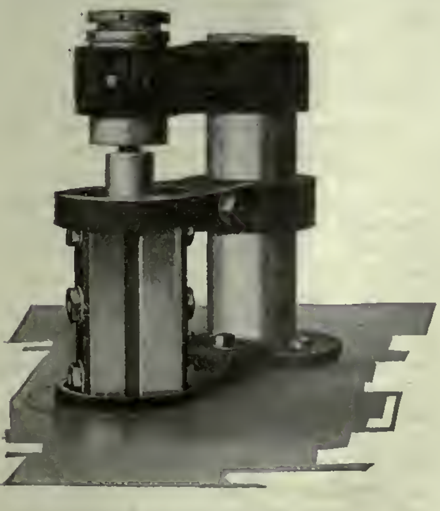
The spindles are tapered and are made of high carbon crucible machinery steel ground perfectly true on dead centres; guaranteed to run true. The spindles are regularly furnished to "run out."

The bearings are made of bronze, conical in shape, and are surrounded by oil chambers which lubricate the spindles the entire length of the bearings. The bottom of the spindle rides on a copper adjustable step, which is constantly washed with oil. A large brass drip cup catches the waste oil from the upper bearing. All adjustments are extremely simple.

Pulleys are carefully balanced, and are of the pneumatic type. The yokes are raised and lowered by means of the hand-wheels at the side of the machine, there being sufficient vertical adjustment to raise the spindle above the table or lower it beneath the tables. These yokes are very rigid and the screws for raising or lowering are directly in the rear of the spindle, affording them a direct support.



HIGH SPEED DOUBLE SHAPER.



EXTRA TOP BEARING.

The top bearings, with guides and supporting brackets are designed and particularly adapted to auto body or similar work. Top bearings are made of bronze and are adjustable. If desired these brackets can be furnished without the guides for furniture or column work.

A quick adjusting shaper guard is regularly furnished with each machine. Additional guards may be secured any time, as the tables are drilled and tapped for two guards. As shown by the illustrations, these guards are adjustable in all directions and are never in the way.

HORIZONTAL BORING MILL

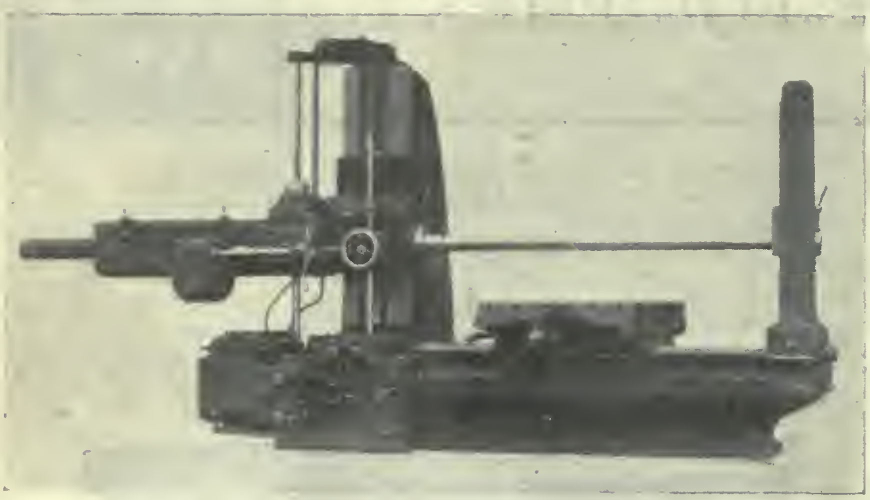
The illustration shows a recent product of the Defiance Machine Works, Defiance, Ohio. The boring mill illustrated is capable of a wide variety of work, being readily adaptable to milling, drilling and tapping operations in addition to the usual work performed.

The bed is of box construction, heavily cross ribbed, with the metal properly distributed to insure rigidity to all vital parts. The machine is entirely self-contained and rests on the floor at three points. The column is of box section flaring out at the bottom, to give a large bearing surface where it is bolted to the bed.

The spindle is of hammered high carbon steel, accurately ground its entire length, and slides through the spindle sleeve, while the spindle sleeve is a solid high carbon steel forging, with a conical journal at the front revolving in a solid bronze box, with an adjustable taper sleeve at rear. This arrangement makes it possible to take out all lost motion and permits the bolting of large milling cutters directly to a large flange on the end of spindle sleeve.

The spindle head has liberal bearing on the column, and instead of a narrow gliding edge on one side, the dovetail with taper gib is placed in the counter with actuating screw between. The two sides have clearance between the column, with straps at back. A gib on the front side is set up for free sliding fit, but helps to take any undue strain placed upon the head. A binder screw, back of the gib, locks the head rigidly to the column. The spindle head and tail block are raised and lowered together, being connected by a shaft and cut bevel gears. The tail block has long "V" bearings, which insures accuracy.

The spindle is driven through helical cut gears, which give the smooth motion to the spindle so essential in boring. Reversing with clutch is controlled by a lever convenient to operator, which makes it possible to use this machine for tapping.



HORIZONTAL BORING, MILLING, DRILLING AND TAPPING MACHINE.

The platen has large working surface with "T" slots of extra depth to insure strength. The gibbing to the saddle is of the square lock form, and a binder screw clamps the platen rigidly. A throw-out device regulates the movement of the platen. The saddle is extended out beyond the bed to give a good suport to the platen at its extreme point and rear positions. It is heavily gibbed to the bed and a tapered gib is provided for taking up.

The back rest carrying the tail block is mounted on a base, which contains the necessary mechanism. To accommodate long work, the back rest may be taken from the base by removing four screws without disturbing any of the mechanism and the base can be adjusted along the bed by means of a rack and pinion. A binding screw securely locks the base to the bed.

The feed is applied to the spindle in or out of the spindle head and tail block, up or down to the saddle along the bed and to the platen across the saddle. The two levers operate the shift with two sets of cone gears, four in one and three in the other, giving twelve changes of feed per revolution free of spindle. Another lever with convenient indexing device sets the spindle head, platen or saddle movement, giving the same feed wherever applied. A safety friction is placed in the feed box, which yields before any of the mechanism is damaged. It consists of a cast iron plate inside one of the feed gears, drawn up by a nut to the proper tension, and is applied at a point that it serves both in slow and fast travel. Fast travel to all parts having feed is obtained by a lever in a convenient position, giving the fast travel in either forward or reverse operation. Placed directly below is the lever for slow travel in either direction.

No countershaft is required with this machine, as it is a single pulley drive.

The spindle speeds are obtained by means of two cones of five hardened gears each, running idle ercept when one set is meshed by a roll-in hardened gear operated by a lever at the side of the machine within easy reach of the operator. These cones of gears are driven by back gears operated by a high-grade friction clutch located on the pulley drive shaft.

Hand adjustments are provided for movements of the spindle head, saddle and platen. The adjusting screws are all accurately cut, and are provided with dials graduated to one-thousandths of an inch in order to facilitate the production of accurate work

TRUCK FOR SHOP TRANSPORTATION

THE latest addition to the line of transveyors manufactured by the Cowan Truck Company of Holyoke, Mass., is their new Model G. This truck is of rugged construction and is a very easy elevating machine. The leverage is such that the maximum load can be readily elevated by one man. It is made in several sizes varying in capacity from 1,000 to 3,000 pounds. It is fitted with an improved locking device. This was chiefly designed to safeguard against the load becoming unseated when trucking over uneven floors. Various other improvements are incorporated in this new machine. The ease with which this transveyor elevates its maximum load, its quick operation make it particularly applicable to plants whose trucking requirements demand trucks of the abovementioned capacities.

TRACTOR TYPE TRUCK

The tractor truck illustrated herewith is manufactured by the Industrial Truck Co., of Holyoke, Mass. These tractors are manufactured in two types—an end control and a centre control—that is, a machine where the operator sits in the centre and can by changing seats operate in either direction without having to turn his tractor around. In congested or narrow aisles this is often a very valuable feature.

Either type steer on all four wheels and are built as two or four-wheel drive. The two-wheel drive machine can be converted to a four-wheel drive by the owner by purchasing the necessary worm and wheel housings, differential, etc.

The frame is built up of commercial rolled channel section steel; the bumper plates are of heavy boiler plate, bent on the corners and riveted solidly to the frame. The coupler castings are of the 3-step type to accommodate different heights of trailers. Battery boxes are constructed with easily removable side doors for changing batteries and hinged top plates for easy access for flushing or inspection.

Any type of battery can be supplied up to a maximum of 42 cells A8 Edison or 24 cells 21 plate lead.

The frame with battery box can be lifted from chassis by removal of four nuts, leaving entire driving mechanism accessible for inspection and repairs.

Power is transmitted from the motor through a single reduction worm and

TRUCK FOR SHOP USE

gear down through a differential and to the wheels by means of a rugged universal joint capable of operating at an angle of 43 degrees. This universal joint is enclosed in a patented dust and oil-proof case formed by the pivoting wheel knuckle and its supporting yoke.

The wheel bearings are of the ball type of the highest grade and, due to the fact that the universal joints can be drawn out through the full floating, mounting of the wheel are immensely over-size. Pivot bearings of a suitable size are provided, which renders steering easier than most pleasure cars.

Two separate brakes are provided—the one operated by the left foot being the emergency brake and that by the right foot the service brake. All brake rods are adjustable.

To operate the tractor the operator must be sitting in the seat with his left foot pressing the emergency brake pedal down. Every time his left foot is lifted from the brake pedal the brake is applied, bringing the machine to a stop and by means of a clutch on the controller shaft throwing the controller handle out of gear and the controller to neutral; it is then impossible to start the machine again without first releasing the emergency brake and bringing the controller handle back to neutral.

END CONTROL TYPE TRACTOR TRUCK

SENSITIVE BENCH DRILL

A new tool known as the "Dumore" Type A Drill is being put on the market by the Wisconsin Electric Company of Racine, Wisconsin. The machine is adapted for use by manufacturers and jewelers for light, sensitive work. The illustration shows the machine equipped with a direct connected variable speed type of motor, together with a No. 1 Jacob's chuck and a six-speed controlling

SENSITIVE BENCH DRILL

unit, affording speeds varying from 500 to 10,000 r.p.m. The controller is placed on the floor and is regulated by a foot pedal.

A wide range of operations may be conveniently handled with this drill, as it may be used with entire satisfaction on steel, cast iron, brass, aluminum, fibre, hard rubber, etc. The table is adjustable and gives the drill a stroke of ½ in. The capacity of the machine is for drilling holes up to 1-16 in. in diameter in steel and ⅛ in. diameter in soft alloys. Holes can be drilled to the center of a 5 in. circle. The motor and chuck are in perfect dynamic or running balance, thus assuring smoothness of operation and accurate results.

RAPID PRODUCTION LATHES

THE accompanying engraving shows a rapid production lathe now being built in 14 in. and 16 in. sizes by the Hamilton Machine Tool Co., Hamilton, Ohio. They are designed to meet the requirements of modern high-speed tool steel, and possess features imparting maximum power and accuracy for their size.

Accuracy and durability are sought through the use of an improved gear box, semi-steel bed with wide V box type headstock, chrome-nickel steel spindle and double apron with drop-forged gears. Friction has likewise been reduced to a minimum by the adoption of a central oiling system for the gear box and apron, sight-feed spindle oilers, and the use of bronze bushings for every running part.

The wide V on the bed is located well out in front so as to afford ample support to the tool carriage when working on large diameters. The design of the box head eliminates spring and vibration and causes the thrust to be taken by both front and rear bearings. Both sizes of lathe are regularly provided with single back gears and 4-step cone for 3-in. belt.

The hollow spindle runs in phosphor bronze boxes, scraped to a bearing and fitted with sight-feed oil cups. A special ball thrust bearing is located against the inside of the rear spindle box with take-up nut on outer end of spindle.

The extra heavy tailstock is secured by two clamping bolts, and has a plug binder for the spindle which is graduated in eighths of an inch. It is also provided with micrometer dial for fine adjustments.

An extra wide cross slide is fitted to the carriage. The latter has a bearing on the front and rear vees and also on the flat way in front. The compound rest is a semi-steel casting and is provided with taper gibs on both top and bottom slides. The chasing dial is set flush with top of carriage and can be disconnected when not in use to avoid wear.

All the shafts in the double box apron are hardened and ground, and the gears have the recognized safety arrangements. The length feed has an automatic knock-out and the apron hand-wheel is graduated in 64ths of an inch.

Forty-eight different threads and feeds are available with the regular set-ups of the quick change gear, while the open-end lead screw enables any thread to be readily obtained by the use of extra gears.

The principal dimensions are respectively: swing overshears, 16 in. and 18¼ in.; over compound rest, 9½ in. and 11¾ in.; length between centers on 6 ft. bed, 3 ft.; weight, skidded, 2,600 lbs. and 3,480 lbs.

FIRE PREVENTION TO REDUCE INSURANCE

AT the annual convention of the Canadian Manufacturers' Association held in Montreal last week, Sir John Willison pointed out that an enormous saving can be effected in the amount paid for fire insurance through a more concerted effort to reduce the fire hazard.

Canada will have to raise $230,000,000 more in revenue now than she has ever done before. One of the ways to make that possible is by eliminating the waste wherever that is possible. Greater care will reduce the fire risk and in that way the insurance companies can afford to give a lower rate.

We have been so wealthy in Canada in the past that we have been prodigal of our resources. We did not even stop to consider a few millions loss in fire each year. "Well, it is gone. Let it go. We have lots more where that came from." That has been largely the attitude. But we have come to the stage where every leak must be stopped up.

THE MACHINIST COMES INTO HIS OWN

A FEW short years ago when a boy reached the age when he had to choose his life's work or have it chosen for him, the tendency was to avoid, if possible, anything savouring too strongly of manual labor, especially if it were accompanied by dirty hands, greasy overalls and the restriction of personal liberty during the day such as obtains in machine shops.

Frequently, however, some hereditary bent for mechanics would overcome these minor objections and many a bright young fellow was considered by his friends to have sacrificed himself for some useless ideal. Not for them was the steady grind, the pride of production, the satisfaction of seeing in concrete form the result of personal effort and manual skill.

No occasion in the life of the clean clothes brigade can equal the moment when the apprentice cuts his first thread in the lathe and fits it to the nut. All the work of the so-called business man who works in an office would resolve itself into the most hopeless drudgery if deprived of the product of machinists' brains. The fountain pen is produced in quantities by the screw-machine—the typewriter owes its development—the press work—the dictaphone is a straight machine shop proposition—the rubber stamp depends on the toolmaker and die-sinker for its low price—the very stationery on which the clerk expends his energy is made by and printed with excellent examples of the machinists' art, yet the overalls do not occupy the same social status as the pen and ink manipulator.

Natural vanity may have something to do with it as the average boy may prefer to be one of the staff with the conspicuousness that arises from small numbers rather than become one of the crowd in the shop, and yet it seems almost a truism to state that except ye be submerged ye cannot rise to the top.

There are instances where successful men in certain walks of life started halfway up the ladder, but the names to conjure with, and they are constantly increasing, are those of men who covered the whole gamut, frequently from floor sweeper up. The longer the climb, the stronger must be the will and determination—the halfway start has made more failures than the long crawl.

The part played by the machine shop and engineering works at the present moment overshadows everything else with the possible exception of the chemical and mining engineer. Shipbuilding is simply applied engineering knowledge—engine building, scientific instrument work and allied lines are all based on similar principles, but the machine shop of a more or less refined type is necessary before these principles can be usefully applied, and the fate of civilization, triumph, or destruction is being decided by the machine shop.

The number of shells and guns, the quantity of equipment, the area of ground cultivated, the ships built and traffic handled, in fact, the actual existence of nations is initially dependent from hour to hour and week to week on the skill of the machinist, the art of the foundryman, and the ingenuity of the tool-designer and builder.

Stress of circumstances has forced many strangers into the payrolls of machine shops, and after the war the place thereof shall know many of them no more, but such of them as have tasted of the real knowledge of work and production, of utilizing the mysteries of science through the medium of mechanics, will be unwilling to become again mere hewers of wood and handlers of ideas. Their remaining in the industrial world will be to the advantage of the trade as well as themselves and their presence will be a helpful stimulant to all those who have looked forward to the day when the machinist would come into his own and overalls would become a garb of honor, not a dress of drudgery.

YOU CAN'T FOOL NATURE

MORE than ordinary interest attaches to the report that the claims of the Armenian inventor named Giragossian have not been substantiated before representatives of the Federal Government. Some time ago the inventor claimed that he had discovered a fuelless energy-producer which would supply all the energy needs of the world and after a scene took place in Congress, that body was sufficiently impressed to pass a bill providing for a test which has just been completed.

Five of the leading scientists of the United States were selected by Secretary Lane from a list of fifteen submitted by Mr. Giragossian and only they and the inventor were in the room during the test.

The entire proceedings from the start have been quite out of the ordinary and much criticism has arisen in the technical press regarding the probable success of what many claim to be a fake.

Nature is absolutely just and cannot be fooled into giving something for nothing. The law of action and reaction finds almost more explicit demonstration in energy production than in any other field of physical science, and it would be strange, indeed, if some revolutionary method of power generation has remained in obscurity all these years while many of the cleverest brains in creation have been passing over, under, and round about its hiding place, only to be brought to light by some hitherto unheard of individual.

RAILWAY officials report that 50,000 tons of steel products are rusting at Vancouver awaiting shipment to Russian consignees who have apparently forgotten their existence. We can see no right, moral or otherwise, by which Russia is now entitled to receive from Canada supplies in the category of munitions of war.

ALBERTA HAS TAKEN BIG COAL CONTRACT, AND DEPENDS ON ALIEN ENEMY LABOR TO FILL IT

Alberta Coal Men Have Uncertain Prop in Aliens, While Whole West Waits For the Coal to Keep Them Warm During the Coming Winter

A great deal of attention has been given to the coal question in Alberta. In fact there is a serious proposition at the present moment. The Alberta operators apparently went to Washington, and put it up to the government and fuel controller that Alberta could heat Western Canada, and it was nothing short of waste to put American anthracite in that corner of the Canadian market.

United States was anxious to have any help that would save coal and took the Alberta coal men at their word, telling them to go to it and fill up the bins of that section of Canada from Winnipeg to the coast.

Alberta has undertaken a tremendous task, and assumed tremendous responsibilities. If they fall down it's hard to say just what will happen.

It's not a pleasant thing to face a winter in Western Canada with an indifferent coal supply.

A writer who has travelled extensively in the West, speaking of Lethbridge and its alien miner problem, states:—

Where "If" Comes In

So the operators insist on qualifying their statement that they can supply all the excess fuel Eastern sections may require with the provision, "if we get all the labor we want, continuously for the year," resolves itself ultimately into the problem which is controlled by the men of alien enemy birth.

For instance, here is a verbatim report from two different mines in widely scattered sections of Alberta, made to the government which is just now trying to ascertain the nationality of each miner in District 18. This is from the Rosedale mine, submitted June 18—Austrian, 89; Canadian, 20; Italian, 11; American, 10; English, 6; Scotch, 5; German, 3; Belgian, 3; Dutch, 2; Swiss, 2; Welsh, 1. West Canadian Collieries, Greenhill mine—Canadian, 35; English, 12; Scotch, 5; Irish, 2; Welsh, 3; French, 7; Serbian, 17; Belgian, 28; American, 4; Russian, 7; Austrian. 45; Swedish, 5; Danish, 1; Norwegian, 3; Spanish, 1; Polish, 16; Bohemian, 17; Italian, 109; Slavok, 1. Of these 133 are citizens, natives and naturalized and 190 unnaturalized.

The Alien Enemy

In the analysis of these figures the government is trying to ascertain just now the actual hazard of the alien enemy holding up the production of coal in this crisis. The truth is that many mines and much property indirectly connected with the mining industry was owned outright by Teutonic individuals or companies when hostilities started. Some have managed to conceal their identity and their connections and others hurriedly transferred their interests, but the chief influence Austrians and Germans exert in these mines to-day is that they are relied upon to actually dig the coal. As John T. Sterling, inspector of mines for the province, asserted to the writer recently, "we could not mine twenty-five per cent. of the required supply this year without the active aid of the alien enemy miners. That's the reason we are forced to handle these miners with so much care."

But can human ingenuity invest this problem with an atmosphere that will enable the government to say specifically, "these alien enemies will work as required?" Every operator and laborer and business man and official with whom the writer has talked during two weeks of conscientious first hand investigation on the surface and in the mines forces the same answer—"no." It is a hazard and one the country must accept.

A. L. Smith's Plea

Here is a copy of a telegram that illuminates this alien enemy question. It was sent by Arthur L. Smith, of Calgary to Hon. A. L. Sifton at Ottawa, February 16, during the great strike crisis that threatened the whole mining industry: "I spent the day in the Rosedale camp. They have an efficient plant, pay high wages, excellent accommodation for men and have good board. Men in camp were quite contented, refusing to organize a union when solicited but were practically coerced by mobs from other mines composed largely of foreigners, sixty per cent. of whom are alien enemies. Troubles arose between the management and these outside alien enemies, subsequently all Rosedale miners went on strike tying up the whole field. I discussed matter with some of the miners who are anxious to go back but fear the union. Government must act shortly, either compelling management to accept the union or compelling men to work. If former, public sentiment, which runs high here on this alien enemy question, will be tremendously stirred; if latter, will be real step toward handling fuel situation. The problem in Alberta is very grave, affecting as it does the whole alien enemy question. Mounted police will corroborate all facts."

What Happened?

Smith is a prominent business man in Calgary and interpreted well the sentiment of the people on the alien enemy issues. The government acted very promptly through W. H. Armstrong, the federal administrator of the operators. He ordered the management to install the miners and specifically to re-employ an alien enemy named Vausman and to give him the identical team he was driving at the time of the strike—no other team!

Therefore the alien enemies triumphed and they at once got an exaggerated idea of their strength.

The docility of these alien enemies has not been improved by the events of recent date on the fighting fronts. They become more arrogant as they hear reports of German successes. This is one factor of genuine peril. But the whole fuel question is so complicated by selfish motives, business considerations, labor and transportation problems that it is baffling in its ramifications.

Making Big Money

Another Westerner, speaking of the alien labor problem in Western Canadian mines, says: "These men, by doing anything like a fair day's work, can make from $12 to $15 per day, and these excessive wages are tacked on to the consumer; $6.00 per day should be the limit these men should earn while our Canadian soldiers' wives, out of their meagre allowances, are trying to save enough to pay for their next winter's fuel. These alien miners are rolling in money at the present time and work when they think they will. Any mine manager will tell you that 80 per cent. of his troubles is due to the men."

One of the hard things to combat among the foreigners in the mines of Alberta, or British Columbia, is the fact that they do not speak our language. They are in many cases under the influence of a leader of their own whose one motive is to grab off every dollar in any way he can. Although much has been done to combat the practice, it has been in many a Western town, where a large amount of foreign labor was required, a common practice of these foreign leaders to accept the "palm money" of the poor foreigner to "get him a job," when all the time the job was there spoiling for some person to go and get busy on it.

The foreign problem in mining in Canada has always been a serious one—but just now with a winter coming on, and with a great stretch of territory, not quickly covered by transportation facilities, depending on these miners for their coal supply, it is not too much to call the situation critical and dangerous.

Troubles arose between the management and these outside alien enemies, subsequently all Rosedale miners went on strike tying up the whole field. I discussed matter with some of the miners who are anxious to go back but fear the union. Government must act shortly, either compelling management to accept the union or compelling men to work. If former, public sentiment, which runs high here on this alien enemy question, will be tremendously stirred; if latter, will be real step toward handling fuel situation. The problem in Alberta is very grave, affecting as it does the whole alien enemy question. Mounted police will corroborate all facts."

What Happened?

Smith is a prominent business man in Calgary and interpreted well the sentiment of the people on the alien enemy issues. The government acted very promptly through W. H. Armstrong, the federal administrator of the operators. He ordered the management to install the miners and specifically to re-employ an alien enemy named Vausman and to give him the identical team he was driving at the time of the strike—no other team!

Therefore the alien enemies triumphed and they at once got an exaggerated idea of their strength.

The docility of these alien enemies has not been improved by the events of recent date on the fighting fronts. They become more arrogant as they hear reports of German successes. This is one factor of genuine peril. But the whole fuel question is so complicated by selfish motives, business considerations, labor and transportation problems that it is baffling in its ramifications.

Making Big Money

Another Westerner, speaking of the alien labor problem in Western Canadian mines, says: "These men, by doing anything like a fair day's work, can make from $12 to $15 per day, and these excessive wages are tacked on to the consumer; $6.00 per day should be the limit these men should earn while our Canadian soldiers' wives, out of their meagre allowances, are trying to save enough to pay for their next winter's fuel. These alien miners are rolling in money at the present time and work when they think they will. Any mine manager will tell you that 80 per cent. of his troubles is due to the men."

One of the hard things to combat among the foreigners in the mines of Alberta, or British Columbia, is the fact that they do not speak our language. They are in many cases under the influence of a leader of their own whose one motive is to grab off every dollar in any way he can. Although much has been done to combat the practice, it has been in many a Western town, where a large amount of foreign labor was required, a common practice of these foreign leaders to accept the "palm money" of the poor foreigner to "get him a job," when all the time the job was there spoiling for some person to go and get busy on it.

The foreign problem in mining in Canada has always been a serious one—but just now with a winter coming on, and with a great stretch of territory, not quickly covered by transportation facilities, depending on these miners for their coal supply, it is not too much to call the situation critical and dangerous.

MARKET DEVELOPMENTS

War Contracts Are Being Placed for Very Long Terms--Some Run Until First of 1920

A Revival Noticed at Several Points in the Demand For War Purpose Machinery—Chains Are Up and Tendency is Still Higher—Many Ships Are Being Launched at Various Canadian Points

SHIPBUILDING can well be said to be attaining the summit of its growth in Canada. There is scarcely a week now that does not see a steel or wooden vessel taking to the water, and there are a large number of vessels under construction right now that will be ready to leave their berths in the next few months. The building of ships keeps up a steady demand for plate. In fact plate for this class of work seems to have the preference over anything else that is ordered from the mills in either Canada or the States.

Chains advanced quite sharply to the extent of $2 per hundred during the week, and the tendency is still higher. This is not stated to pave the way for a further increase, but there are market conditions that cannot be overlooked. Britain does not allow the hand-weld chain to be sent out any more, and there is in consequence a greater demand for the electric weld chain. The Emergency Fleet is also using a very large amount of this. Add to this the scarcity of raw materials passing to the chain plants and there is a situation that makes for higher values without much urging.

United States reckons apparently on a long period of warfare. At least it appears so from the contracts that have been placed for shells. The method of giving them out in renewals that are good for two months or so at capacity is not adhered to any longer. Some of the orders are for a year, others for a longer period, while two at least are known to guarantee shop capacity until the beginning of 1920.

There is a need still for men in many shops. Against this, however, it is reported from several centres that the labor problem is quite normal, and that little trouble is experienced in securing all the hands necessary.

Pig iron and good scrap material are scarce at either United States or Canadian points. The tendency to use large amounts of scrap at times brings trouble with a poor casting in foundry work, as the analysis of the scrap was not definitely known. United States War Board is just now taking steps to relieve this situation by having a survey made, nation wide, to secure reports on all material that could be scrapped to provide the necessary supply for the open hearth furnaces.

SHIPBUILDING ATTAINS ZENITH OF ACTIVITY—LAUNCHINGS NUMEROUS

Special to CANADIAN MACHINERY

MONTREAL, July 3.—The holiday season resulted in a quieter tone in the general situation, but actual production has as yet not been materially affected. Local interest is still centered in the renewal of the activity that has followed the placing of further orders for shrapnel shells, and this, together with the large contracts that have been let for American business, has been a wonderful factor in reviving an enterprise that showed a tendency to wane during the early part of the present year. In consequence of recent developments the requirements for machine tools has greatly increased, and the demands for accessory shop equipment have been exceedingly heavy. Both steel and wooden shipbuilding have attained the zenith of activity and launchings are now almost a weekly feature.

Steel More Settled

No marked change has been noted in the general steel situation and trading continues on virtually the same basis of that of the past several weeks. Dealers here are getting inquiries for steel that they are unable to fill owing to the regulation under which they are compelled to carry on business. The market is beginning to take on a more settled appearance as the trade realize that the present fixed prices on finished steel will remain unchanged. With all major operations practically under the control of the government approved bodies the recognized market is a thing of the past, and the sellers in many cases have become the buyers.

Plate requirements are on a par with those of shell steel, and mills are working to capacity to supply the ever-increasing demand. This has been emphasized recently in the States where the shipbuilding has been augumented by fabrication of steel at points apart from the erection site. While dealers here are contemplating a revision of their prices of certain materials they report no change over last week. The effect of the American advance in freight rates is not yet definitely known so that in some respect the situation here is unsettled.

Metal

The general metal situation has improved and the various markets have taken on a firmer tendency but price advances have not been marked. It was thought that the advance in freight rates would be a factor in the movement to higher levels of some of the metals, but the action of the American government in respect to steel prices has had the effect of steadying the markets, but notwithstanding the undertone is stronger on certain metals. Copper is steady but some nervousness is retained.

Tin is still a problem under the pronounced uncertainty. Spelter is firmer and may go higher. Lead is strong but quieter. Antimony and aluminum are steady and firm, the former with an undertone of strength over the increased demand for shrapnel.

Copper.—The situation is featureless

and operations are proceeding on a steady basis. Agitation is still evident in respect to a higher fixed price, but with the present figure ratified until the middle of August it is unlikely that even the argument of the higher freight rates will result in an early revision, and even when the present period expires the possibilities appear strong for a still further extension of the price now effective. Dealers here report unchanged conditions with the demand about normal, slight increase being noted for castings of copper. Prices remain firm at 29 and 30 cents per pound.

Tin.—Scarcity of visible tin has added renewed tension to the situation and offerings are not as free as the previous week. Little spot metal is available and sales are being made only on a future basis. New York nominal prices have taken on a firmer tone following the advance on the London market. Future positions are harder to obtain. Dealers here while anticipating no immediate advance are looking for continued firmness. Last week's quotation of $1.25 is still asked by most of the dealers.

Spelter.—The local situation has taken on a stronger tone as a result of the developments in the States where the market is considerably stronger. The consuming demand is little above normal but the supply has been reduced as the result of labor unrest at certain of the mines, this affecting the output of some of the American smelters. Dealers here are looking forward to a stronger market but present prices are on a par with those of last week.

Lead.—A comparative calm has apparently settled on the market as the active buying of the past week has been followed by a reluctant tendency on the part of consumers to cover future requirements. A steady demand is maintained on the local market but the price asked remains unchanged.

Machine Tools and Supplies

Machine tool activity is pronounced at the present time owing to the heavy dedand for shell making purposes. The renewal of shrapnel orders, after considerable of the old equipment has been diverted to the making of the American shells, has necessitated the replacement of many tools by those who are now working on the 18-pounders. The abnormal conditions that prevail in the States make it very difficult to obtain equipment from American builders so that the Canadian tool builders have been required to stimulate their output. Dealers here who have been unable to obtain required delivery of new equipment are acquiring all available used machinery suitable for their shell customers. The demand for ship working machinery has declined in volume but the requirements for small tools and supplies are as great as ever. Dealers report a heavy demand for all classes of small supplies and tools for shell production, and where these have to be brought in from the States the uncertain delivery is often very annoying.

Scrap Without Feature

Trading in scrap and old materials is continued in a quiet manner with nothing of interest to report. Conditions of handling the metal has changed greatly during the past year so that the dealers are not the factor they formerly were. Much of the dealing is now done direct from the producer to the consumer and in this way the dealer has practically been eliminated. Considerable busine- is still done in old machinery scrap for grey iron foundries, and the transactions in old metals are still carried on in fair volume. The present market, however, is one of firmness with quotations holding to the high level.

POINTS IN WEEK'S MARKETING NOTES

Launchings of ships, both steel and wood, are becoming matters of frequent occurrence in Canada, and the industry is reaching the summit of its capacity.

—

Most of the Ontario cities report that there is a fair supply of labor now. Some of the smaller centres find that it is hard to get and retain the more highly skilled men.

—

The agitation is still going strong in some centres for an increase in the price of copper, which is now fixed by the United States Government at 23½c per pound.

—

Some munition contracts placed in Canada recently have a stability to them that was unknown before. One of these orders will run a shop at 800 per day up to January 1, 1920.

—

American pig iron producers express satisfaction at the way the War Board is handling affairs. The pig iron men discussed many plans to make production greater and keep down costs.

—

Cool weather of the past fortnight has helped blast furnace operations to shove up production records.

—

There is a decided shortage of good scrap at United States points, especially anything in the line of good heavy melting steel.

—

A campaign is being carried on in United States to secure reports on all sources of available scrap in the country.

SHARP ADVANCE IN ALL SIZES OF CHAIN

And the Tendency of the Market is to Move to Still Higher Figure

TORONTO.—There is still one word that describes the busy state of trade in the machine tool, supplies and equipment business here, and that is "munitions." Dealers are up to their necks in business in many cases. Each plant that gets orders for new business wants to get production started as soon as possible, as the element of urgency and haste on the western front is transmitted in a large degree to the business passing here. Some contractors from this district are still visiting American points in connection with the securing of equipment. Canadian dealers have a very large volume of business just now, and they are working at considerable tension to cope with the situation.

The Upward Tendency

It was stated in these columns a week ago that there would soon be an upward revision of the schedule at which chains were being traded. It has taken place and the increase amounts to two cents a pound on all grades, either B, BB or BBB. There are some 185 varieties of chain made and sold on the market. In fact it is a business all by itself. The American industry has a very strong influence on the Canadian market both in regard to supply and price. Immense lengths of chain are being called for at the present moment for use in the emergency fleet, and there is the added element of excessive haste in the matter. The British government will not allow the export of the hand-made variety, for which there used to be such a demand. In fact there was a time when all the navies of the world specified British hand made chain on account of the purity of the iron used in them. Even the German navy used the British chain. There has been a big inroad made on this trade in recent years by the machine-welded product, makers of the latter claiming that there is a uniformity of strength that cannot be placed in a hand-made chain. Big quantities of hand-made chain were replaced by the machine-made variety in work on the Welland Canal, when it was found that the former was not standing up under the heavy strain in dredge work, e- Inch chain is quoted to-day at 14½c per pound against last week's price of 12¼c. and the dealer who sells it claims that he is not making as much as when it was listed at the lesser price as he cannot pass the increase in the entirety on to the consumer. In addition to the big demand the makers in the States claim that preference now goes to plate mills, and in consequence they are short of material. The tendency is for a higher price in chains, and this is likely to become more noticeable in the very near future.

Scrap Metals

There has been a fair volume of business passing in the second hand metal trade during the week, but there is absolutely nothing in the form of a feature in the whole situation. The situation in the American market is quite similar to that here at present. Steps are being taken now to have a survey taken of the scrap situation across the line, and circulars are being mailed to dealers inquiring the amount of stock on hand now and the amount they had a year ago. The inquiries also take in all lots of unprepared scrap that are being withheld from the market, principally in the form of obsolete railways, old mine heads and tipples which are not being operated, unused bridges or similar structures, old manufacturing plants not in operation—in fact any material which can be shipped to the scrap yard for preparation.

In Canada reports are sent out by dealers each month showing the amount of scrap coming into the yard and the amount sent out..

It may yet be found necessary to comb out the country to increase the amount of melting scrap coming into the market.

The high price of tin does not bring in any in the way of scrap. Tin stands very low in the amount of it that is recovered—in fact its principal use in that form is for the purpose of alloys.

There are no changes in prices being paid by dealers for scrap metals this week.

Non-Ferrous Metals

Canadian dealers are not much inclined to the belief that there will be a higher price set for copper in United States. The suggestion has been made that there will be two prices—one for the large producer and another or higher for the small mine. Early suggestions were that companies whose cost was above a certain figure should receive a premium over the lower cost properties. Now it appears that instead of having the cost the determining factor there is a possibility that companies turning out 10,000,000 pounds of copper or less each year will receive preferential treatment over the larger mines. The reason for such a course is not readily apparent, and it is hardly likely to come to pass.

Tin may yet reach higher levels, at least that is the latest word from New York markets. Price advances do not seem to have the effect of increasing the amount coming on the market. The only supposition is that there is none to be brought out.

MANY LARGE ORDERS STILL BEING PLACED

War Demands Are Still Reaching Ahead and Run Into Immense Sums

Special to CANADIAN MACHINERY

NEW YORK, July 3.—Shipbuilders, ordnance manufacturers, aircraft builders and a host of other industries engaged in war work, are constantly in the market for machinery, and many small orders have been placed during the past week.

Aside from the Bethlehem Shipbuilding Corporation, which is still buying machine tools and cranes heavily, most of the orders closed are of a miscellaneous character, but some large inquiries are coming from gun and shell manufacturers. The Watertown Arsenal wants a large number of machines for its motor carriage department for the manufacture of mobile gun carriages, and Bullard Engineering Works, Bridgeport, is buying additional equipment for its gun shop.

The Symington Machine Corporation has purchased equipment in the East for its large shell plant at Chicago, while the American Steel & Machinery Co., Pullman, Ill., has purchased the machinery necessary for its projectile factory in the Central West through the American Clay Machinery Co., Bucyrus, Ohio, which is the parent organization. The Wright-Martin Aircraft Corporation is preparing to purchase $1,500,000 worth of tools for its Long Island City plant, which will be equipped to produce fifty motors a day.

Crane manufacturers are receiving numerous small orders from shipyards, steel works, copper producers, electrical equipment manufacturers and from makers of pumps and war munitions. The New York Shipbuilding Corporation has issued a supplementary list for fourteen cranes, the American Car & Foundry Co. has closed for six cranes, and the Vulcan Iron Works, Wilkesbarre, Pa., has bought eight cranes. The General Electric Co. has ordered cranes for its West Lynn, Mass., and for its Schenectady, N.Y., plants. Among copper producers the Braden Co. has purchased conveying machinery, the Nichols Co. is taking bids on cranes, as is also the Michigan Copper & Brass Co. of Detroit.

The Carolina Shipbuilding Corporation has closed for $400,000 worth of machinery, some of which is already boxed ready for shipment to Wilmington, where fabrication of the steel for the fore-and-aft portions of twelve large steel ships of the Isherwood type will be built by the Government. The Emergency Fleet Corporation has just ordered 36,000 tons of steel for these ships, 15,000 tons of which will be shipped to Roanoke, Va., where the Virginia Bridge Co. will fabricate the plates and shapes for the midships and the remainder of the tonnage will go direct to Wilmington. The steel is to be delivered in thirty days, and the first keel will be laid in August. The Federal Shipbuilding Co. will build two additional ways at Kearney, making twelve in all. Additional launchings at this yard will take place speedily, and it is expected that twenty boats will be launched and that ten will be fully equipped and ready for sea service this year.

More Orders

Among the other manufacturers who have placed orders for machinery recently are the Worthington Pump & Machinery Corporation, which has bought tools for its Buffalo plant; the United States Cast Iron & Pipe Foundry Co. has bought cranes for its Scottdale, Pa., works, and the International Arms & Fuse Corporation, Bloomfield, N.J., which has bought machine tools. Railroads are still buying moderately; the Pennsylvania has revised its recent inquiry for cranes.

Government orders for approximately 250,000 tons of finished steel have been distributed by the War Industries Board, nearly half of which is for car construction. The Carnegie Steel Co. will furnish 50,000 tons of structural shapes and 40,000 tons of bars to the Pressed Steel and Standard Steel Car Companies. Sheet manufacturers have received orders for 15,000 tons of sheets for car construction and 60,000 tons of blue annealed and black sheets for export to France. Orders for about 20,000 tons of plain and barbed wire have also been distributed for shipment to France over the third quarter of the year. Independent plate manufacturers have received additional orders for 30,000 tons of sheared plates for ship work. The Railroad Ad-

LITTLE CEREMONY IN TAKING MEN IN U. S. FOR THE FORCES

"They are not standing on much ceremony in connection with the drafting of men for the army in some of the United States points," remarked a Canadian, whose business relations cause him to make frequent trips across the border, "nor does it seem to make a very great deal of difference what a man is working at.

"I happened to be in a shop in Bay City a few days ago," he remarked, "and while I was in conversation with the manager of the place the police van pulled up before the factory. Three or four officers went in and in short time came out with four young men. I was informed that this was not the first time it had happened. The men taken off by the police had probably not reported for the draft in which they were called. This shop was working on war orders, too, but not in a direct way."

The Canadian went on to explain that in many cases the shop that is doing work on a sub-contract is not getting war preference in the same way as it is being shown to the first contractor. In the instance to which he referred the shop was working on chucks, these to be supplied to a firm that was making war purpose machinery.

He was also impressed with the number of men there seemed to be in several of the United States points that he called at during the week. The labor situation in many of the points there is not nearly as acute as it is on this side of the line, owing to the much larger population, and the smaller proportion of it that has donned the uniform.

Determining the Efficiency of Gear Drives*

Alden Absorption Dynamotor Used With Motor Suspended in Cradle—Both Field and Armature Free to Move—Results of Tests on Bevel Gears and Worm Drives Given in Charts

by C. M. Allen and F. W. Roys

APPARATUS for determining the efficiency of gears and other drives has recently been developed and used for making tests in the Mechanical Engineering Laboratories of the Worcester Polytechnic Institute. The fundamental principle of the apparatus consists in the direct measurement of the loss of power in the gear drive instead of the usual method of determining the input and output and subtracting one from the other.

2. Since the efficiency of good geared drives is relatively high, the input and output are very nearly equal, and any small errors in the measurement of these relatively large quantities will make a very large per cent. error in the difference, which is the power loss.

3. It is, therefore, evident that a method by which the loss may be measured directly and independently of the input and output would be very much more accurate.

Theory of Apparatus Used in the Tests

4. The theory of the apparatus which was used in the tests is as follows:—An electric motor is so hung in a cradle that both its armature and field are free to turn. The armature shaft is connected directly to the pinion gear shaft and the driven shaft directly to an Alden absorption dynamometer. The reaction of the motor field is balanced by the action of the absorption dynamometer through by a simple lever. The arms of the lever are accurately proportioned to the ratio of the gears.

5. The general idea of the apparatus is as follows:—An electric induction motor is hung in a cradle on double roller bearings, and an arm attached to the motor casing makes a cradle dynamometer. The motor shaft is connected directly to the drive shaft and an Alden dynamometer is put on the driven shaft. These dynamometers are so arranged that the force exerted by the end of the arms is downward. The arms of the dynamometers' are of equal length and at the end of each is a fixed knife edge. A lever with three knife edges mounted upon it has the two outer knife edges adjusted so that the distance between them is equal to the distance (horizontal) between the dynamometer knife edges. The third knife edge divides this distance into segments whose ratio to each other is the same as the gear ratio. These three knife edges lie in the same straight line. The lever is now placed directly over the line between the dynamometer knife edges, and is supported by the third knife edge which rests on platform scales. The end knife edges of the lever are connected to the dynamometers in such a way that the high-speed dynamometer is connected to the long arm of the lever. A counterweight and a rider weight are mounted upon the lever. See Fig. 1.

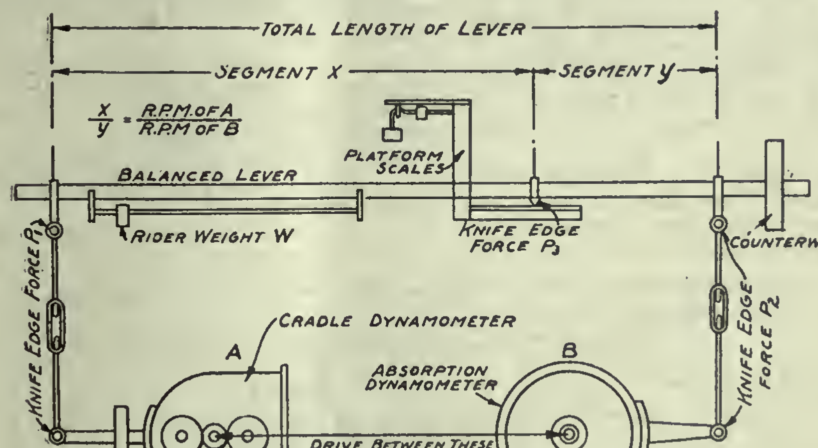

FIG. 1—APPARATUS USED IN MAKING TESTS.

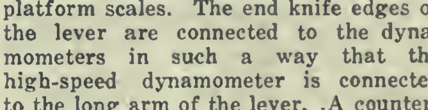

FIG. 2—DIMENSIONED SKETCH OF APPARATUS

Method of Testing

6. The method of testing, so far as the operation of the lever system is concerned, is identical for all tests, and therefore the explanation of its action is made perfectly general.

7. The centre of gravity of the Alden brake was very nearly in the horizontal plane, so that a slight movement of the arm did not measurably affect its balance. The cradle dynamometer was so loaded that its centre of gravity was only a short distance below the shaft centre, and a load of 2 lb. at the end of the arm was enough to entirely upset its equilibrium. The lever was then placed in position as described above and statically balanced by means of the counterweight shown in Fig. 1. A long pointer attached to the lever showed the

*Paper read before the spring meeting of the American Society of Mechanical Engineers.

position of the system relatively to the initial condition of balance.

8. When the rider weight W was in its initial position, the load P_3 (see Fig. 1) was noted as the initial reading of the platform scales.

9. The variables entering into the balance of this apparatus are then the forces P_1, P_2 and P_3, and the displacement of the rider weight. P_3 may be measured at any time while the apparatus is in operation and so may the displacement of the rider weight.

10. It should be noted here that the amount of P_3 has nothing to do with the calculation of the power loss, which is found as follows:

Method of Measuring Power Loss

11. It will be seen from the preceding description and from Fig. 1 that $P_1x = P_2y$ for 100 per cent. efficiency; but since the efficiency is never 100 per cent., P_1x must exceed P_2y by the amount necessary to overcome the loss in moment. This difference immediately upsets the balance of the lever, of course, but equilibrium may again be restored by shifting the position of the rider weight in the proper direction. This displacement of the rider weight is therefore a measurement of the change of moment, and when corrected for the speed of the apparatus it is a measurement of the power loss.

12. Here the input power is automatically balanced against the output and any little change in the latter is immediately taken care of by the motor, and it is impossible for the apparatus to be out of balance except by the amount of the transmission loss. This is the feature of the method which distinguishes it from all others.

13. The power transmitted by the drive may be computed by noting the change in the load P_3 on the platform scales, and such computations will be shown later.

14. In operation it was found necessary to start the apparatus and let it run for several minutes before taking note of the initial position of the lever. The zero reading was frequently checked during the period of testing.

Efficiency Test of Bevel-Gear Drive

15. Data of Gears and Apparatus. The gears were 5 per cent. nickel steel, case-hardened, 5 pitch, 1½-in. face. They were cut by the Brown & Sharpe Mfg. Co. and were mounted by them on ball bearings especially designed for testing purposes. Following are the preliminary data employed:

Number of teeth in gear, 52.
Number of teeth in pinion, 14.
Ratio, $52 \div 14 = 3.714$.
Total length of lever between outside knife edges (see Fig. 3), 3.95 ft.
Length of long arm of lever, 3.112 ft. = 37.344 in.
Length of short arm of lever, 0.838 ft. = 10.056 in.
Length of dynamometer arms, 31.5 in.

A force of 2 lb. at 31.5 is equivalent to 1 h.p. at 1,000 r.p.m., for which the expression 1 hp_{1000} will be used.

16. Calculation of Horsepower Loss from Movement of Rider. Referring to Fig. 3, a force of 2 lb. at $P_1 = 1$ hp_{1000}. Therefore 2×37.344 = inch-pounds of moment in lever necessary for 1 hp_{1000}, and if the rider weight is 3 lb., then for this to balance 1 hp_{1000}, 3x must equal 2×37.344, whence $x = 24.893$, and therefore a movement of 24.893 in. of the rider is equivalent to 1 hp_{1000} for a 3-lb. rider.

17. If the rider weighs but 1½ lb., then the same displacement means only ½ hp_{1000}. A paper scale was made according to these figures and was fastened to the lever. The readings for hp. loss were taken from it throughout the test.

18. Calculation for Horsepower Input. Referring to Fig. 2, since the initial load of P_3 was taken with the rider weight W already on the lever, a change in the position of W does not change P_3, but merely changes the moment. Therefore, in moment equations of the lever, regardless of where the centre of moments is taken, the arm of the moment of W is always the distance from the zero position.

19. The force P_1 is a measure of the input power if the speed is known, and it is merely necessary to calculate this value in order to solve the problem. Considering the moment equation of the lever, we have

$$0.838\ P_3 - 3.95\ P_1 + Wx = 0$$

whence

$$P_1 = 0.838\ P_3 + Wx \div 3.95$$

If $W = 3$ lb.,

$$P_1 = 0.2122\ P_3 + 0.759\ x$$

if $W = 1.5$ lb.,

$$P_1 = 0.2122\ P_3 + 0.379\ x$$

x being the displacement of W measured in feet.

20. Referring to Table 1, for accuracy of recorded data the values in column 5 (x ft.) and column 10 (rider hp_{1000}) should vary together since they both refer to the displacement.

21. Column 10 is recorded for one purpose and read from the paper scale directly in hp_{1000}, while column 5 is recorded for another purpose and the measurement is recorded in feet measured by an ordinary rule.

22. It is necessary to read the values recorded in column 10 with as great accuracy as possible, but the approximate distance to the mean position as determined in column 10 is as close as it is necessary to record the values of column 5.

23. The values in column 10 after correction for speed give the total loss in

1200	½	20	4.245	0.50	0.189	4.434	2.217	2.67	0.120	0.144	2.526	91.6

power and become therefore the whole of the numerator of the equation for loss of efficiency, namely,

$$\text{Loss of efficiency} = \frac{\text{Hp. loss}}{\text{Hp. input}}$$

These values for hp. loss are recorded to three significant figures, but the third is somewhat in doubt, and therefore the absolute accuracy is only through two significant figures.

24. In figuring hp. input it is necessary to use the value P_1, which is obtained by means of the equation $P_1 = 0.2122P_3 + 0.759x$, where x is the value in column 5. The maximum variation in feet from the mean position (column 10) is less than 0.1 ft., but suppose that it was 0.1 ft.; then column 5 might have been 1.8 instead of 1.7 as in the first recorded line.

25. To see what the effect of such a discrepancy would be, the following computations have been made, taking x=1.8 and x=1.7, respectively:

$$P_1 = 200 \quad 0.2122\ P_3 = 42.44$$
$$P_1 = 42.44 + 0.759\,x$$
$$= 42.44 + (0.759 \times 1.8) \text{ or}$$
$$= 42.44 + (0.759 \times 1.7)$$
$$= 42.44 + 1.36 \text{ or} = 42.44 + 1.29$$
$$= 43.80 \text{ or } 43.75.$$

26 As hp_{1000} input $= \frac{1}{2}P_1$ then hp_{1000} equals either 21.90 or 21.865, and

$$\frac{\text{Hp. loss}}{\text{Hp. input}} = \frac{\text{Rider } hp_{1000}}{\text{Input } hp_{1000}}$$

whence

$$\text{Loss of efficiency} = \frac{0.746}{21.90} \text{ or } \frac{0.746}{21.855}.$$

27. It is thus seen that, measuring as accurately as possible, the numerator is only accurate to the second place, the third being in doubt; and that the second place in the denominator is sure and the third fairly sure, although considered in doubt. Therefore the denominator is as accurate as the numerator.

28. The numerator is as accurate as the apparatus will allow data to be read, and therefore the inaccuracy of the data of column 5 has no effect on the final accuracy of the work.

29. In Test No. 1, the data of which are given in Table 1, practically no lubrication was used, the gears having been washed off with gasoline. Previous to this there had been oil and graphite on the gears and some of the graphite still remained on the teeth. However, after running for a while they were practically non-lubricated. The 3-lb. rider had to be used in this case because of the amount of the friction loss, which, by the way, was sufficient to cause the gears to heat considerably.

30. Table 1 gives only a few of the results actually obtained, for the apparatus was started time after time and the balance by the rider gave the same results over and over again.

31. The next test was made to see how much the efficiency would be increased with good lubrication. Accordingly some heavy oil and flaked graphite were mixed and used as a lubricant. The efficiency was so much increased that the 1½-lb. rider weight was sufficient, and again it was found that the same results were obtained time after time. The recorded data appear in Table 2.

32. Later, after the graphite and oil had become more perfectly blended, another test was made, the recorded data for which are given in Table 3.

33. The efficiency curves for these three tests are all given in Fig. 4. The difference between the results of non-lubricated and lubricated conditions is perfectly clear. The test with the more perfect blending of the lubricant showed results identical with the previous one except as indicated by the dash line at the end of the upper curve. This showed that the lubricant was not squeezed out from between the teeth at quite so low a pressure.

34. The form of the curves and the consistency of the readings convinced the experimenters that very reliable results had been obtained.

Efficiency of Worm-Gear Drive

35. Data of Gear, Worm and Apparatus. The gear was made of phosphor bronze with 40 teeth; pitch diameter, 10.5704 in.; throat diameter, 10.9964 in.; circular pitch, 0.8302 in.; angle of teeth with axis, 38° 16′ 5″; normal circular pitch, 0.6518 in.; thickness of tooth, 0.3568 in.

36. The worm was made of Aurora steel, case-hardened, and had 9 teeth; pitch diameter, 3.015 in.; outside diameter, 3.441 in.; circular pitch, 1.0524 in.; angle of teeth with axis, 51° 43′ 55″; thickness of tooth, 0.295 in.; lead, 7.4719 in.

37. This drive was made by the Brown & Sharpe Mfg. Co., and mounted by them in a ball-bearing case especially designed for the purpose of testing. The set-up of the apparatus was the same as for the bevel-gear tests (see Fig. 2), except that the positions of the knife edges on the lever were changed to agree with the new gear ratio, giving the following dimensions:

Number of teeth in gear 40
Number of teeth in worm 9
Ratio, 40÷9 .... 4.444
Total length of lever between outside knife edges .... 3.645 ft.
Length of long arm of lever .... 2.9755 ft.=35.72 in.
Length of short arm of lever .... 0.6695 ft=8.04 in.
Length of dynamometer arms .... 31.5 in.

38. Calculation of Horsepower Loss from Movement of Rider. The calculation for horsepower loss in this case is

1177	2	80	16.97	0.50	0.189	12.159	8.579	10.08	0.12	0.141	9.939	98.4
1195	1	40	8.49	0.50	0.189	8.679	4.339	5.19	0.12	0.143	5.057	97.4
1200	½	20	4.246	0.50	0.189	4.434	2.217	2.67	0.12	0.144	2.526	94.6

the same as for the bevel-gear test except for the change in length of the lever arm and the weight of the rider. In this test a 6-lb. rider was used and the equation is as follows:

$$6x = 2 \times 35.72$$

from which

$$x = 11.91$$

therefore a movement of 11.91 in. of the rider is equivalent to 1 hp_{1200} for a 6-lb. rider. A paper scale laid out according to these figures was used throughout this test.

39. Calculation for Horsepower Input. The equations are of the same form as those for the bevel-gear test and the figures are as follows:

$$0.6695P_2 - 3.645P_1 - Wx = 0$$

and for W=6,

$$P_1 = 0.1837P_2 - 1.647x$$

x being the displacement of W measured in feet.

40. Considerable trouble was experienced at first in getting the initial balance of the apparatus as it was not at all sensitive. However, it was soon found that the weight of the Alden dynamometer caused a deflection of the shaft and consequently friction on the oil-retaining ring of the gear case, which had a very small clearance. When the weight of the dynamometer was taken from the shaft by means of a cord passed around the hub and an equalizing bar above, to

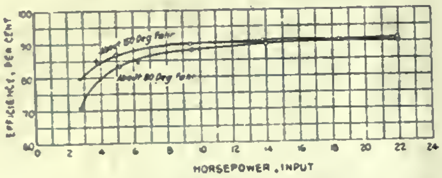

FIG. 4—HORSEPOWER-EFFICIENCY CURVES OF WORM GEAR DRIVE

Results at two different temperatures of lubricating bath. Ratio 40 to 9; rev. per min. of worm about 1,200.

which the ends of the cord were attached, the apparatus became sensitive at once. The purpose of the equalizing bar was to lift the weight without introducing any moment for slight movements of the dynamometer casing.

41. This apparatus ran without anywhere near as much vibration as the bevel-gear apparatus and it was accordingly easier to handle.

42. A heavy oil sold by the Texas company under the name of Thuban oil was used for lubrication. The power loss in these gears was so large, however, that the temperature of the oil bath increased very rapidly. No tests were run to determine the limit of this rise or rate of increase, but tests were made at certain selected temperatures. Data of these tests are given in Table 4.

43. By testing at constant temperature the effect of the change in viscosity of the oil on the action of the lever was eliminated, but the effect on the efficiency is clearly shown by the curves in Fig. 4.

44. It is of course obvious that no test could actually be made at constant temperature, and the tests were really made by keeping the load constant and noting the loss as the temperature went up. These readings were recorded, however, as if the tests had been constant-temperature tests.

45. It is interesting to note in Fig. 4 that at the lowed temperature, when the oil was viscous, the efficiency at light load was quite low, while at the higher temperature the efficiency increased, as one would expect, on account of its taking less power to churn up the thinner oil. But at the other end of the curves, that is, the high-power end, the reverse condition is found, indicating the inability of the oil to maintain proper lubrication at high tooth pressures when it becomes thin.

46. Again the form of the curves and the consistency of the data obtained point to the reliability of the apparatus.

47. It is accordingly concluded that this apparatus will measure accurately the efficiency of any positive shaft drive where both shafts are rotating at constant speed, and that it seems to be the best method yet devised for testing gear drives for efficiency, since it measures directly the actual power loss.

48. While this paper has described only tests of bevel-and worm-gear drives, tests of other drives have been made, and the method is applicable to all types.

TESTING GUNS FOR AIRCRAFT

The Browning machine gun has successfully undergone a test to determine its value for use with aircraft. This is one of three types of machine guns with which the rate of fire can be so synchronized with the revolutions of the propeller of a tractor airplane that the gun can be fired by the pilot of a combat plane through the revolving blades. Firing in that fashion, it is necessary to aim the machine gun by steering the plane directly at the target. The direction of the plane gives direction to the fire and the pilot can fire the machine gun while controlling the plane.

Connected With Engine

Airplane propellers revolve at from 800 to 2,000 revolutions per minute. The machine gun is connected with the air plane engine by a mechanical or hydraulic device, and impulses from the crank shaft are transmitted to the machine gun. The rate of fire of the machine gun is constant and its fire is synchronized with the revolving propeller blades by "wasting" a certain percentage of the impulses it receives from the airplane engine and by having the remaining impulses trip or pull the trigger so that the gun fires just at the fraction of the second when the propeller blades are clear of the line of fire.

The pilot operates the gun by means of a lever which controls the circuit and allows the impulses to trip the trigger.

Severe Test Given Gun

The test given the Browning gun was severe. A gun was mounted on the frame of an American combat plane and connected with the airplane engine. The test was conducted on the ground and in place of the propeller a metal disk was attached to the crank shaft. The Browning gun was then required to register hits on the metal disk as it revolved at varying speeds from 400 to 2,000 revolutions per minute. The slightest "hang fire" or delay in action on the part of the gun would have been shown by the failure of the bullets to hit precisely on the spot on the disk representing the centre of the zone of fire. The gun functioned perfectly.

The Browning gun to be used with aircraft is the heavy type with the water jacket removed.

Will Also Use Marlin Gun

Besides the Browning, the United States will also employ the Marlin aircraft gun as a synchronized weapon. Several thousand of these have been manufactured and the gun is in quantity production.

The British and French use the Vickers as a synchronized machine gun.

The Lewis aircraft machine gun is used by the British, French, and American forces, but for a different purpose. In a two-seated combat plane, fixed machine guns are mounted forward to be operated by the pilot and flexible guns are mounted to be operated by the observer in the rear seat of the plane. The observer operates Lewis guns on flexible mounts, firing to right or left of the plane.

It is of vital importance to have absolute reliability of function in a synchronized machine gun on tractor airplanes.

Producing Special Steel to Suit Specific Purposes

New Strip Mill at Massillon, Ohio, Adapts Steel to Methods and Machines—Produces Rolled Strips With Wide Range of Uses in Standard and Alloy Steels—Designed to Eliminate Manufacturers' Troubles

FOR years it has been to a great extent customary and quite necessary for manufacturers of machines and parts to consider what material wat available in the market and then adapt their work and product to that condition. This has sometimes placed them at great disadvantage and has been a check to extensive improvements and development.

Within the last few years the use of alloys in steel making has passed beyond the experimental stag into standard use and practice. It has been the means of establishing new industries and developing new machinery and new method. In one product the evolution has promoted a plant totally different to any heretofore devised. It is the installation at Massillon, Ohio, of the plant of the National Pressed Steel Company, which was specially designed and built for rolling strips by an improved method and practice for a wider range of uses in standard and alloy steels.

Organized Effort

Realizing the needs of the situation a group of young men familiar with the difficulties incident to the deep drawing, stamping, forming and pressing of steel products, and also the need for new and better qualities, set out to build a mill to meet the demands. Their aim was to produce a wider range of sizes and the proper quality and physical characteristics in hot and cold rolled strips especially adapted to this particular class of work.

Representative lots of steel intended for stamping and similar purposes were carefully examined by microscope analysis and other methods, all of which indicated the fact that while in the past research work had been carried on to improve the composition of steels in general, and that while some attention had been given to scale elimination, etc., very little thought had been given to the subject of mechanical treatment. This investigation and careful research convinced the designers that new methods and practice were necessary.

All the information and data obtained pointed to the necessity for a departure from standard machinery, methods and practice. Before designing the machinery, equipment and plant, which for the new purposes required many innovations in heating and rolling, it was considered necessary to consult the trade purchasing and using this class of steel in order to obtain complete data and authentic information.

Survey of Requirements

An abstract was accordingly prepared containing thirty-seven questions, each one important to the establishment of the new methods thought necessary, and so prepared as to require little time and effort in giving the answers. This was sent to a large number of manufacturers producing pressed and drawn steel specialties, and brought forth immediate and enthusiastic response. The returns reached forty-seven per cent., which answered in whole or in part the entire abstract.

With the complete data and reliable information then at hand bearing on size, finish, analysis, quality, physical characteristics, the design of this unusual plant was undertaken by the company's own men, carefully adhering to basic principles. In spite of adverse conditions in material and machinery markets, weather, etc., in ten months and one day from the time ground was broken the plant was in operation.

This plant with its special equipment, new methods and practice is now producing a material of such physical property and quality that without any annealing it can be used in a great many cases where formerly annealed strips were considered a necessity.

Inspection of Raw Material

Raw material is received in the form of slabs and billets and is unloaded from the cars by means of cranes carrying rectangular lifting magnets.

Fig. 1 is a view of the charging end of No. 1 Heating Furnace together with the Electric Overhead Travelling Crane serving it. The slabs are picked up by this Crane by means of a magnet and placed on the skids in front of the Massive Pushers. These machines are of unusually heavy design and are electrically controlled and operated. As hot slabs are drawn for rolling, cold ones are pushed into the furnace at the rear or charging end. Fig. 2 shows a partial end and side view of the No. 1 Heating Furnace with a portion of the Mill Approach Table, Roller Table and of the delivery end of the Slab Transfer in the foreground. Above the top of the furnace may be seen the pipes through which is conveyed the air and powdered coal, by means of which the furnace is heated.

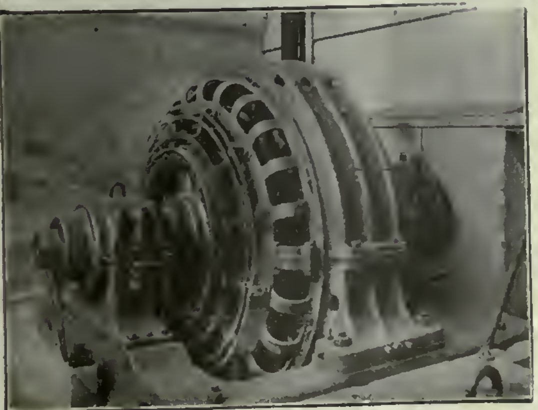

Fig. 3 is a view of the Westinghouse Reversing Mill Motor, which was designed and built especially for this installation. To one watching it in operation, it causes an almost uncanny feeling. Its silent and almost instant reversal from full speed in one direction to full speed in the opposite direction, giving no indication of the tremendous power being developed. This motor derives its power from a Motor Generator Set, which is shown in Fig. 4. To enable it to carry peak loads it is provided with a solid steel plate fly wheel. This form of construction is necessary in order to withstand the terrific stresses produced by reason of its high speed revolution—the rim of this fly wheel travelling more than four miles per minute.

Before any material is placed in stock or used, each piece is carefully inspected for seams, pipes, or any other defects which could be rolled into the steel by later manipulation and not detected until the material was in the customer's presses. The stockyard has a capacity of from fifteen

Fig. 5—This shows a view looking down through the mill from a point near the 24 in. Universal Mill Rollers Pulpit.

to twenty thousand tons of steel and adjoins the mill building.

Great care and attention were given to the design and detail for the furnaces to insure uniform heating. They are of the large continuous reheating type, using powdered coal as fuel. All parts and accessories were specially designed and constructed for this method of heating. Pushers, drawing machinery, door hoists, transfer tables and all equipment auxiliary to the furnaces are electrically operated. The steel is transferred to the roughing mill in a unique manner, and in such a way that practically all furnace scale is removed.

Roughing Mill

The roughing mill is a high-speed 24-inch two high universal mill and is driven by a Westinghouse reversing motor similar to those used in blooming mills but smaller and much faster. An idea of the extreme proportions of the mill will be conveyed by the statement that the housings weigh approximately 42 tons each, and that all other parts are correspondingly heavy. When it is borne in mind that this company produces large quantities of special alloy steels in the form of strips up to No. 00 gauge x 24 inches wide, the necessity for such heavy units will be appreciated. The extreme rigidity of the mill and foundations are also realized upon considering that when finishing 50 carbon steel less than one-thousandth of an inch (.001) is allowed for spring of the mill. The vertical rolls on this mill are designed and operated so that proper side work may be given the steel. This method of rolling also holds the width dimension to slight variation.

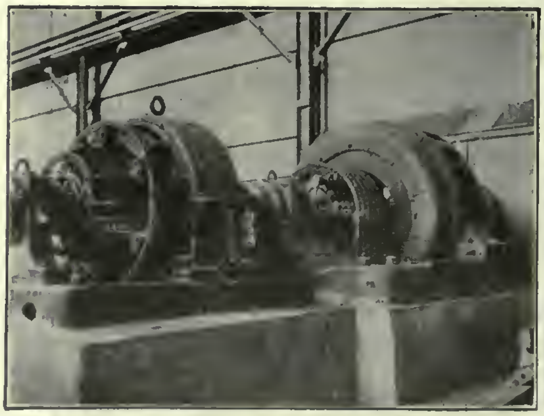
If the material is brought to gauge on the roughing mill, the strip is turned over after rolling in order to facilitate inspection and remove any slight remaining scale. It is then transferred to a leveller or straightener of extremely rugged construction. From this the product is delivered to the hot bed.

Finishing Light Material

When producing lighter material only the roughing operations are used on the roughing mill, as a train of finishing mills has been provided for the final passes. These mills are operated entirely by mechanical means—no manual labor being required. Driving power is furnished by a Westinghouse motor of the Kramer type, permitting a wide range of operating speeds with good electrical efficiencies.

From these mills the material is delivered to hot bed or coiler as may be required. On leaving the hot bed the strips are cut to length and piled by a mechanical piler, placed in stock if they are to be shipped as plain hot rolled material, or transferred to the finishing department if additional treatment is required.

In addition to the usual slitting, shearing, oiling and liming machinery, the finishing department has extensive facilities for heat treating and pickling. Each furnace has a charging capacity of approximately twenty-five tons and also the necessary mechanical means for reading and heat control, assuring uniform heat treatment. The furnace men can observe and control the furnace temperature at all times, but the recording instruments and the records are seen only by the department superintendent, who thus has a definite and accurate record of all conditions and every operation employed on past work. The pickling vats are of the plunger type in standard details, but of large size for pickling large pieces whether flat or coiled.



In Fig. 6 are shown the Transfer Tables serving the 16 in. Finishing Mill. The Westinghouse Motor used for driving this Mill is shown in Fig. 7. As in the case of the motors driving the Universal Mill this motor was also designed especially to meet the requirements of this particular installation.

The steam for heating pickle liquors and other miscellaneous heating processes is generated by a boiler placed over the annealing furnace flues.

Research Department

The research department continues further investigation through their physical and chemical testing laboratories. These laboratories provide to the inspection department all tests needed to insure thorough knowledge of materials produced, the extent of tests being dependent upon character, quality and ultimate use of material on order.

The plant has a number of unusual and interesting features.

(a) Electricity used for power throughout.

(b) Practical elimination of hard physical and hand labor which formerly has been the rule.

(c) Large clean, well lighted and well ventilated buildings.

(d) Extensive methods and extra care to eliminate scale.

(e) Unusual, heavy equipment to bring size variation to a minimum.

(f) Unusual rolling methods to produce steels and alloys in steel of superior quality and new characteristics.

Experiments, investigation and research as continued by this organization will doubtless develop further data and information to enable production of materials with other new qualities and characteristics, and thus the field for specialties manufactured from such source of supply will be extensively broadened and developed.

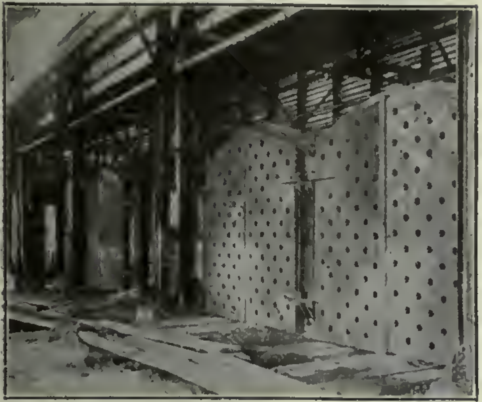
HOW WORKMEN TEST STEEL

The Steel Treating Research Society of Detroit have done good work in recent months in directing attention to the discussion of vital steel problems. At a recent meeting they were addressed by John F. Keller of Purdue University, Ind., who made some interesting statements regarding the methods by which workmen test various steels.

Some Common Methods

Among the various ways of judging the quality of steel, the most common are: trade or quality stencil marks, labels pasted on the bars, bars painted different colors, general shape of the material, appearance of surface, heft or weight, ring or tone of metal when dropped, feeling, intuition, smell, fracture test, fire and water test, service test, and spark test.

The first two are the most dependable methods, except that if the steel is kept in a damp place the labels will drop off in the course of time due to rust. The third method is dependable if a general scheme of colors is used for the different brands of steel and the system is intelligently applied. There is, however, in many factories extreme carelessness and indifference in the painting of valuable stock; in one factory seven grades of stetel were painted one color.



In Fig. 8 several of these furnaces are shown, while in Fig. 9 is shown a corner of the Pickling Department.

Shape

Many workmen select steel by its general shape; for instance, a hexagon section will represent screw stock and an octagon section will indicate cold chisel steel. But this method of selecting should not be tolerated, because steel can be manufactured into any form or shape desired, except stellite, which is cast into form. It may surprise some engineers to learn that many tool steels are selected by the appearance of the surface. If the bars are smooth and have sharp corners, it is evidence to the workmen of first-class steel. Without other evidence, expensive labor is put upon the tool and usually only when hardening is the mistake discovered. Smooth surfaces and sharp corners indicate work at low temperatures, while rough surfaces and round corners are caused by an iron ovide scale when the metal is laid down at high temperature; therefore, the appearance of the surface does not indicate the quality or composition of the metal.

Tone

Many workmen, not satisfied by the shape, appearance and weight, drop the metal on a hard floor or a heavy piece of iron; if the ring is a sharp tone, the metal is thought to be a good quality of steel. The finer the grain the more homogeneous the structure, and the harder the metal, the sharper is the tone. These qualities are developed by elements in the metal by working, and by heat-treating at a moderately low temperature. On the other hand, wrought iron will emit a dull tone owing to the presence of about 2 per cent. of slag and the usual methods of working such metal at a high temperature. This method is not reliable or dependable, because work and heat-treatment will affect the tones emitted when the material is struck or dropped.

It is surprising how many expert toolmen will select material by intuition; and because of their opinion they work the tool into shape regardless of any indication in its cutting properties that the metal may be undesirable. Their mistake is usually discovered when attempting to harden the metal or when putting it into service. It is said that in the southern part of the state a man nicks a bar of stock with a cold chisel, breaks it in two, and immediately smells the fracture, claiming that a good quality of steel smells like ammonia. There is no ammonia in steel. Many of the tests used by workmen are just as reliable.

Fracture

The fracture test does not represent the true quality of metal, but rather indicates the last heating operation to which the metal was subjected. A fracture that has a coarse granular appearance may not mean that the material is of inferior quality, but that it was laid down at high heat and the crystals retained the size corresponding to that heat. There are exceptions to this rule, however, for many of the elements in alloy stetels prevent or retard crystallization at high temperature. High-speed steel shows an unusually fine grain after being heated to 2,250° F.; on the other hand, carbon tool steel heated to its critical temperature and immediately quenched shows a fine silky structure, and it is doubtful if the average mechanic is able to distinguish these metals when they are placed together for comparison. If a small piece of carbon tool steel is heated to just above its critical temperature, about 1,450° F., known as a dark cherry red, and immediately quenched in water, it will be hard enough to resist a sharp file; and when fractured it should show a fine silky structure. If low or inferior grade of carbon steel is treated in this manner the surface may be hard enough to resist a file but the fracture will not show a fine structure.

Haphazard

Many workmen as well as the experimental engineer select available material at hand without any determination as to quality, and then put expensive labor upon the part or tool. When finished, it will be tried out in service, and if it fails, something else is tried. Such failures are usually found in the scrap heap. The service test, however, has its advantages if the engineer has a knowledge of the material so tested. This information is invaluable as it is the combination of successes and failures that gives the empirical knowledge that completes the perfect understanding of theory. A record of the life work of a piece of steel and accurate data are the most powerful tools that an engineer has. Therefore, the scrap heap of failures is the most instructive place about a plant.

The spark method is based on the action of the oxygen of the air on the combustible element present in iron and in many of the alloying elements contained in the different steels, which act explosively when heated to a temperature necessary for combustion. To produce bright sparks as the result of heating finely divided particles of metal, the heat must be intense enough to cause chemical combustion between the oxygen of the air and the particles of metal.

ENGINEERS WANT SPECIAL INSTRUCTION FOR WOMEN STUDENTS

At a recent joint session of the Detroit section of the American Society of Mechanical Engineers and the Detroit Engineering Society, the following motion was passed:

"WHEREAS the demands of the country for men and means to fight the war has resulted in a deficiency of skilled workers in the trades and professions; and

"WHEREAS the women of this country could with a short period of training fit themselves to fill these positions, as women have done in other countries at war; and

"WHEREAS among the things which women could do advantageously are, drafting and tracing, inspection and testing of materials, both physically and chemically; therefore

"RESOLVED that the universities, colleges and technical schools throughout the land be asked to consider the question of meeting this demand by providing special courses of instruction open to women students qualified to pursue such courses, and further

"RESOLVED that employers who could use such skilled help exert their influence with their universities, colleges and technical schools, and co-operate with them in developing and making available a great body of intelligent and adaptable women who are as eager and willing to serve their country as their brothers;

THEREBY bringing about not only increased effectiveness in fighting the war but also a greater mutual respect and saner relationship of our men and women."

Reconstruction Receives Organized Attention from the British Government

Eighty-seven Bodies in Fifteen Groups Cover the Field of Effort—Problems of the Future Are Being Foreseen When Possible and Every Preparation Made For Their Solution

THE manner in which the British nation has organized itself to meet each succeeding problem of the ar has been one of the most surprising atures of the times. The improbability at the world will be dominated by the ın has led to attention being given to timate conditions, and the question of w to prepare for them has resulted in eation in Britain of the Ministry of econstruction which has appointed rious commissions and committees to al with prospective problems.

The various matters dealt with cover ery phase of activity from trade de-elopment to the treatment of aliens—om coal and power to labor and em-oyment. The eighty-seven bodies are ranged in fifteen groups as follow, hile a summary of their constitution ıd scope is appended, the parentheses dicating the department which directs e particular committee.

I. Trade development, under which rouping are five committees dealing ith general aspects and nine dealing ith specific phases of the situation.

II. Finance, with two committees.

III. Raw materials, with six commit-ees.

IV. Coal and power, with two commit-ees and four sub-committees.

V. Intelligence, with two committees.

VI. Scientific and industrial research, ith two research boards, five standing ommittees, seven research committees, our inquiry committees, and three pro-isional organization committees.

VII. Demobilization and disposal of tores, with eight committees.

VIII. Labor and employment, with two ommittees.

IX. Agriculture and Forestry, with our committees.

X. Public Administration, with six ommittees.

XI. Housing, with four committees.

XII. Education, with eight commit-ees and commissions.

XIII. Aliens, with two committees.

XIV. Legal, with three committees.

XV. Miscellaneous, with three commit-ees.

An idea of the many matters which it s believed will require careful consider-ition upon the cessation of hostilities nay be gained from a summary of these commissions and committees; directed in each case by the department indicated in parentheses after the name of the com-mittee.

The Development of Trade

Commercial and Industrial Policy Committee (the Prime Minister).—To consider the commercial and industrial policy to be adopted after the war, with special reference to the conclusions reached at the economic conference of the Allies and to the following questions: (a) What industries are essential to the future safety of the nation, and what steps should be taken to maintain or establish them? (b) What steps should be taken to recover home and foreign trade lost during the war and to secure new markets? (c) To what extent and by what means the resources of the em-pire should and can be developed? (d) To what extent and by what means the sources of supply within the empire can be prevented from falling under foreign control?

Dominions Royal Commission.—To in-quire and report upon (a) the natural resources of the five self-governing do-minions and the best means of develop-ing these resources; (b) the trade of these parts of the empire with the United Kingdom, each other and the rest of the world; (c) their requirements and those of the United Kingdom in the mat-ter of food and raw materials, together with the available sources of supply; (d) to make recommendations and sug-gest methods consistent with existing fiscal policy by which the trade of each of the self-governing dominions with the others and with the United Kingdom could be improved and extended.

The Development of Industries

Industrial Development Commission (Government of India).—To examine and report upon the possibilities of further industrial development in India and to submit its recommendations with special reference to the following questions: (a) Whether new openings for the pro-fitable employment of Indian capital in commerce and industry can be indicated; (b) whether, and if so, in what manner, the government can usefully give direct encouragement to industrial development (1) by rendering technical advice more freely available, (2) by the demonstra-tion of the practical possibility on a commercial scale of particular industries, (3) by affording, directly or indirectly, financial assistance to industrial enter-prises, or (4) by any other means which are not incompatible with the existing fiscal policy of the government of India.

Belgian Trade Committee (Foreign Office and Board of Trade).—(1) To in-quire into all matters relative to trade between the British Empire and Belgium with a view to increasing and developing that trade by every desirable means; (2) to investigate as far as possible all means to be adopted in order to attain the object set out in par. 1. The com-mittee will examine into the supplies and requirements of the respective countries (in so far as they have relation to its scope) and give advice as to how trade between them can be best established, developed and increased. It will obtain information and evidence from all avail-able sources and endeavor to render all possible assistance in regard to shipping, manufactures, imports and exports, and trade generally between the empire and kingdom; (3) the committee will consist of three representatives appointed by the Foreign Office and three representa-tives appointed by the Board of Trade. A chairman and secretary will be chosen from their number. The committee shall have power to add to its numbers by the appointment of such persons of ex-perience in the matters with which it has to deal as it may think expedient, and it will also consult from time to time other representatives of commerce hav-ing special knowledge of Belgian trade, shipping and finance; (4) it is particu-larly laid down that the purpose of this committee shall be a general one and that it shall not be part of its duties to foster the advancememnt of the trade of any particular individual or firm nor to devote its assistance to any special branch of trade or industry except in re-lation to the general principles for which it is established.

Trade Relations After the War Com-mittee (Board of Trade).—To investi-gate the general questions of trade re-lations after the war with a view to the successful promotion of British trade, and also with the object of devising measures for the prevention of the ef-fective resumption of Germany's policy of peaceful penetration.

Committee on the Chemical Trades (Ministry of Reconstruction).—To advise as to the procedure which should be adopted for dealing with the position of th chemical trade after the war, with a view to the creation of some organiza-tion which should be adequately repre-sentative of the trade as a whole and by means of which the trade may be enabled hereafter to continue to develop its own resources and to enlist the closest co-operation of all those engaged in the chemical industry.

The Engineering Trades

Engineering Trades (New Industries) Committee (Ministry of Reconstruction). —To compile a list of the articles suit-able for manufacture by those with engineering-trade experience or plant, which were either not made in the United Kingdom before the war, but were im-ported, or were made in the United Kingdom in small or insufficient quantities, and for which there is likely to be a considerable demand after the war, classified as to whether they are capable of being made by (1) women, (2) men and women, or (3) skilled men; and setting out the industries to which such new manufactures would most suitably be attached; and to make recommendations (a) on the establishment and development of such industries by the transfer of labor, machines, and otherwise; (b) as to how such a transfer could be made, and what organization would be requisite for the purpose, with due regard to securing the co-operation of labor.

Board of Trade Committees on the Coal, Electrical, Engineering, Iron and Steel, Nonferrous-Metal and Textile Trades, and on the Shipping and Shipbuilding Industries.—To consider the position of these trades and industries after the war, with special reference to international competition, and to report what measures, if any, are necessary or desirable to safeguard that position.

Financial Facilities Board

Financial Facilities Committee (Treasury and Ministry of Reconstruction).—To consider and report whether the normal arrangements for the provision of financial facilities for trade by means of existing banking and other financial institutions will be adequate to meet the needs of British industry during the period immediately following the termination of the war, and, if not, by what emergency arrangements they should be supplemented, regard being had in particular to the special assistance which may be necessary (a) to facilitate the conversion of works and factories now engaged upon war work to normal production; (b) to meet the exceptional demands for raw materials arising from the depletion of stocks.

Enemy Debts Committee (Foreign Office).—To report on the arrangements to be adopted for the liquidation of the commercial, banking and other financial transactions between British and enemy persons, the completion of which was prevented by the outbreak of war, and for this purpose to consider the returns made to the custodians of enemy property, and to the public trustee and the foreign claims office, and any information on matters relating thereto.

Committees on Raw Materials

Central Committee on Materials Supply (Ministry of Reconstruction).—To consider and report upon (1) the nature and amount of the supplies of materials and foodstuffs which in the committee's opinion will be required by the United Kingdom during the period which will elapse between the termination of the war and the restoration of a normal condition of trade; (2) the probalbe requirements of India, the dominions and crown colonies for such supplies at the close of hostilities; (3) the probable requirements of belligerents and neutrals for such supplies at the close of hostilities; (4) the sources from which and the conditions under which such supplies can be obtained and transported and in particular the extent to which they might be obtained from the United Kingdom or within the empire or from allied or neutral countries; (5) the question whether any measure of control will require to be exercised in regard to the nature and extent of any such control.

Building Materials Supply

Committee on the Supply of Building Materials (Ministry of Reconstruction). —(1) To inquire into the extent of the probable demand for building material for all purposes which will arise in the country during the transition period and the extent of the available supply and form of such material; (2) to inquire how far the quantities of material now available are capable of increase, what are the difficulties in increasing them, and how these difficulties can be removed, and to report to what extent an increase in production will affect the price of the materials; (3) in the event of the supply of material or labor being insufficient to fulfill the total building demand, to consider the principles and method by which the priority of various claims should be settled, and to report what steps are necessary to insure that the manufacture of the materials, so far as they are at present inadequate, shall be extended in time to secure sufficient quantities for use when required on the cessation of hostilities and to recommend what steps should be taken during the war to facilitate a prompt commencement of building work at that time; (4) generally to consider and report upon any conditions affecting the building trades which tend to cause unduly high prices and to make recommendations in regard to any measure of control which it may be desirable to exercise over the purchase, production, transport or distribution of materials.

Cotton at Home and Abroad

Committee on Cotton Growing Within the Empire (Board of Trade).—To investigate the best means of developing the growing of cotton within the empire and to advise the government as to the necessary measures to be taken for this purpose.

Coal Conservation Committee (Ministry of Reconstruction).—To consider and advise (1) what improvements can be effected in the present methods of mining coal with a view to prevent loss of coal in working and to minimize cost of production; (2) what improvements can be effected in the present methods of using coal for production of power, light and heat, and of recovering by-products with the view to insure the greatest possible economy in production and the most advantageous use of the coal substance; (3) whether, with a view to maintaining industrial and commercial position, it is desirable that any steps should be taken in the near future, and if so, what steps to secure the development of new coal fields or extensions of coal fileds already being worked.

Mining, Power Generation and Transmission, Carbonization and Geological Subcommittees.—The question of the application of carbonization to the preparation of fuel for industrial and commercial purposes.

Committee on Supply of Electricity (Board of Trade).—To consider and report what steps should be taken whether by legislation or otherwise, to insure that there be an adequate and economical supply of electric power for all classes of consumers in the United Kingdom, particularly industries which depend upon a cheap supply of power for their development.

Scientific and Industrial Research

The following 21 committees have been established by the department of scientific and industrial research:

Fuel Research Board.—To investigate the nature, preparation and utilization of fuel of all kinds, both in the laboratory and, where necessary, on an industrial scale.

Cold Storage Research Board.—Appointed to organize and control research into problems of the preservation of food products by cold storage and otherwise.

Standing Committees on Engineering, Metallurgy, Mining and Glass and Optical Instruments.—To advise the council on researches relating to the lines of activity named and on such matters as may be referred to the committee by the advisory council.

Joint Standing Committee on Illunminating Engineering.—To survey the field for research on illumination and illuminating engineering, and to advise as to the drections in which research can be undertaken with advantage.

Mine Rescue Apparatus Research Committee.—To inquire into the types of breathing apparatus used in coal mines, and by experiment to determine the advantages, limitations and defects of the several types of apparatus, what improvements in them are possible and whether it is advisable that the types used in mines should be standardized, and to collect evidence bearing on these points.

Abrasives and Polishing Powders Research Committee.—(1) To conduct investigations on abrasives and polishing powders with a view to their preparation and use as one factor in accelerating the output of lenses and prisms for optical instruments not only for peace requirements but in connection with the war; (2) to investigate the preparation and properties of abrasives and polishing powders.

Food Research Committee.—To direct research on problems in the cooking of vegetables and meat, and in bread making, to be undertaken by two scholars of the committee of council.

Building Material Research Committee. —To make arrangements for carrying out researches on building construction instituted by the department at the instance of the Local Government Board Committee or otherwise, to be responsible under the council for the direction of such researches, and to deal with such other matters as may be referred to the committee from time to time by the council.

Electrical Research Committee.—A committee of direction appointed in connection with certain researches affecting the electrical industry.

Committee for Research on Vitreous Compounds and Cements for Lenses and Prisms.—To conduct researches into the preparation, properties and mode of employment of cements for lenses and prisms; to prepare a reference list of vitreous compounds, their composition, densities, refractive indices and dispersive powers.

Tin and Tungsten Research Board. — The Cornish Chamber of Mines has been invited to nominate a representative of the landlords and a representative of the mine owners to serve on the board. A committee of control appointed in connection with certain researches into tin and tungsten.

Lubricants and Lubrication

Lubricants and Lubrication Inquiry Committee.—To prepare a memorandum on the field for research on lubricants and lubrication, which will contain an analysis of the problems involved, together with a suggested scheme of research, which would be most likely to lead to valuable results.

Chemistry of Lubricants Subcommittee. —To collect and review the existing information relating to the chemistry of lubricants and lubricating oils.

Zinc and Copper Research and Inquiry Committee.—To collect and review the existing information as to the copper and zinc industries upon which future research must be based, to formulate proposals for carrying out research suggested by the Brass and Copper Tube Association of Great Britain into the best methods of making sound castings of copper and brass for tube making and to prepare an estimate of their cost, and to report to the advisory council.

Irish Peat Inquiry Committee.—To inquire into and consider the experience already gained in Ireland in respect of the winning, preparation and use of peat for fuel and for other purposes, and to suggest what means shall be taken to ascertain the conditions under which in the most favorably situated localities it can be profitably won, prepared and used, having regard to the economic conditions of Ireland; and to report to the Fuel Research Board.

Demobilization and Disposal of Stores

Demobilization of the Army Committee.—To consider and report upon the arrangements for the return to civil employment of officers and men serving in the land forces of the crown at the end of the war.

Officers' Resettlement Subcommittee.— To consider and report what arrangements require to be and can be made on demobilization for resettlement of officers in civil life, and also of men belonging to classes to which in the main officers belong.

Disabled Officers' Employment Committee (India and Colonial Offices).—To assist disabled or invalided officers who may be desirous of obtaining employment in India, Burma, the Eastern colonies and Malay States.

War Office Demobilization Committee. —To consider questions requiring settlement in connection with the demobilization of the army in so far as they fall within the province of the war department; to act as a link with the committee of the Ministry of Reconstruction, and to prepare a draft scheme of demobilization.

Demobilization Coordination Committee (Admiralty, War Office and Ministry of Labor).—(1) To consider how far the proposed special arrangements to demobilize immediately peace is declared men specially required in connection with the work of demobilization can or should be extended to other men belonging to the public services or to similar "pivotal" men in industry; (2) to coordinate the working of the demobilization scheme of the war department with the resettlement scheme of the ministry of labor; (3) to settle, during demobilization, instructions with regard to priority which may appear to be rendered necessary on public grounds or by the sort of employment in the different industries.

Civil War Workers

Civil War Workers' Committee (Ministry of Reconstruction).—To consider and report upon the arrangements which should be made for the demobilization of workers engaged during the war in national factories, controlled establishments and other plants engaged in the production of munitions of war and on government contracts or in plants where substitute labor has been employed for the duration of the war.

Horse Demobilization Committee (War Office).—To frame proposals for the demobilization of horses and mules in relation to the general scheme of demobilization.

Disposal of War Stores Advisory Board (Ministry of Reconstruction).—To expedite the preparation of any necessary inventories of property and goods of all descriptions held by government departments, and to consider and advise upon the disposal or alternative form of use of any property or goods which have or may become during or on the termination of the war surplus to the requirements of any department for the purposes of that department.

Labor and Employment

Committee on Relations Between Employers and Employed (Ministry of Reconstruction)—(1) To make and consider suggestions for securing a permanent improvement in the relations between employers and workmen; (2) to recommend means for securing that industrial conditions affecting the relations between employers and workmen shall be systematically reveiewed by those concerned with a view to improving conditions in the future.

Women's nployment Committee (Ministry of Reconstruction)—To consider and advise in the light of experience gained during the war upon the opportunities for the employment of women, and the conditions of such employment in clerical, commercial, agricultural and industrial occupations af ter the war.

Aliens Committee (Ministry of Reconstruction).—To consider (a) the questions which will arise at the end of the war in connection with the presence in this country of persons of an enemy nationality and whether the repatriation of such is desirable, and if so, in what cases; (b) what restrictions, if any, should be imposed after the war on admission of aliens to this country and their residence here; (c) whether any changes in the law or practice of nationalization have been shown by the experience of the war to be required in the public interest.

Interdependent Conference on Missions in India.—To consider the conditions on which aliens should after the war be allowed to conduct missionary or educational work in India.

Civil Aerial Transport Committee (Air Ministry).—To consider and report to the air board with regard to (1) the steps which should be taken with a view to the development and regulation after the war of aviation for civil and commercial purposes from a domestic and imperial and an international standpoint; (2) the extent to which it will be possible to utilize for this purpose the trained personnel and the aircraft which the conclusion of peace may leave surplus to the requirements of the naval and military air services of the United Kingdom and overseas dominions.

SEVERE COLD working of a metal is apt to produce the form of decay known as seasoning cracking. Hard drawn brass rods and tubes occasionally crack, both in use and in storage, when transferred to a warmer climate or exposed to slight corrosion. This decay is due to the existence of severe internal stresses in the metal caused by the unqual deformation of the inner and outer layers. The cracks are commonly transverse. While seasoning cracking is generally hastened by exposure to temperatures above normal, heating sometimes prevents this form of decay. Seasoning cracking may also be caused by ammonia or other agents; when the chemical agent acts rapidly the cracking may occur with almost explosive violence. Very hard drawn rods of brass or bronze will sometimes fly to pieces when attacked with a solution of a mercury salt or of ferric chloride.

A SUITABLE varnish for rust prevention can be manufactured from the following recipe:—Resin six parts, sandarac nine parts, gumlac three parts, turpentine six parts, and rectified alcohol nine parts. The resin, sandarac and gumlac should be mixed together in a pounded condition and then carefully heated until melted. When they are well melted, the turpentine should be added very gradually, stirring all the while. The mixture should then be digested until dissolution takes place. Then add rectified alcohol up to the amount stated above. It should afterwards be filtered through fine cloth or thick filter paper and preserved in well-stoppered bottles so that no evaporation can take place.

HANDLING MATERIAL FOR ASSEMBLIES

By D. O. Barrett

IN any establishment involving the assembling of finished stock the basis of all recorded observations is, of course, the bill of material listing the various parts to be used, together with sizes of same, kind of material, and any other pertinent information. These bills are made out for all the smaller units of the machine which may be assembled and carried in stock as such. The general bill will then cover the entire machine, this comprising the various assemblies together with the other items necessary.

A sample bill of material is shown for a piston assembly for an oil engine, the rod and rings being fitted and the whole carried as a unit entering into the final assembly of the engine. It is not the purpose here to enter into any lengthy discussion of stockroom practice but merely to show a couple of methods which have been used to cover the transfer of stock to the assembly floor and give a complete record of same, enabling an accurate cost to be obtained of the finished machine.

The long card shown was used in the assembling of farm tractors. When the order came to the shop to assemble a certain number of machines the cost clerk made out one of these cards for each tractor in the lot, this bearing the serial number as well as designating the type and any specials to be carried. This card constituted the order on which the assembly foreman built the machine. When ready to start work, the bottom stub of the card was removed and turned into the stockroom which then supplied all the material called for on the bill specified. The stockkeeper then returned this stub to the cost clerk, who checked out of "finished stock" and charged to "work in process," the complete bill of material. The card was perforated between the various stubs so that these could be easily removed. A rubber stamp was used in filling in the card with tractor number, size, etc. This tag was tied to the tractor in a conspicuous place so that it could be inspected at any time during its progress. When completely erected the inspector removed the corresponding stub and sent in with his O.K., the tractor then going to the test shop, and as each operation was completed the corresponding stub was sent in to the cost clerk so that the man in charge of production could tell at a glance where any certain tractor was located and whether production was being kept up to the predetermined schedule. No requisitions were required to secure any material as the proper stub served this purpose while all reference to the amount of material necessary was made to the original bill of material as specified by number on the stub. This method worked very satisfactorily as it enabled a careful check at all times on machines going through the shop.

In the building of large oil engines the conditions were somewhat different from those encountered in the manufacture of tractors. Where the latter could be put through in large lots it was often necessary for the assembler to work on several of these larger engines before one would be entirely finished. It was quite a job for the stockkeeper to record all the various material as called for as it was obviously impossible to deliver the amount for a complete engine at one time. Mistakes were constantly occurring in trying to charge off the various items from the stock cards which, in this case, were kept in the stock room. To obviate this trouble a combined bill and checking list was printed, one of these being made out for each engine at the time the assembly order was given. Of course the most of the information at the top of the sheet could not be entered until the engine was shipped.

Several sheets were required for a complete engine and these were bound together, being practically a repetition of the general bill of material though it did not replace this and was intended to be used for all the various sizes of the same type. As the material was called for and issued a small rubber stamp was used

BILL OF MATERIAL USED IN TRACTOR WORK.

to record the date in the proper column. As much information as possible concerning the engine was put on the sheet so as to form a complete and permanent record which might be used later for reference should any repairs be ordered. In engines of this size it is impossible to discard pieces which may not come exactly to specified sizes and another piece may be especially made to fit them. Naturally, if some record is not made of this, trouble will occur later should a duplicate of one of these pieces be ordered. When the engine was completely assembled the material was all charged off the stock cards. No material other than called for on the regular bill of material was given out and, should any be needed, it was necessary for the assembler to secure a requisition from the foreman and the material was then entered on one of the blank lines.

When the sheets were sent to the office the prices were filled in from the cost cards and the value of the completed engine as shipped, obtained. For the class of work for which it was used this method gave results which were accurate and with a minimum of labor.

BABBITTING BEARINGS

By D. A. Hampson.

"M. H. P.'s" article on babbitting in the May 16th issue is so complete and so clear that one hesitates to add anything to it. However, a few supplementary thoughts may not be out of place entirely.

When babbitt is heated in a pot and poured from ladles dipped in the pot chilling is bound to occur. If cold ladles are dipped in the molten babbitt the temperature of the babbitt in both the ladles and the pot is considerably lowered—often so much that by the time the second ladleful reaches the bearing it is entirely too cool to attempt to pour. A remedy for this trouble is to heat the ladle or ladles with the babbitt as soon as it softens up; with this method the ladle is of the same temperature as the babbitt when pouring begins and the first and subsequent dippings do not start wrong by cooling the metal far below pouring temperature.

The writer has poured plenty of bearings with paper wrapped around the shaft, but must confess that in the hands of the average workman, who only runs a bearing once in a while, the method can not be called a success. On a rough job, where the object is simply to fill a hole or where the bearing is to be bored, the paper may do, though it is fussy at best, and he who doesn't get the babbitt inside the paper at times is lucky indeed. If a lubricant is desired to get the mandrel out easily or as a protection for the shaft, a coating of red or black lead is about the best thing going. Red lead is obtainable at the most distant jobs; if rubbed on the mandrel evenly and heavy enough so the latter shows its own color just faintly, the bearing when poured will be a running fit and needs but a touch with a scraper. In manufacturing a line of machines which required a good many square threaded babbitted nuts one of the slowest jobs was to get the screws out of the nuts and to scrape and tap the nuts to a decent working fit. The writer

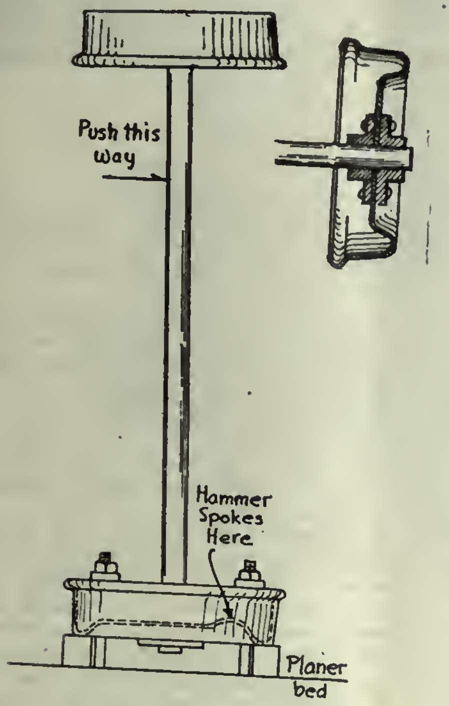
tried the red lead scheme on the nuts and did away with all those slow processes at one stroke. The lead (powder) is mixed to the consistency of paint and applied to the screws with a brush; this gets it on the sides of the screw as well as top and bottom. The screws, after pouring, are turned out of the nut with a ¾-in. lathe dog, though the dog is needed only for a starter, for as soon as



METHOD OF STRAIGHTENING WHEELS.

started the screws can be turned by hand and are found to be a first-class running fit without shake.

A mistake made by too many is in not providing means for the air to escape. It is not uncommon to see babbitt blown fifteen feet in the air by failing to provide an escape for the air which was trapped and compressed. If an unusually large pouring hole is provided the stream of babbitt being poured does not shut it entirely, and an outlet is thus provided. But in most small work we see one or two ¼-in. holes, one or both of which are used for pouring holes. If only one hole is used for pouring, the air can escape from the other very nicely, but if there is only one hole (and that of such small size) that rarely is sufficient, and we have a demonstration of that old principle of physics that "two bodies cannot occupy the same space at the same time."

Too small a pouring is bad practice in any case where a larger one can be put in. A ½-in. hole is as small as should be used; it gives the workman a chance to "hit the hole" with the babbitt and also to let out a little air. But with the large hole, one or more small ones for the air to get out are advisable; if the casting is intricate, they help greatly in filling up all over. And once the pouring has been started, it should be kept up just as fast as the metal will run through the hole—better faster than slower.

STRAIGHTENING A CAR WHEEL

By M. I. D.

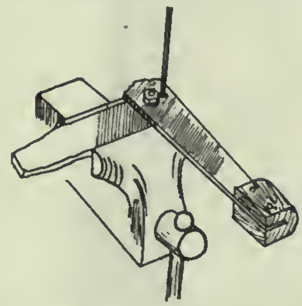
Pressed steel wheels are fast replacing cast iron ones for service on hand and gasoline propelled rolling stock used by inspection, electrical, and track gangs on our modern railroads. A section through a typical wheel is shown in Fig. 2. The steel is ¼-inch thick, it is centred in a cast hub, and driven through a 1½-inch axle. Every once in a while one of these axles would get bent and would be brought in for us to straighten. At least, the men said the axles were bent—we invariably found the fault to be in the wheel.

Our way of straightening the wheel is shown in the accompanying sketch. The wheel was first tested to locate the high side, in the lathe if the bend was small and by eye if it was very noticeable, and then the assembly was clamped on the bed of a heavy planer with the bad wheel down. This wheel was clamped so the bend was in the direction of the length of the bed. Two men stood on the planer and, using the axle as a bar, pushed and pulled in the right direction while a third hammered on the kink in the "spoke." By bending and trying, the wheel would be straightened in short order, often a badly bent one being fixed in a half hour's time. The axles were invariably of a size to resist any deformation during the work.

A MILLION PIECES OF HARD WIRE —HOW THEY WERE CUT OFF

By D. A. Hampson.

One of the operations in a munition job that the shop had taken "on contract" was to cut up a million pieces of ⅛-inch spring wire in various lengths from 1 inch to 30 inches. Now the shop had handled quite a little wire work in times past and had cutters for various sizes of a type shown in Fig. 1. Two worn-out files would be softened, teeth ground off one side of each and tangs cut off, and a pivot bolt put through one end. Then a hole to suit the size of wire to be cut would be drilled quite close to

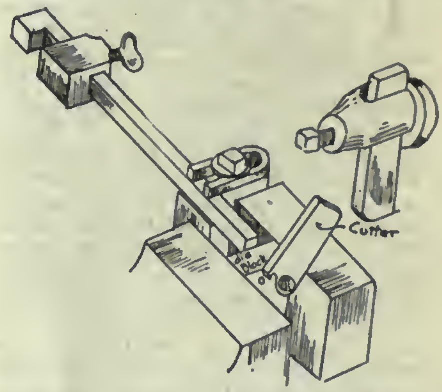


HAND SHEAR FOR CUTTING WIRE

the pivot and the ex-files hardened again. In use one of the blades would be held in a vise and the other, drilled to stand at right angles, would be pulled by hand to cut the wire. This made cheap, durable, and always obtainable cutters but not applicable to so many pieces at a time or such hard wire—besides being too slow, it would develop a sore hand squad of too large proportions.

Fig. 2 shows the wire cutter as made up and operated in a not-much-used shaper. A tool steel block with a hole for the wire to slide through is held in the shaper vise. The block carries a cutter kept up close by a shoulder screw and returned by a coil spring. A piece in the tool post strikes the cutter at each forward stroke and shears off the wire. The hole in the block is tapered up to within ¼ inch of the cutting edge running back to ⅝-inch at the rear and making it easy for the workman to find the hole with the wire. Straightened spring wire in standard three-foot lengths was purchased. In cutting up, the longest lengths were cut first, followed by shorter ones down to the smallest and reducing the waste to almost nothing.

There were in use in the shop gauges of the sliding jaw type with bars of

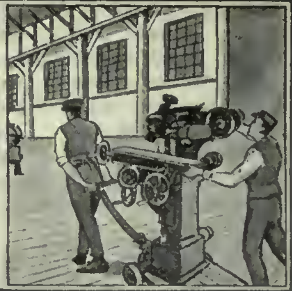


CUTTING A MILLION PIECES OF WIRE IN A SHAPER.

about 1 inch square section. One of these was requisitioned as a stop for length and clamped so the adjustable jaw was in line with the cutting hole in the block. This formed a most convenient arrangement and like the rest of the outfit tied up very little money in special tools to be discarded when the job was over. With the shaper running at forty strokes a minute, the operator was able to cut a wire every other stroke. But four sharpenings were necessary on the entire job, less would have done but for the fact that a very square end and a round wire right up to the end were required.

IN SOME hydraulic power stations there is, at certain seasons of the year, a surplus of energy available, which is commonly unavoidably run to waste. This has been the case (says Engineering) at the Leten power-station of the Zurich Electrical Power Company. At the same time it has been necessary to maintain for certain purposes a small steam plant. The company accordingly decided to utilize the surplus of power available for maintaining steam in a boiler for this plant. The boiler fitted has 1,800 sq. ft. of heating surface, and, with a maximum consumption of 84 to 86 kw., is able to supply 3,800 lb. of steam per twenty-four hours, which suffices to run the feed-pumps and to keep hot the machines and the piping.

DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

IMPROVED FLOOR TYPE BORING, MILLING AND DRILLING MACHINE

THIS machine is driven from a motor mounted on top of the column. The drive is direct connected to main drive shaft, there being no belting whatever involved in this design. The spindle drive is controlled by a pair of friction cone clutches, located at back of saddle, and accessible for adjustment. This arrangement provides a reversal of spindle for back facing and tapping. The driving pinion for the spindle meshes with a large diameter gear face cut directly on the face plate. This location of spindle drive prevents spindle torsion, and as a result eliminates one of the most frequent causes of chatter when milling. The front end of spindle slides through an adjustable bearing carried in the spindle sleeve, but the spindle does not rotate in this bearing. The rotating motion is taken in another adjustable bearing, and on the external diameter of the spindle sleeve. The advantage of this design is a provision of take-up for wear on the sliding spindle bearing.

A very prominent feature of this tool, and one which is exclusive in this design, is the sensitive and powerful concentric screw feed of spindle, accomplished by means of a differential train of gears. The only thing that limits the length of spindle feed when it is traversed by this method is the factor of practicability, as there is no mechanical limit of feed, such as is encountered with a rack and pinion or an auxiliary screw feed. This method of feeding permits continuous traverse of spindle without resetting. The feed is applied between main bearings, requiring no overhanging support at end of saddle.

The spindle is traversed by a long bronze nut which engages square thread on the spindle, and which has a bearing only on the sides of the spindle thread. It will be seen that this arrangement provides a very long bearing, and as the two rotate together at the same rate of speed, except when feed is engaged, the possibility of wear is very remote. However, in case of wear, there is an adjustment to take it up. The end thrust in either direction is taken on ball bearings

The thrust of spindle when milling is taken in a most rigid manner, directly on the main saddle casting, and is entirely independent of the end thrust of spindle for boring. The principle of carrying feed and speed gear trains in the saddle as one unit lends to the machine a facility for operation not readily surpassed.

There are twelve changes of speed, and twelve changes of feed embodied in this design. All feeds are at the same rate per revolution of spindle, whether applied to spindle, saddle or column traverse, and no two of them can be engaged at the same time. It is notable in connection with this speed and feed arrangement that any one of the twelve feeds can be applied to any one of the twelve spindle speeds, making in reality one hundred and forty-four actual rates of feed. Power rapid traverse, independent of the regular feeds, is provided for spindle, saddle and column in every direction. With one lever, machine can be instantly started and stopped, or reversed, independent of main drive or motor.

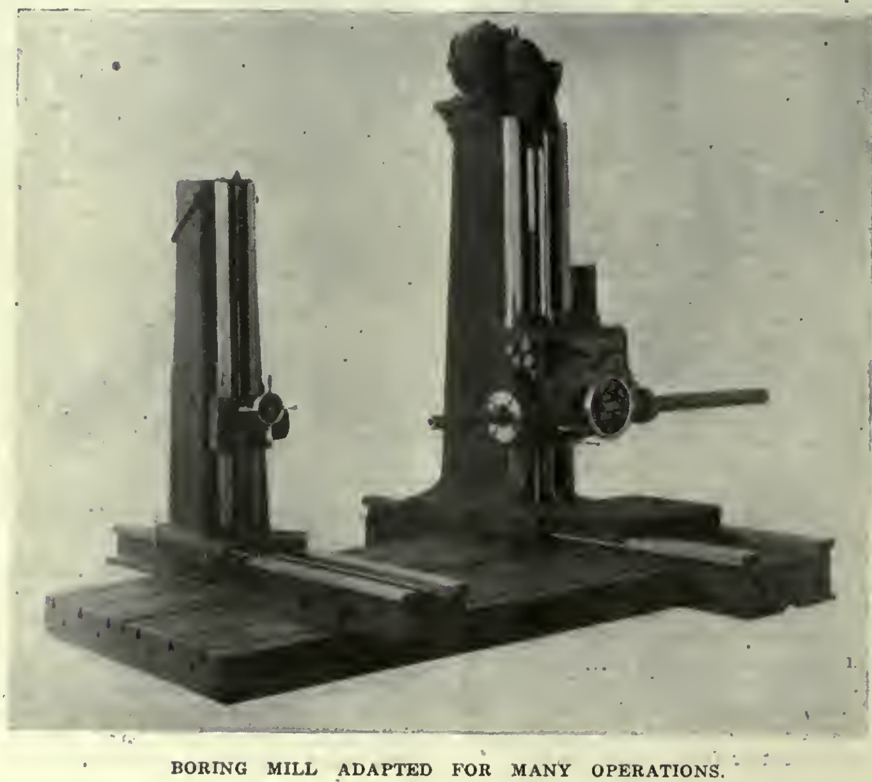
The gear shifts are all of the sliding transmission type, and are tightly and neatly enclosed, a feature that adds not only to the life and appearance of the machine, but also provides that safety for the operator so essential to State law requirements and rapid production of work.

All traversing gears are located consistent with the most approved methed of design, that is, between the ways, and close to the guiding side.

The gears and shafts are made of chrome nickel steel, specially heat treated. The spindle is made of high carbon hammered crucible steel and accurately ground to secure correct alignment.

The oiling of the saddle parts is accomplished by the syphon system, which insures a continuous supply of clean oil to the bearings. The counterweight for the saddle operates inside the column, out of the way of the operator, thus assuring safety in accordance with State laws.

When this machine is correctly aligned in position with the rigid outer support column, and the wide, unyielding floor plate, it possesses to a remarkable degree those features which make it an indispensable tool in factories and shipyards handling a variety of massive



BORING MILL ADAPTED FOR MANY OPERATIONS.

castings which must be machined accurately and quickly.

After several years of experience, designing and experimenting in a very practical way, the manufacturers of this machine are thoroughly convinced of its high efficiency under severe service. One of its greatest advantages is its universal range of adaptability. It may be used to bore, mill, drill, tap, spline, and for oil grooving or rotary planing at one setting. When swivel table is used, the different sides of work may be finished without resetting. The design of this machine is such that its actual manipulation requires a relatively low proportion of the operator's time, creating a wider opportunity, and a greater incentive, for him to increase production.

GEAR BOX WITH COVER REMOVED SHOWING MECHANISM.

This machine, of improved design, is built by the Landis Tool Company, of Waynesboro, Pa. It has been designed especially to meet the requirements in a general way, of shipyards, navy yards, turbine works, etc., and will handle a wide range of heavy machine work. Briefly it combines the necessary durability and simplicity of operation to insure accuracy and quantity of all work usually machined on floor type boring machines.

JULY MEETING OF ONTARIO SECTION OF A. S. M. E.

A well attended meeting of The American Society of Mechanical Engineers, Ontario Section, and the Toronto Branch of the Engineering Institute of Canada was held in the lecture room of the Engineers' Club on Wednesday evening, July 3. Two subjects were presented.

The first was a very interesting paper by Mr. Edward Maybee on "Patents of Invention." This covered particularly the part of the patent field of interest to engineers and a number of points which are generally not well understood were explained in a very clear and interesting way by Mr. Maybee.

The second subject was an address by Mr. Holmes of the Invalided Soldiers' Commission on "The Training of Disabled Soldiers in the Industries." The training of returned soldiers falls into three classes—that of the hospitals, then in the re-education schools and lastly in the shops of the industries themselves. With this last department Mr. Holmes dealt and explained the organization and methods of handling the work. It is with this industrial phase of the training that the engineers and employers should be closest in touch. It is here that they can help most.

Mr. Holmes explained how the preliminary survey is made of each plant before men are placed there and that a careful supervision is kept over the men and their work by the Government Commission during the period of their instruction. The men receive pay from the Government and instruction from the firm. Over 90 per cent. of the men so placed have made good and are now earning or making good progress towards earning a comfortable income.

The principal point brought out was that the returned men should not be dumped upon the industrial field and left to shift for themselves but their cases must be studied individually and the men allotted to positions suiting not only the man's natural capacity but also the nature of his wounds or physical deficiency.

PERMANENT EXHIBITION OF MACHINERY IN NEW YORK CITY

A permanent display and salesroom for machinery and mechanical appliances is being planned in New York City, to be operated by what is known as the Merchants and Manufacturers' Exchange of New York, the display and salesroom being located in the Grand Central Palace, Lexington Ave. and 46th St. The machinery exhibition will occupy an entire floor of the building, having an area of 50,000 square feet of floor space. For the convenience of the buyer, a general information bureau and reading room will also be maintained where important trade and technical journals and catalogues will be kept on file. All communications should be addressed to the Machinery Sales Department, Grand Central Palace, New York City.

KAING GRASS grows in great profusion in all parts of Burma, frequently reaching a height of 10 ft. As a paper-making material it may be classed with esparto grass, and is much cheaper, though the quality of the pulp is not quite so good as that obtained with esparto.

COAL AND COLD

ADVICES from all coal producing centres in Canada and the United States reveal a similarity of opinion regarding the coal situation which demands all the attention and action which it is possible to give.

Some time ago it was stated that no coal would go to Montreal from Nova Scotia this summer for the simple reason there are no ships available. While there may be some small amount taken up by rail, the great bulk of the fuel supply must be water-borne during the shipping season.

It is now stated that the Nova Scotia coal output continues to decrease. Commenting on this the Sydney correspondent of CANADIAN MACHINERY writes:

> "For the first six months of 1918 the production has fallen off from the record of the first six months of 1917 by about 330,000 tons, and it is only too probable that by the end of the year the total outputs will be less than those of 1917 by about 330,000 tons, and it is only too probable that by the end of the year the total outputs will be less than those of 1917 by almost half a million tons. At the same time it is hoped the rate of decline in the last half of 1918 will not be so rapid as it was during the last six months. That is the best that can be hoped for."

The problem of coal production is not the least of the problems that face the Allied leaders, and if the coal production declines to a point where it restricts the output of munitions and the transport of troops the gravity of the situation will appear in its true light. According to our authority quoted above things are approaching such a point that if activities vital to the success of the war are touched the private consumer will have to freeze, if need be, because the needs of the army and navy come before the requirements of people at this time.

U.S. LABOR DEMAND RECEIVES OFFICIAL COGNIZANCE

SCARCITY of common labor and lack of workers in the coal mining industry are imperiling all other war production in the United States at the present moment.

A shortage of between 300,000 and 400,000 common laborers exists in the war industries across the line, while the skilled labor supply is also seriously inadequate as evidenced by the fact that one large munitions plant turning out heavy calibre guns is short 2,000 machinists, while the war plants of Connecticut and Maryland alone are undermanned by 35,000 skilled machinists. Immediate relief is sought by assigning the United States Employment Service to act as a centralized government agency in recruiting workers for war work from the non-essential industries as quickly as possible, in view of the amount of work which will devolve upon it after August 1, after which private recruiting for unskilled help for war work becomes effective.

That the machinist's work is vital to the success of the war is shown by the decision of the authorities in the States to ultimately extend the ban to include skilled workers, the mobilization of whom will also be handled by the Federal Employment Service, assisted by the International Association of Machinists, affiliated with the American Federation of Labor, who are putting their whole weight behind the war labor supplying program.

An absence of labor troubles from now on would seem to be likely in view of the fact that deferred classification of all skilled machinists registered in the draft, and furloughs of skilled machinists now in military service are advanced as chief remedial measures.

OUR NEED FOR SHIPS

THE argument has several times been advanced in these columns that Canada must consider the establishment of a shipbuilding industry on a permanent basis if we are to place our products, and particularly our manufactures, in those markets where they can be disposed of to the best advantage. Foreign nations may seek out agricultural products with their own ships but they will want to bring manufactured goods to our shores, not to take them away.

This argument is appealing in the United States in a somewhat different way. In an address before the Illinois Manufacturers' Association, Edward N. Hurley, chairman of the United States Shipping Board, declared that the United States would be in such a favorable position as regards tonnage after the war that it was up to the manufacturers to increase their output so that the ships might be operated to advantage.

If the United States has plenty of ships after the war and Canada has but few it does not take a great deal of figuring to arrive at a conclusion as to which country will be in the best position to develop foreign trade.

SIGNS OF THE TIMES

LABOR and material are the two principal foundations on which organized industry is based. Take away either of these and the other, along with such resultant activities as consumption, distribution, etc., is completely nullified.

This interdependence is proven by the action of the Ford Motor Co., of Canada, the closing of whose factory is attributed to difficulty in obtaining materials coupled with labor troubles.

The universality of the company's products was such that, combined with the known profitableness of its business in the past, its retirement from active business, even though only temporary, is another indication of those changes in business which are taking place slowly but surely, and which have in the course of the past two years brought home to us gradually the present state of world affairs.

That the entry of the United States into the war would have certain far-reaching effects on Canadian industry was admitted by many, but the man in the street has not yet realized the extent to which business is restricted by legitimate measures originating at Washington.

Although Ford cars may not be made in Canada for the present their price does not bring them within the category of banned imports, but the closing of an establishment which has had an annual output approaching 30,000 cars will bring home the true aspect of affairs much more effectively than the prohibition of some particular grade of metal on which comparatively few people ever cast eyes.

CANADA BURNING HER NATURAL WEALTH LIKE A DRUNKEN SAILOR SPENDING HIS MONEY

CANADA is burning up her natural resources and her wealth at the same pace as a drunken sailor spends his cash. Of course the official reports do not put it that way. They state total figures and leave the public to draw its own conclusions.

Apparently Canada is going to lead in a few things, so the Dominion breaks into the head of the procession, and is able to announce that as far as a per capita fire loss is concerned it leads the world.

Something to be proud of and get enthusiastic over, isn't it?

Canada's rate is $2.73 for every man, woman and child. Put the thing in a table so it can be seen and appreciated. It looks like this:—

Canada	$2.73
United States	2.26
England	.64
France	.74
Germany	.28
Switzerland	.13

Well, that's one thing to talk about. We've got the Germans beat ten to one at burning up and destroying property and natural wealth.

Since Confederation

Since Confederation the fire loss in Canada, excluding forest fires, has been $700,000,000. Of this sum $350,000,000 is made up of direct fire losses, $150,000,000 represents the cost of maintaining public and private fire protection services, whilst $197,000,000 is the amount of insurance premiums paid, but not returned to policy-holders in compensation for losses. In addition, nearly 200 people are burned to death and about 500 seriously injured by fire every year. In the four normal years, 1912-15, Canada's annual per capita fire loss was $2.73.

The Timber Losses

Just how great has been Canada's timber loss from fire is not known. It cannot be computed. At best it can simply be guessed at or estimated. British Columbia has paid a great price for having all the fool fire setters loose in that province. The railroads have done a nasty lot of business for that province, but the roads have done a lot better in recent years.

The camper has done his bit to burn up forests and settlements and bridges. There have been campers and prospectors tearing loose over the mountains of British Columbia who wouldn't know enough to eat out of a nose bag when the whistle blew for noon. The experienced bushman, the timber cruiser and the prospector—these men don't start fires. They know all too well what it means. They know the horror of the wall of fire, of the poor meagre chance of beating the fire to a lake or river. They put their camp fires out when they're through and they don't drop burning matches.

A Sorry Spectacle

The foothills of British Columbia bear silent and tragic witness to what fire has done there. Great stretches of timber, the heart and life burned out of it, charred, barren and good for nothing except firewood—and no person is keen for firewood in a land teeming with coal.

The story of British Columbia's forests is the story of Canada's industrial and domestic life as far as fire is concerned.

And the most damning part of it all is that there's no excuse for it.

The best proof of this is actual experience. Take the case of the Massey-Harris plant in Toronto. In 30 years the fire loss has not amounted to $500.

It has cost them something to keep up their own fire department. But they have realized on that investment.

Other Extravagances

And the method of carrying on insurance business is extravagant, according to reports of the Conservation Commission. From 1869 to 1916, the public has paid the insurance companies 65 cents for distributing every dollar of indemnity. This gives food for thought, when it is remembered that, under present Government management, the collection of customs and inland revenue costs less than five per cent. of the receipts. Since the establishment of Government insurance in New Zealand in 1905, the rates on mercantile risks have been reduced 10 per cent. and on dwellings 33 and one-third per cent. The report asserts that insurance agents in Canada are paid, on the average, a commission of slightly over 20 per cent., obviously a large expenditure on middlemen. It is also stated that the number of agents is excessive, a circumstance which makes necessary a higher commission than is economically necessary.

The whole system—pardon the word—of burning up property and carrying insurance in Canada is a long way from being what it should be. There's a grand chance for some good stiff punishment for our fire fiends, and a splendid opportunity for a generous rattling of dry bones.

Preventible fires are nothing short of national robbery, and it's time to call a quick halt to this form of plundering the common storehouse of Canada's wealth.

There's a Heap of These Men

The phrase we hear "grass widower," is a piece of slang, of course, it really means a lonely man, a victim of remorse. His wife has gone, his family, too, to seashore or to stream, or to the country there to sip of honey and of cream.

And Henry John, he stays at home to dwell in single bliss, and murmurs—to himself, of course—there ain't no life like this.

He tells the folks who live next door he is one lonely coon, and he hopes the woman of his heart will hike back awful soon. He sets his table a la carte, he dines in lavish style, he heaps the dishes in the sink—a great and glorious pile.

"The boys" drop in to comfort him, to cheer his weary hours, to help him shuffle up the deck and shake the king and bowers.

They help him wash his woes away with fellowship divine, while Henry brings the wash upstairs in cold and sparkling wine. He helps his guests down off the porch, this man chuck full of sorrow, and hopes they'll be in shape again to go to work to-morrow.

At other times he greets the girls with most profuse salaam, and goes a fierce, blood-curdling pace for a decent married man.

He dons his Sunday meetin' clothes and wears 'em through the week, and smokes cigars and cigarettes until the curtains reek. He leads a whirlwind pace, by gum, this bachelor pro tem, you'd never think of naming him the loneliest of men.

Then once a week he writes a line to the woman of his choice, and tells her he is dying sick for the music of her voice.

He writes an awful hunk of lies, sends kisses to the kids, and says he needs a home-made meal to fortify his ribs. Of course he tells her not to mind about his sorry plight, although he sheds a peck of tears as he thinks of her each night.

But he tells her just to stay right on and finish her vacation, and that for her he'll willingly forget his desolation.

This letter reaches dear Lucille, she bubbles o'er with pity, to think of her dear Henry John a-swelterin' in the city.—Ark.

MARKET DEVELOPMENTS

The Old Tin Can Is Receiving Attention

Restrictions Being Placed on its Manufacture in United States—War Board Insists on Selling Price Being Mentioned in Every Case—Metals Have Advanced in Several Lines During Past Week

APPARENTLY the War Board at Ottawa has decided on the question of price regulation, and events show that they are not to be turned aside by objections on the part of dealers. Orders for release of material from warehouses that do not include in the information the selling price per pound are promptly returned. Apart from that there is not any tightening of the regulations at Ottawa, and the general run of orders get through all right. As a matter of fact it is amazing the number of industries in Canada that are indirectly engaged on war work. Orders for repairs on plants in nearly every case can be traced to war work on either first or secondary contracts, and in this way sufficient warrant is found for passing on the request for supplies of steel or other much-wanted war materials.

United States government is taking steps to spread out the available supply of box tin, and to keep it from being used for anything that can stand aside for the time being. Canners are denied access to the tin market in some cases until the middle of September, and in other lines the canning of certain products is stopped, as it is considered that a sufficient supply is on hand for immediate requirements.

Dealers in scrap metals in a large way are interested in the much-talked of proposal to scrap the railroad running from London to Port Stanley. Any big lot of scrap would be acceptable to the market at this time, although it is debatable if much of the trackage would ever get to the scrap yards, as the demand for rails for re-laying is keen, even for the 60-pound type such as is used in the London road. A mile of such track represents about 100 tons of metal in the rails alone.

There is not much change in the machine tool situation as it has existed for a number of weeks past. Dealers and jobbers are still behind in deliveries of equipment to contractors. The demand for production of munitions is still persistent and continuous. One large Toronto plant has finished the first operation on its British contract, and starts at once tooling for American business. Forgings for this contract, it is understood, will be done in Toronto, so that there will be very little hauling between the point of forging and machining.

Price advances in metals have been frequent during the week, the scrap quotations following on after increases in the other lists. Copper, zinc, lead and antimony have all increased.

SHIPYARDS AND MUNITION PLANTS ARE LARGE BUYERS OF MACHINERY

Special to CANADIAN MACHINERY.

MONTREAL, July 9.—Munitions and shipbuilding vie with each other in supremacy of industrial activity. The recent announcement that larger output of shrapnel was desired has stimulated the shell industry, and owing to the reverting of the smaller tools to the production of the 75 m.m. American shell the demand for such equipment has been increased. During the past week the shipyard of Fraser, Brace Co. floated two of the four 3,000 tons wooden vessels, now under construction. Considerable local interest has been shown in the relaxation of priority certificates for steel, but the situation is still one where little surplus steel is available for other than essential needs. Contrary to expectations the price of copper has been advanced to 26 cents. as a result of freight advances and higher cost of production. Machine tool activity has recently increased following the placing of shrapnel orders.

Pig Iron Stronger

As a result of the higher cost of transportation and other conditions the situation has become stronger at the new price recently fixed by the governing board. The 45 cent advance is now effective on Pittsburgh iron, Bessemer being quoted at $36.60 and basic at $33.40 per ton; No. 2 foundry is now $34.40 per ton. Local conditions are unchanged with little iron available for the market, as a consequence no quotations are available.

Steel Unchanged

Although it has been that the priority regulations have been somewhat relaxed, the situation here will not be influenced to any great extent, as the conditions will remain practically the same. As one dealer puts it the priority contracts now at the mills awaiting fulfilment are ample to keep the producers busy for the next six months, so that it will be very small volumes of material that will be available for disposal under the open selling basis. Should operations warrant a continuance of this ruling it would likely be some time before the relief would be felt here. Dealers, however, report improvement in the delivery of steel from the States, but the possibility of securing early shipments of material ordered now appears to be as remote as ever. Semi-finished steel producers are now negotiating with the War Board with the object of arriving at an agreement for revision of fixed prices. Early announcement may be expected in this connection. The market is still one of government requirements and prices here are firm and unchanged.

Metals

The strength of the general market continues and the demand has been steady. Due largely to the higher cost of transportation the prices on some of the metal show a stronger tendency. Copper prices have been revised, tin is unsettled but has declined locally. Spelter is higher under increased demand. Lead has also advanced. Antimony and aluminum are steady and unchanged.

Copper.—The recent action on the part of the U. S. War Industries Board in agreement with the producers, in advancing the fixed price on copper, came as a sudden surprise to the majority, as it was not anticipated that a departure from the old price would be adopted at this time. The uncertainty that has prevailed for the past few weeks as to what attitude the government would take regarding a new price has created a situation that will require some attention before the market can resume a normal tone. Sales that have been made recently for future delivery will necessitate some revision owing to the changed conditions. Buyers may wish to hold the producer to the former price, while the latter may claim the higher price just fixed. However the market or government price of 26 cents will be the basis for the next period's operations, but it may be some little time before normal trading is established. The local demand continues steady but not heavy, and metal is hard to get. Dealers have advanced prices to 30 and 31 cents, this being one cent higher than the quotation of last week.

Tin.—Some relief has been shown in the tin situation but the market is still an uncertain one. Further restrictions have been placed on export of metal from England and the tension here is still pronounced. New York quotations are normal at 92 cents per pound. Dealers here report a better supply with the demand good. Prices asked are easier, a fair average being $110 per hundred; this is 15 cents per pound lower than a week ago.

Spelter.—Interest in this metal has revived as a result of the activity that has recently been displayed by heavy trading in the States. Brass interests are good buyers and the general demand shows improvement. Dealers here quote 11 cents, an advance of ½ cent per pound.

Lead.—Coupled with the advance in American freight rates, the renewed demand for shrapnel has increased the strength of this metal and higher prices are in order. The American trust price is on a par with the open market, the nominal quotation being slightly over 8 cents per pound. Local demand has improved and an advance of one cent places the current price at 10½ cents per pound.

Machine Tools and Supplies

Considerable activity is still evident on every side and the demand for shell making machinery continues to be a characteristic feature. The requirements for the 75 m.m. shell and also the British shrapnel are quite heavy and shell makers are active buyers of used machinery. One firm here which is erecting a new plant to take care of additional business on the American .75 are expecting to obtain equipment in the near future from a plant specially organized to construct the tools required. Dealers report enquiry in excess of the supply and delivery in many cases behind schedule. This also applies to considerable of the accessories that are used in large quantities in munition factories. Shipyards are still good buyers, particularly in the way of the smaller tools, such as air-operated tools, etc.

Scrap Unsettled

Dealers report a quiet situation with little trading. Some business is being done for immediate requirements but future business is dull. Prices are uncertain but unchanged.

POINTS IN WEEK'S MARKETING NOTES

It has been found that in some cases U. S. jobbers had large stocks of steel on hand, which they had been accumulating for years, and holding for fear of running out of certain sizes.

—

Advances are noted to-day in several lines of scrap metals, especially coppers. The action of U. S. in raising the price for electrolytic is given as the cause.

—

The War Trade Board at Ottawa adheres to the ruling of having the selling price stated on all orders released from warehouses. Orders where this is omitted are promptly returned.

—

Orders for boiler tubes reaching Toronto this week are on a scale large enough to clean out most of the local stocks.

—

U. S. prohibits manufacture of condensed milk as a measure to conserve the supply of sugar.

—

Cans cannot be supplied to preserve beans until the 15th of September. This will release thousands of boxes of tin plate in the next two months.

—

Dealers in scrap in Toronto are waiting for developments in the proposed scrapping of the London-Port Stanley road. The rails there should run about 100 tons to the mile, but the chances are they would never be sold in as scrap.

WAR BOARD INSISTS ON PRICE MATTERS

Orders With This Information Left Out Have No Chance to Get Past

TORONTO.—There are firms entering the market to-day for steel, machinery and supplies, and who are now receiving every consideration in the way of preferred treatment, that a year or so ago were not considered to be of much account. In fact some accounts that were begging at that time are now looked upon as good business to handle. The war has practically put them on their feet. And there's quite a chance of a number of these establishments staying in business after the war ends.

But the war and business connected with it continues to be the centre of all deals put through on a large scale now. There are big concerns in Canada now — big enough to rank as right at the top, whose output is at least 85 per cent. on a strictly war basis. The phrase war basis provides a much larger place to work in than might be imagined at first.

There are some disappointments going the rounds in the matter of securing deliveries for promised war purpose machinery. The strike of the moulders a little while back hindered the work in some cases, and other causes have all tended to retard the work. The contractor for shell work who is getting delivery of his equipment on time to allow him to live up to his delivery schedule is a fortunate person.

Advances, quite sharp in some cases, are noted this week in the prices offered for copper scrap, either light, crucible, heavy or copper wire. The reason assigned is the action of United States Government in advancing the price of No. 1 electrolytic copper from 23½c to 26c.

Price Regulation

The War Trade Board at Ottawa is standing pat on its determination to find out the values at which material is passing under permit from the Canadian warehouses. In a few cases orders have gone forward to Ottawa without the blank for the price being filled in. Invariably these orders, although of the war preference sort, are returned at once. Dealers in the great majority of cases show a tendency of playing square with the War Board. They state the price at which they are selling exactly according to facts. "If the War Board decides that we are doing business on too large a margin of profit," declared one dealer to-day, "it will probably give us a chance to get together on the proposition and get our case in the right light at Ottawa." As a matter of fact there is little complaint about orders being turned back from Ottawa. Dealers weed them out before they go through, but even at that there are not as many refusals from Ottawa as there were a few months ago.

Using Large Amounts

Orders placed this week at Toronto for four-inch boiler tubes are large enough to well nigh make a record. Some of them are well into the carload size. The establishment of chemical works here on a fairly large scale, and the nature of the business they are carrying on, means that there will continue to be a large and insistent demand for tubes. In fact it is doubtful if there are many tubes left in Toronto warehouses right now. Buying is becoming increasingly difficult but in spite of that there has not been a tendency to chase the prices up, as it has been a number of weeks since an advance has been recorded in tubes.

Securing Equipment

As the volume of American business being placed in Canada increases there is a noticeable increase in the number of American firms looking for business in Canada. One large Toronto shop that has turned out an enormous number of the six-inch shells on British order is clearing up the last of the work on this. In fact the first operation has been suspended, and the work of tooling for the 9.5 will be undertaken in the course of a few weeks. Forging for this machining is expected to be carried on in Toronto. The American Government is apparently ready to give reasonable encouragement to Canadian firms with good reputation, preferably those that have done well in turning out satisfactorily work on Canadian and English orders. Advances of considerable amounts have been made in several instances. The idea behind it all apparently is that it is the desire of the U. S. Government that production shall begin as soon as possible, and Canadian contractors shall not have to hold back in the rushing through of the work for lack of available funds.

Scrap Metal Situation

Several Toronto firms are awaiting for further developments in connection with the proposed scrapping of the railroad running from London to Port Stanley. In fact Toronto dealers have looked the proposition over several times, and seem to be standing back now waiting for the next move on the part of the London people. As a matter of fact it is hardly likely that the rails there will ever come into the scrap market, although they would be very acceptable. But for re-laying purposes they would bring a higher price than scrap, and it's money that will determine such a matter, as well as the need for rails, although they are of the 60 pound sort. In a mile of such track there would be about 100 tons of metal.

Prices on several lines of metals moved up this week. The lines affected are light copper, crucible copper, heavy and copper wire, new brass turnings and red brass turnings. The increase is one cent per pound. United States government has placed the price of No. 1 electrolytic copper from 23½ to 26c., and the prices of scrap are trailing along in the same direction. There is a tendency in some circles to buy heavy on copper in anticipation of further advances. Dealers are not anxious to strip their yards on this tendency until they see exactly what the future is going to hold for them in the way of restocking chances.

More Advances

There have been increases noted in many lines of metals during the week. All grades of copper are up. Lake copper and electro copper are quoted at 29½, and copper castings at 28½.

Tin still moves around the $1.25 mark. The tin market is a peculiar thing just now. United States government is taking some rather drastic steps in order to spread out the available supply of box tin. Certain canning factories are shut off while until late in the season, and it is not permissible to can certain brands of milk, as it is considered that there is a sufficient supply of this on hand to last for some time to come. High prices bring very few offerings to the market, and the fact that a certain figure is named is no indication that a sale has actually taken place at that point. Yet, notwithstanding all this, there are no concerns that we have heard of that are pinched hard in this country for a supply of tin. Prices are sky high and there's not much to be had, but it hasn't come to the point of real hardship yet.

Spelter advanced quite sharply also and is now on the list at 11c. Lead, antimony and aluminum are also among the prices to advance.

CONTROL OUTPUT OF MACHINERY NOW

U. S. Government Takes Another Step Towards Having Situation Well In Hand

Special to CANADIAN MACHINERY.

NEW YORK, July 10.—Greater control of the machinery industry is being taken by the Government, the latest phase being the reference of all orders for travelling cranes to the War Industries Board before final action may be taken. Representatives of crane builders in New York this week were notified that a decision had been reached by the Government to control the manufacture as well as the sale of travelling cranes. It will be recalled that a Government Committee at Washington already has supervision over all orders, prices, and priority shipments of locomotive cranes and it is expected that the same method will be used in dealing with travelling cranes and possibly with other conveying machinery.

As a result of this action the Bethlehem Shipbuilding Corporation has submitted the orders which it was about to distribute for 100 travelling hammer-head and tower whirley cranes to the War Industries Board, but it has placed large orders for fabricating machinery and for machine tools calling for the expenditure of several million dollars, which together with the cranes are to be installed at the Liberty ship plant at Alameda, Calif. The Bethlehem Corporation has also asked for bids on fifty machines to be installed in extensions now being made to its Sparrow's Point (Md.), shipyard.

Other large inquiries for conveying machinery are in the market including 94 hoists for the Johnstown plant of the Cambria Steel Co. For the Baltimore & Ohio Railroad locomotive shop at Cumberland, Md., the Westinghouse, Church, Kerr & Co. have bought more cranes, and are negotiating for machine tools and for fabricating machines. The Pennsylvania Railroad Co. is preparing to buy cranes and machine tools for a new locomotive shop at Marietta, Pa.

Several shipyards have either bought or are in the market for cranes including the Federal, the New York Ship and the Downey Shipbuilding Corporation. The Navy Department is inquiring in the

HE CAN'T SEE WHY MACHINE TOOL BUSINESS SHOULD SLUMP AFTER WAR

Dealers in machine tools and supplies are fond of discussing the chances of their business when peace is declared, and in the period immediately following the war. The most of the dealers are up to their necks in business at the present moment. This applies to jobbers as well as to the makers of tools.

"I can't see where the business is going to have much of a slump following the war," stated one well-known manufacturer recently. "When you look at the way the machinery has been run, at the way in which much of it has been thrown together, and then consider that a great deal of it is single-purpose machinery, you will see that I am right in the views I have on this matter.

"You must remember," he continued, "that there has been a tremendously big element of haste in all this war work, I don't say that the work has been slopped over, but I do contend that there has been such a rush for machinery that it has not been built up to the standard of other equipment turned out in normal times by the same shops. Then this one operation day and night plays the deuce with a machine. Put a lathe, say a turret lathe for instance, on rough turning for a long time, three shifts every twenty-four hours, and let it stay there, with all the wear, tear, pressure and grind right down the one channel, and you are going to have a machine that after a year or so is not going to do other work nicely for you. That is a point that others may dispute, but I am speaking from actual observation and experience in war plants since this war started. Then on top of that remember that a great deal of the equipment that goes into plants now is single-purpose machinery. When it gets through turning out the contract on munitions it is good only for the scrap market, unless some person gets busy in the meantime and scares up rumors of another war that will call for the production of shells. I can't see where the machine tool business is due for a slump after the war. It seems to me that there is going to be a great big demand for good machinery, and that this demand will extend to a great many lines that have been practically standing still since the outbreak of the war."

Philadelphia market for 58 lathes and another list has been issued for Charlestown, Mass., delivery.

Steel Bars Wanted

There is a very heavy demand for shell steel bars from the Government, especially for the sizes used in manufacture of 75 mm. gun projectiles, but most of the mills rolling shell bars have capacity sold over the next four or five months and some of the large rail mills which have been rolling shell bars are preparing to return to the manufacture of standard section rails for the Railroad Administration, which has called for practically 2,000,000 tons to be shipped this year. Two companies in the Philadelphia district are preparing to manufacture 8-inch semi-steel shells and have issued tentative inquiries for machine tools. The American Shell C., Paterson, N.J., has bought additional equipment to increase production of 75 mm. shells. The Kokomo Steel & Wire Co., Kokomo, Ind., having received a shell contract from the Government will spend $3,000,000 for new buildings and machinery to enable it to execute the contract.

The Western Cartridge Co., East Alton, Ill., is preparing to triple its production and will need additional equipment. The Otis Elevator Co., Chicago, has bought additional equipment for its plant where it is making recoil gun mechanisms, and the Four Lakes Ordnance Co., Madison, Wisconsin, is buying additional tools to increase production of guns.

Want Equipment

Several steel companies are in the market for additional equipment and one list of machine tools has been issued for a plant in the Shenango Valley, the Atlas Crucible Steel Co., Dunkirk, N.Y., has bought cranes and the Midvale Steel & Ordnance Co. is still negotiating for machinery for its new gun plant.

Under the auspices of the United States Shipping Board, the purchase of 52 acres of land has been made at Birmingham, Ala., upon which to erect a fabricating shop to serve shipyards in the South, especially those at Jacksonville, Fla., and Savannah, Ga. The steel plate will be furnished by the Bessemer and Fairfield mills.

THE PRODUCTION OF COAL CONTINUES TO DECLINE IN MARITIME PROVINCES

Special to CANADIAN MACHINERY.

SYDNEY, N.S., July 10.—A settlement of the wage dispute between the Nova Scotia Steel & Coal Company is announced, an agreement having been reached by the company granting a small increase in wages to the men who were not affected by the findings of the Royal Commission. The workmen of the Dominion Iron & Steel Company are also dissatisfied with the findings of the Commission, and the company has offered an increase to the higher paid men, which has not yet been accepted. Some of the more strongly organized unions, such as the bricklayers and moulders, are not satisfied with the increase offered, and are demanding wages and working conditions such as exist in urban centres in the United States and in Ontario. There is a tendency among the skilled trades to endeavor to introduce union rules and conditions, a tendency that is bound to come into conflict with the management of large operations employing a great number of men, such as steel works. In industrial operations of such magnitude and complexity it is difficult for the management to deal individually with all the specialized trades that are represented on the payroll, or to recognize any differentiation in worth or status among employees, whose activities, while they may differ in detail, are really part of one general manufacturing process. This phase of the labor question is bound to cause some friction sooner or later. It is not expected that any stoppage of work is likely to take place at any of the Nova Scotia steel plants at this time and it may be confidently anticipated that a general settlement of all outstanding labor questions will shortly be reached.

Coal Output Declines

The coal output continues to decline. For the first six months of 1918 the production has fallen off from the record of the first six months of 1917 by about 330,000 tons, and it is only too probable that by the end of the year the total output will be less than those of 1917 by almost half a million tons. At the same time it is hoped the rate of decline in the last half of 1918 will not be so rapid as it was during the last six months. That is the best that can be hoped for.

The same tendency is to be noted in the production of bituminous coal in the United States and in Great Britain, and to those who know the situation the problem of coal production is not the least among the problems that face the Allied leaders. If the coal production declines to a point where it restricts the output of munitions and the transport of troops, the gravity of the situation will appear in its true light, and things are approaching such a point. The hardships which may be inflicted on private consumers by a shortage of fuel in Winter appeal most strongly to the man in the street, and the efforts of the Fuel Administrator in the United States and the Fuel Controller in Canada have been directed towards the amelioration of the condition of the domestic consumer, both as to price and quantity. But the operation of war factories, the transport of men and supplies, and the general operation of the machinery of war depends entirely upon coal. If these activities are touched, then the private consumer will have to freeze,, if need be. because the grim actualities of war will compel that the needs of the army and the navy shall come before the requirements of the people at home. It is not pleasant to perform the work of an alarmist, but it is all too certain—whether the war continues or not—that there will be a shortage of coal throughout North America next Winter much more severe than was experienced last Winter.

The excavation of the site of the new plate mill at Sydney is proceeding vigorously.

TAKING MEASURES TO SAVE TIN PLATE

U. S. Has Stopped Supply to Bean Canners and to Condensed Milk Plants

Special to CANADIAN MACHINERY.

PITTSBURGH, July 10.—Practically all the steel produced is still going out against Government orders or against the preference schedule of the more essential purposes for which steel should be used at this time. Any steel that might remain after the priorities and preferences were satisfied would be available for general distribution, but only under permission granted by the Directorate of Steel Supply. That there will be such a surplus eventually is commonly believed, but not until the present rate of shipping steel to the war activities causes them to call for a reduction in their quotas. The object of the present regulations is to cause stocks to accumulate in connection with these activities, particularly shipbuilding and shell making.

While the control of steel shipments is very rigid as to its general scope and purpose, there are increasing evidences that the War Industries Board does not intend to permit the industries that are not accorded any preferential treatment by the present regulations to suffer any unnecessary hardship. It is intimated that there will be relaxations from time to time to permit important business to go ahead provided it does not interfere with the main object of winning the war. The immediate reference is to manufacturing consumers, in the less essential industries, who have some stocks of steel on hand, but require some additional sizes or descriptions of steel in order to utilize that on hand.

Stocks of Steel

The fact that steel has been decidedly scarce for nearly three years should not be taken as proof that there are no stocks in the hands of buyers at the present time, for as a matter of fact the reverse is the case in many instances if not in the majority. What has been called a "scarcity" of steel for more than two years has not been a famine, but rather a difficulty in securing prompt deliveries, and unusual delays in securing deliveries of some sizes or descriptions. The natural result of this condition has been to cause jobbers and manufacturing consumers, as a measure of protection, to seek to pile up stocks so that they would be safe from loss when there were delays. It was not so much a scarcity of steel for the immediate requirements of the buyers, but an inability to obtain as much as was desired. It is the testimony of an authority quite familiar with the position of jobbers that in the main they have to-day heavier stocks, in point of tonnage, than they had two years ago. and yet the jobbers have been urging the authorities to devise a system of preferential treatment for them, particularly along the line of enabling them to replace freely any steel that they sell for direct or indirect war purposes. Many cases are arising of manufacturing consumers who seek assurance of future supplies when it turns out that they have stocks to last them for some time still, frequently for a couple of months. By the time these buyers really need any considerable quantities of steel there may be a fair supply available for them, and as already indicated the Director of Steel Supply is likely to accord small tonnages of steel to those who already have a considerable tonnage, but need some extra steel in order to round out their stocks. In this connection the director is naturally influenced by the fact that this will enable business to go on, keep money in circulation, and produce profits out of which taxes can be paid.

Sales and Deliveries

There is an interesting difference in the interpretation of the regulations by some of the producers. The majority of producers interpret the regulations as applying to deliveries only, thus permitting sales to be made irrespective of the use to which the material would be put if delivered, there being of course no guarantee when the sale is made as to when delivery will occur, if ever. Other manufacturers insist that the regulations do not permit them to make sales except of material the delivery of which is provided for by the regulations. As to deliveries there is practically no difference of opinion, the regulations being quite well understood and being interpreted substantially alike by all interests. As a concrete illustration, the American Steel & Wire Company adheres to the policy announced in its recent circular, of accepting business freely from its regular customers for delivery whenever this becomes feasible. Very nearly all, if not all, of the independent wire producers adhere to the policy of not accepting business from ordinary commercial buyers who are not accorded any preference treatment in the matter of deliveries. They do not deny that matters may eventually so shape themselves that the deliveries will be possible, but they maintain that when all mills are filled for about three months to come there is no use in booking additional business at this time unless it is of the kind that is accorded preferential treatment.

More Tin Plate

For the purpose of conserving sugar the Food Administration has issued an order prohibiting the manufacture of condensed milk. Evaporated milk is not included as it does not involve the use of much if any sugar. There are large stocks of milk in existence and further accumulation is quite unnecessary. This procedure will release a considerable quantity of tin plate. Another order has been issued affecting the supply of tin plate, restricting the packing of dried beans until September 15. The can manufacturers are not permitted to supply cans to the industry until the date mentioned, and tin plate makers are not allowed to supply tin plate to the bean packers who make their cans. Special exceptions will be made in case of lots of beans showing so much moisture that they might not keep. It is estimated roughly that the two orders will release, for other purposes, about a million boxes of tin plate in the next two months, and some of this may be available for increasing exports over the provisions already made. The tin plate mills expect to produce regularly about three and a quarter million base boxes of tin plate a month during the remainder of the year, and this will bring the calendar year's output to fully 36,000,000 boxes. Arrangements were recently perfected whereby each tin plate plant will be fully supplied with steel. Each plant is rationed with so many tons per week per mill. The only weakness of the system, as viewed in the trade, is that the only proviso against an accumulation of steel at a plant that has lost time or has otherwise failed to consume steel at the scheduled rate is that the plant is expected to report any accumulations that may occur and some plants may neglect to make such reports.

STORAGE OF COAL

Some notes on the storage of coal with reference to the prevention of spontaneous combustion were given by Mr. John H. Anderson before the Institute of Marine Engineers, London.

The author said that his remarks were based in particular on experience gained with a heap containing just over 16,000 tons. The heap consisted entirely of small bituminous coal, of several kinds, washed and otherwise, some being of a character supposed to be dangerous for storing. Under these conditions extra care was exercised. Temperature readings were taken at 14 different places nearly every day, and occasionally also at the vent pipes, of which there were 50. Further, to find the hottest part, readings were taken at every foot from top to bottom at certain places. Previous experience indicated that the warmest place was between 6 ft. and 8ft. from the surface; hence 7ft. was established as a standard depth for temperature records. The temperature tubes were ¾ in. or 1 in. gas tubing, driven in from the top to the bottom of the coal and long enough to project 2 ft. or 3 ft. above it. In most cases the vent pipes were old scrap tubes about 8 ft. long and 3 in. or 4 in. in diameter, and were driven down to the 7 ft. mark, their ends being flattened, chisel-shape, to facilitate driving.

By taking periodical readings of the temperature of the pile and comparing them with previous readings ample warning was obtained to prevent a fire. If a readying of 90° F., which was adopted as a warning temperature, was obtained at any place four other temperature tubes were driven down north, south, east and west about 10 ft. from the warm tube. The tube which gave the highest reading next day was then made the centre, and other pipes put down in its direction, the idea being to locate the source of heating. When the warmest place was found an additional vent pipe would be put in there, and this generally arrested the rise of temperature. If, however, it did not, a trench was dug a foot deep on each occasion—that is if the readings remained at, say, 100° for three days the trench would be 3 ft. deep. In fact a temperature of 100° was never reached, but on four occasions, when 95° was recorded at a point where the coal was deposited to a depth of 16 ft., a trench was dug. Probably, however, this trenching would have been unnecessary had additional vent pipes been inserted. If a fire occurs, although plenty of water should be available to quench it, it is better to dig all round it, and if possible remove the hot coal.

In general the depth of the heap should not exceed 12 ft. to 14 ft. for small graded coals, or 9 ft. to 12 ft. for unwashed mixed coals. As regards slacks, a good deal depends on the composition. The author allowed two heaps of this material 10 ft. deep to rise to 120° before moving them, and they gave considerable trouble; even when they were reduced to 6 ft. there was a tendency for them to increase in temperature. Anything, such as pieces of wood, pit props, rags, waste, shavings, and straw, that ignites at a lower temperature than the fuel should be kept out of the heap. As a rule the greatest danger is up to about three months from the time the coal is taken out of the pit.

NEW POWER STATION AT GLASGOW

The total power capacity of the new electric power station now under construction at Glasgow, and to be opened next year, is 150,000 kilowatts or 200,000 horse-power. The central station is at Dalmarnock, and electricity will be transmitted at a pressure of 20,000 volts (three-phase alternating 25 periods per second) to distributing centres in other districts of the city.

A site measuring 13½ acres has been taken in hand bordering the River Clyde, and an ample supply of condensing water is obtained from that river. The first portion of the works already completed comprise a water intake, a screening house, two water culverts, switch house, turbine engine room, two boiler houses, workshop and store, and a complete coal-handling plant capable of dealing with 100 tons of coal per hour. The cost of this coal plant is £24,800.

The first instalment of the machinery will consist of three 15,000 kilowatts (20,000 horse-power) turbines, which will be coupled direct to alternating current generators; also three 1,000 kilowatt (1,300 horse-power) turbo sets for driving auxiliary machinery. It is proposed to add plant units of 15.000 kilowatts as the demand increases, while turbines of 30.000 kilowatts can be installed if found to be necessary.

Some Considerations Regarding Modern Plant Organization--7

By M. H. POTTER

The factors which enter into the successful manufacturing business of to-day are interdependent to an ever-increasing degree. Location, type of building, transportation facilities, staff organization and plant equipment are features which require to be considered both singly and as a whole in relation to the particular product to be undertaken. A clear and concise idea of such considerations is necessary before entering any one line of manufacture.

CORRESPONDENCE

THE discussion of that most important phase of a business house's outside relations—its correspondence, falls under two heads: (1) Incoming mail and (2) outgoing mail.

1.—Incoming Mail

Every transaction handled by a business house, except cash sales, must sooner or later be dealt with by the correspondence department, and to facilitate and simplify the methods of conduct and of keeping records is the first aim in organizing this department. Above all, simplicity, combined with accuracy, is to be desired, as a system is useless in which a letter is filed away so elaborately or carelessly that it can never be found again.

The head of the department is responsible to the business manager. He has charge of the following duties, performed singly or in conjunction with persons under him:

1. Disposal of incoming mail.
2. Stenographic correspondence, etc.
3. Mailing.
4. Filing.

In a large business a central room or mailing department is the most satisfactory and convenient way of handling mail. Hence all incoming and outgoing mail should be received. Telegrams should be received and signed for in this department and delivered to the person or department for whom they are intended.

Treatment of Incoming Mail

The letter carrier should deliver to this department all the mail, taking receipts here for registered and special delivery letters and collecting postage due.

The mail should then be carefully sorted by the head clerk of this department or one of his assistants, the personal mail being separated from the company's. Personal letters are delivered unopened. Individual letters addressed conjointly to the firm are delivered to the head of the department in which the person is located. Letters of importance go to higher officials. Routine letters are passed on to the regular correspondents. The company's mail should be handed to one or more clerks to be opened, they in turn passing it to others to remove the contents. Clerks should be very careful to pin all enclosures to letters to which they belong. The mail is then passed on to others, who apply the receiving stamp. It is better to stamp all mail on the back to avoid disfiguring the face of the letter. When stamped the head clerk should note the department to which the letter belongs and place it in a basket or pigeon-hole of a case marked with the name of the department. When the mail is all sorted, according to departments, it is delivered by a boy to the respective departments. A convenient way to carry the mail is in a strong leather bag divided into compartments, marked with the name of each department.

If firms, when writing on different subjects, would write one letter on each subject and address it to the department in question, it would simplify the delivery of mail very much, and also insure its going direct to the department to whom it belongs. Much time would be saved in delivery and possibly misplacement or loss of letter avoided. Reference should be made to the person whose letter is being answered. Very often a letter merely addressed to the company will go the rounds of all the departments for a day or two before it is finally claimed by the person to whom it belongs.

The distributing of incoming mail should be, of course, in the hands of a thoroughly reliable person, familiar with the names of the persons connected with the company and the matter handled by the various departments.

To facilitate filing and also keep a clear memorandum, of the business on hand the clerk might note on small cards the business of each letter, the department or official to whom it is sent, or any other special remark. Such cards can be attached to their respective letters, and when returned in the evening would be endorsed with the action taken and then filed, furnishing a complete record of the transaction.

Personal Letters

Personal letters sent to employees in care of the firm, or business letters which are addressed to the employees individually, should be discouraged. In the first instance, such mail only clogs up the machinery of the office. In the second, important matters may be delayed on account of the absence of the person to whom sent. Many business houses now print above their stationery a request that letters pertaining to the business should always be addressed to the firm.

Stenographic Correspondence

After letters have been received, distributed, and read, they remain to be answered. In some cases the heads of the business have their own private secretaries, but the general bulk of the correspondence is undertaken by a staff of stenographers, under the supervision of a chief stenographer. It is usual to have the stenographers in a room separate from the rest of the office. Calls for stenographers are sent to the chief, who selects one of his staff according to the amount of work he or she has got at the moment, and so arranges that stenographers are not confined exclusively to the services of one department.

It is the duty of the chief stenographer to see that the mechanical qualities of the letters sent out are perfect; that care is given to spelling and punctuation, etc., and that the work is done promptly.

There are several ways of keeping supervision upon the work of individual stenographers. Probably the best is that in which the chief stenographer, in sending a stenographer to take letters, gives him or her a daily card, which is to be filled out with: (1) Stenographer's name; (2) dictator's name; (3) time of taking notes; (4) time of transcription; (5) number of letters. A duplicate is kept by the chief stenographer, who files it, and from that source can make up a weekly statement of work done by individuals. The stenographer in transcribing her notes makes carbon copies of all letters. The letters are sent to the proper department or person for signature, while the carbon copy is attached to the letter to which it is a reply and is ready for filing.

Filing

The object of filing is to keep an easily available record of correspondence, and it is important that it should be in the hands of careful operators. Filing may be done according to four methods—alphabetical, geographical, numerical, and by subjects—these having been generally accepted as the most efficient. Whatever system is employed, care should be taken that all folders and drawer files are of standard size. The letter is first placed in a folder, and the folders are put into vertical drawer files, the divisions or grades being of cardboard, the tabs on which are a trifle higher than those of the folders. Each folder should bear the name of the department to which the filed letter refers, and be filed in front of the guide for that division.

Alphabetical

When the correspondence is small, this is the most usual form. The guides are printed with the alphabet in sub-divisions. Firms with which a large correspondence is carried on should have a separate folder. In the alphabetical system the correspondence is filed alphabetically under the name of the correspondent. Though not absolutely necessary, an auxiliary card index will often be required in the alphabetical file also, particularly to locate letters signed by individuals, but filed under the names of the concerns whom they represent. Letters from infrequent correspondents go into a miscellaneous folder.

Geographical

The geographical system is adaptation of the simple alphabetical system of a very large business. In this system the primary divisions of the catalogue are geographical ones, usually the provinces. If desired, these are still further divided into cities. The matter is filed alphabetically under the names of the correspondents residing in each geographical section. In firms which have a large staff of salesmen on the road this method is to be preferred.

By Subjects

In the index by subjects all papers relating to a given subject, irrespective of the names of the correspondents, are filed together. This method is rather unusual, and only used by manufacturers or manufacturers' agents who make or distribute many varieties of articles. Here the guides bear the name of the articles, and the folders the names of the various materials. A cross index is usually necessary under this system, to make sure of finding a letter without difficulty.

Numerical

This method is usually resorted to by houses which have a large mail from regular correspondents, and is much used in advertising departments. In the numerical system each correspondent is assigned a number, under which all his correspondence and all papers relating to him are filed. In this case the guides are numbered by tens, increasing consecutively, the folders bearing unit numbers. One folder is given to each house, and in cases where the correspondence overflows additional folders bearing the same number may be filed alongside. As naturally the system of numbers gives no clue by itself to the names of the correspondents, there should be an accompanying card-index, the cards of which have the name of the firm, address and file number, with cross-reference cards, and in some instances another color for the individual members of the firm, both sets referring to the same folder.

The files should at all times be kept in perfect order, and no one should have access to them but the filing clerk or clerks. All letters should be removed only by such clerks, and should be returned promptly. To insure their return a memorandum should be placed in their stead in the file. Once or twice a year letters are transferred from the current files to stored filing cases. There should always be at least six months' correspondence in the current files.

Tickler File

When a letter is to be taken up or followed up at a specific future date two carbon copies are made, one of which is filed with the correspondent's letter, the other being placed on the tickler or reminder file, the guides of which are labeled according to date. The memory is thus jogged at the proper time and no small detail is forgotten. The file is kept in the ordinary filing department, but each correspondent has a desk file of his own covering the correspondence with which he is concerned. Letters to branches, which are frequently inquiries, should have a blank space thereon for replies, the original being used. When this is returned to the inquirers it is, therefore, complete and reference does not have to be made to the copy.

Outgoing Mail

Letter writing has always been one of the fine arts, but it is only within recent times that any attention has been paid to business correspondence. Although personal writing is being driven back by the telegraph, postcard, and telephone, letter writing in business is day by day being advanced to greater efficiency by the introduction of the personal element.

The Outer Form of a Letter

Business organization has this fatal faculty, that it conduces to mechanical adherence to certain well-established rules. The letters of one firm imitate those of another or of all until correspondence becomes a series of set phrases. Forms become stereotyped and language either too bald or too prolix. A letter may be written more or less vague on stationery which is an eyesore, clumsily crushed into an envelope half-opened and insufficiently addressed. It is allowed to leave the office not alone, but in the company of equally faulty mail matter. And the harassed head of the business, seeing the balances dwindling, wonders why, with the best salesmen, an organization almost perfect and goods all that he claims them to be, his rival outstrips him in the race. As a hint he might well look at the correspondence methods of his rival.

The company which prides itself on its standing will make a special feature of its letter writing, with careful attention to every detail of form, typing, and stationery. Nothing is too trivial to be overlooked. A man might as well go out to a reception with his clothes unbrushed as send out slipshod letters.

Letter-Heads

The letter should be engraved or lithographed. If type is used it should be simple and bold. Occasionally lettering may be printed from the line block. Bright colors should be avoided. It is better to use black. The trade mark may be introduced, but it is out of place. The letter should include:

1—The name of the individual or firm.
2—The address.
3—Department of issue to which replies are to be addressed.
4—Telephone number.

It might also display the names of the officers, cable address, foreign branches or agencies, and nature of business. But care should be taken not to create confusion by overloading. The less space used the better. Advertising should rarely be permitted to enter into a letter-head. It is not the proper place for it.

Printed Matter

Take a few minutes and glance over the stationery you are now using. Is it good printing? Does every letter, rule and other characters stand out clear and sharp? Or are the characters broken in places, with scarcely enough ink? Look on the back of your letter-heads, etc. Are the letters and rules piercing through, so that they can be plainly read from the back of the sheets? Are the sheets marked on the back with offset, or smeared with ink? If any of these defects are noticeable the work is not good enough. Insist on the use of some of the latest, clear-cut type faces. Where printed forms are used largely in the mechanical departments of a factory stock reports, time sheets, memo. blanks, etc., it is the experience of every business man that the heads of the departments frequently make use of the last sheets before ordering an additional supply. To prevent delay the printer should be instructed on receiving an order for the blanks to place in stock and hold until the next order two or three pads of one hundred sheets each of the work in question.

The business man can prevent considerable waste in printing by ordering all sheets, forms, blanks, etc., tablated in pads of one hundred sheets each. The sheets do not then become scattered or soiled, and are more conveniently handled in the mechanical departments.

Envelopes

The envelope should be printed in exact conformity with the accompanying letter. Thus if the name of the department appears in the enclosure it should appear on the front of the envelope also, in the left-hand corner. If delivery is not made, the envelope will thereupon be returned without delay to the proper quarter. A small matter, but one of the many which go toward making up a good impression, is the folding of the letter. The folding of the sheet should be carefully done, so that on opening the envelope the first thing to be seen is the firm name in the heading.

Typewritten Letters

Much depends upon the make-up of a letter. The type should not be smeary, and erasures should be avoided. Group your type lines symmetrically and even up your margins. If you have a short letter set it in the middle of the page. Don't crowd it up at the top. Indent your paragraphs, and if you want perfect clearness leave space between each.

Contents of a Letter

Every letter should contain six things:

1—Day, month, year.

2—Name and address of person to whom sent.

3—Opening salutation, sir, etc.

4—Body of the letter.

5—Complimentary ending, yours truly, etc.

6—Signature; if typed, followed by signature of official.

It has been said that the business letter, as representing an agent, should be couched in language as much like that of conversation as possible. This is not true. There are some simple requirements of a good letter which are entirely subservient to the individuality of the writer. Remember, first, that the letter should carry some of the personality of the writer. Know what you want to say before you begin, and say it in your letter in such a way that the reader can not fail to see its logic. Be brief, but not too abrupt. Don't eliminate everything that goes to make smooth reading, but don't try to tell too much.

Let your letter be grammatically correct, but don't be afraid to use expressions of every-day use. Keep clear of stereotyped forms. Regulate "yours of even date," "would say," etc.; discard them, and also omit "herewith," "please find enclosed," "the same" and "thanking you in advance."

Routine Letters

Purely routine letters have been greatly simplified in some offices by preparing in advance a series of form paragraphs, which are kept on file. With a series of these form paragraphs in front of him the writer can frequently dictate an entire letter by merely stating to the stenographer that she is to use form paragraphs No. 1, No. 4, etc., as the case may require. The great saving of time in this way is at once apparent.

Disposal of Outgoing Mail

All outgoing mail is in the hands of the outgoing mail clerk, or a staff of clerks under one head. Their duties are to see that the outoing mail is gathered and brought to the mail room, that it contains all the specified enclosures, and is properly stamped and mailed. Where large quantities of mail are to be sent out both time and clerk hire are economized by addressing and stamping machines.

The various stenographers should address their own envelopes and make their own enclosures; or some one else in the department must be made responsible for this work, in order that enclosures for letters shall be enclosed in their proper envelopes. Where an enclosure is to be inserted it is well to put the word "enclosure" at the bottom of the letter.

To get the mail off as promptly as possible a boy should be sent around to the different departments every hour to collect all that is ready to go out. The plant and branch mail may be allowed to accumulate until the time for sending it, a schedule for which may be obtained at the post office. Most of the mail of a large business house will come to the mail room at the close of the day. This can not always be avoided, but so far as possible mail should be sent to the mail room at more frequent intervals.

U. S. READJUST INDUSTRIES FRO WAR WORK

For the purpose of developing new industrial resources to meet the war demands of the Government, and quickly to disclose additional means of increasing production, the U. S. War Industries Board has just established a Resources and Conversion Section. Mr. Charles A. Otis, of Cleveland, former president of the Cleveland Chamber of Commerce and a member of the Board of Directors of the Chamber of Commerce of the United States, has been appointed Chief of this Section.

To carry out the plans of the War Industries Board, it has been decided to divide the country into twenty regional groups and to organize each region through the commercial organizations within the region.

In each of these regions all types of industry represented in the membership of the business organizations and in addition all industries which may not be a part of such membership will be invited to co-operate.

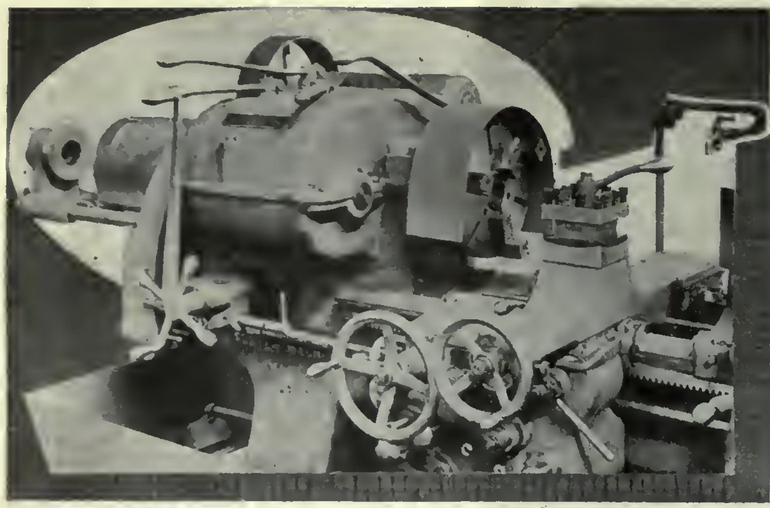
The purpose of this regional system is immediately to make a careful survey of every section of the country to determine what industries not now doing war work may be utilized for such work, and also to ascertain what industries already engaged on work for the Government are able to take on additional contracts or increase their production of munitions and war supplies.

SURFACE HARDENING BRONZE AND COPPER

In occasional instances it is desirable to harden the surface of copper and bronze, such things as dies being preferably so dealt with to enable them to withstand wear. This hardening is best done by alloying tin into the surface of the metal after the articles are finished, the process being as follows:—Metal which is machined all over—and not mere castings having the "skin" left on—is taken and all grease and dirt removed by well scouring with caustic potash or soda, rinsing in clean water and drying in non-resinous sawdust. The articles are then heated to a red heat and thinly coated with pure tin, and the heat continued for some minutes, when all excess of tin is wiped off with a piece of tow and the heat maintained until the tin left is absorbed, after which the articles are allowed to cool in the air. Or the articles can be thoroughly cleaned and have the surface thinly coated with tin in the usual way, using zinc chloride as a flux. The work must then be thoroughly washed in hot water to removed any excess of chloride of zinc, dried quickly, and then heated to redness in a muffle in which a reducing atmosphere is maintained, the process being complete as soon as the tin is absorbed. As the metals are somewhat tender at red heat, they should be kept on an iron plate or fire-clay tile during the period of heating. It is also possible to secure this kind of surface alloying with a blow-pipe flame, because absorption takes place at a red heat, as most persons using a copper soldering bit find out to their cost on occasion, and a "burnt" tinned soldering bit wants some hard work to file it up clean and fit for use for its proper purpose. The same principle is involved in "pyro-plating" on steel, in this case silver and gold leaf being used, and partly alloyed with the steel by heat in a close muffle.

THE SUCCESSFUL men are they who have worked while their neighbors' minds were vacant or occupied with passing trivialities, who have been acting while others have been wrestling with indecision. They are the men who have tried to read all that has been written about their craft; who have learned from the masters and fellow-craftsmen of experience, and profited thereby; who have gone about with their eyes open, noting the good points of other men's work, and considered how they might do it better. Thus they have carried themselves above mediocrity, and in striving to do things the best they could, have educated themselves in the truest manner.—Santa Fe Magazine.

TO BRONZE cast iron thoroughly cleanse the metal and rub it smooth. Apply evenly a coat of sweet or olive oil and heat the iron, being careful that the temperature does not rise high enough to burn the oil. Just as the oil is about to decompose, the cast iron will absorb oxygen, and this forms upon the surface a brown oxide skin which holds securely, and is so hard that it will admit of a high polish.



Combination Turret Lathe for Bar and Chucking Work

By Oskar Kylin

CURRENT events with their ever-increasing demands on the machine shop resources of theh world, both in equipment and labor, have resulted in widespread use of machine tools which enable semi-skilled labor to rapidly produce work of high accuracy.

Turret lathes in particular occupy a prominent place in the category of labor-saving tools influenced thuswise, and a recent example of this class of machine is described herewith. It is now being built by the Foster Machine Co., Elkhart, Ind., and is designated No. 2-B universal turret lathe, possessing combined features for both bar and chucking work.

This turret lathe is designed to handle bar work up to 3¼ in. in diameter and 30 in. in length, and chucking work up to 13 in. in diameter. It is possible, however, due to the larger swing over the horns of the carriage to handle lighter chucking work up to 20 in. in diameter. As shall be noted more in detail below, the designer claims for this machine the distinction of being the most universal machine of its class on the market today. This claim is based on several peculiar features of construction, the exceeding wide and well-balanced speed and feed ranges and the numerous standard, semi-standard and special tools and attachments with which the machine can be equipped. These features have made the machine capable of handling economically work of widely different nature and quantity covering a range of work from small lots of one-half dozen or less pieces up to work in large quantities where the machine is running continuously for months on one and the same job.

Head and Bed

Fig. 2 shows an interior view of the head with the head cover removed and the gears exposed. The twelve feed changes ranging from 12 to 325 r.p.m. are obtainable by means of sliding gears. The levers for operating these sliding gear clusters are mounted conveniently on the top of the head cover as shown in Fig. 1. The start, stop and reverse friction clutch is mounted on the back gear shaft and operated by the lever shown directly over the front spindle box.

The machine is driven by a 4 in. wide belt on a 15 in. diameter pulley, the speed of which pulley for high-speed cutting tools is 500 r.p.m. For stellite cutters when a higher cutting speed is required a pulley speed of up to 750 r.p.m. is recommended.

The belt running at a speed of 1,960 feet per minute is capable of delivering to the machine up to 8½ h.p., which corresponds to a torque at the spindle nose of 43,000 inch pounds, at a spindle speed of 12 r.p.m. The reason for this seemingly excessive power of the head is that this machine is frequently called upon to take up to 4 or 5 cuts simultaneously at a comparatively coarse feed which the machine is easily capable of doing. The friction clutch is capable of pulling a load equal to about twice the power delivered by the belt. The gears throughout the head are of the Fellows stub tooth standard, advantages of which are added strength and smoother, quieter action. All the sliding gear clusters and the gears engaging same are carbonized and heat treated.

The gears run in an oil bath and the bearings throughout the head are automatically lubricated by means of the splash from the gears.

The bed is very liberally dimensioned and heavily ribbed internally which makes same capable or resisting exceedingly heavy cutting strains without the slightest tremor or deflection.

Square Turret, Cross Slide and Carriage

The cross slide carriage which bridges and travels on the two very liberally dimensioned ways of the bed is shown clearly in title cut. The rear end of the cross slide is built in the shape of a table on which standard or special tool holders, such as required to carry wide forming tools or multiple necking tools can be mounted. The square turret mounted on the cross slide is indexed and bound by means of the lever handle mounted on the top of same. The lock-bolt which is of the cylindrical vertically-mounted type is located directly underneath the working position of the cutting tool.

Fig. 4 shows a view of the rear half of the carriage apron with gears and drop-off lever in place. The sliding gear clusters and the gears engaging same are made of chrome nickel steel. The gear tooth form is that of the Fellows' stub tooth standard. The lower gears in the apron run in an oil bath and all

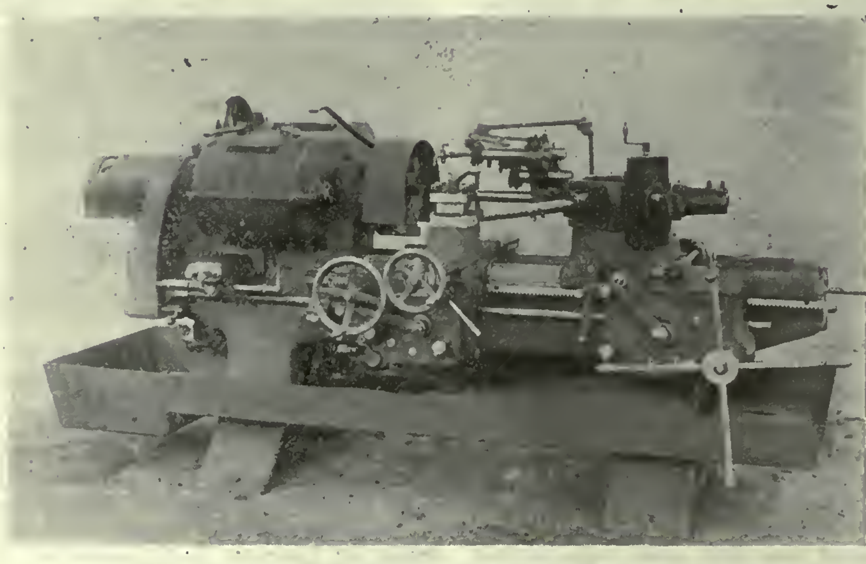


FIG. 1—UNIVERSAL TURRET LATHE WITH CHUCKING EQUIPMENT

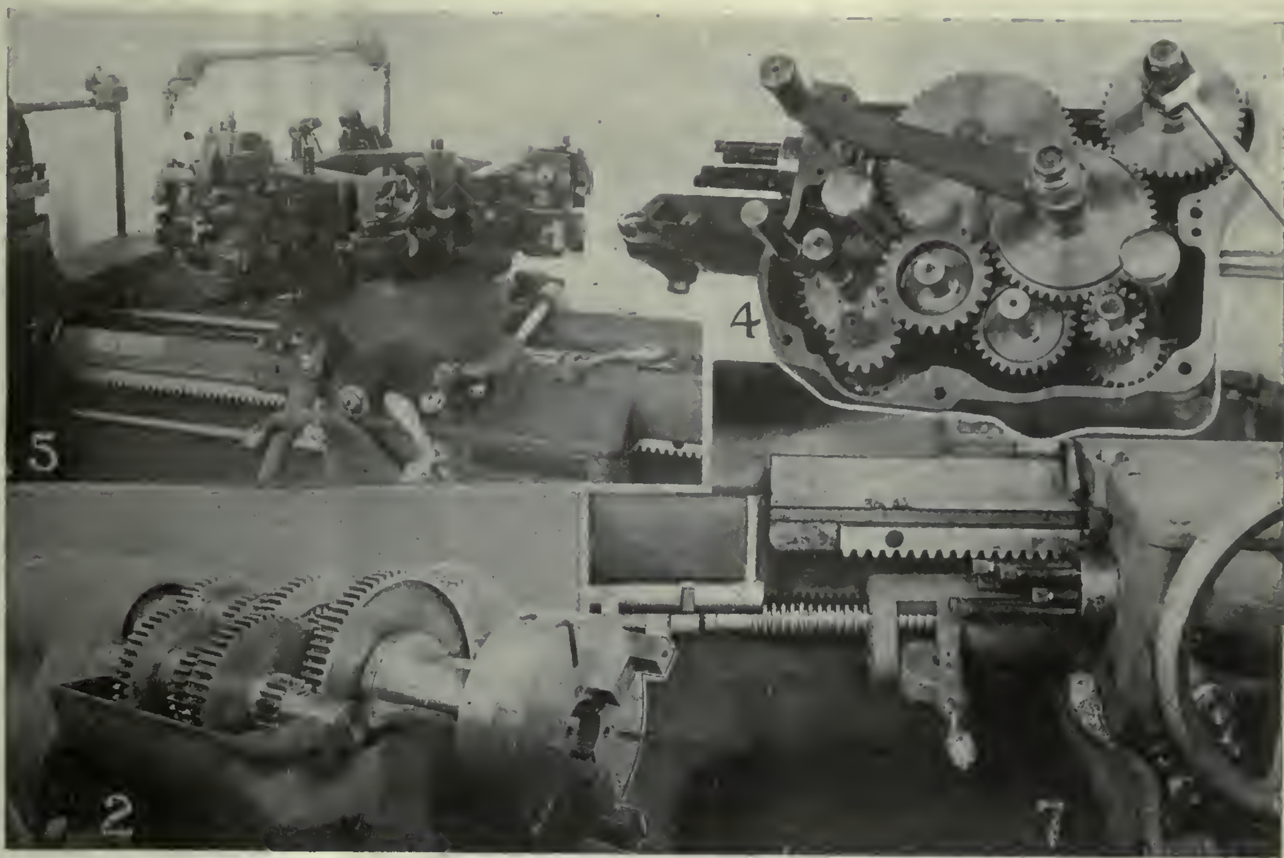

FIG. 2—VIEW OF HEAD WITH COVER REMOVED, SHOWING GEARS; FIG. 4—REAR HALF OF CARRIAGE APRON WITH GEARS AND SHAFT IN PACLE; FIF. 5—HEXAGON HEAD AND SADDLE WITH BAR TOOLS IN PLACE; FIG. 7—VIEW SHOWING SCREW-CUTTING ATTACHMENT AND CARRIAGE STOP

the lower bearings in same are automatically lubricated.

For the longitudinal gauging and duplicating of the work the carriage apron is equipped with six independent adjustable stop screws mounted in an indexable stop spool and abutting in turn a sliding stop rod mounted in a bracket secured to the bed. This butting of the stop screw against the stop rod causes the drop-off lever to drop and thus disengage the feed friction. The advantage of a drop-out feed friction above that of a drop-out worm is obvious, being that of instantaneous engagement. For duplicating and gauging diameters of the work, a large diameter dial is mounted on the cross-feed screw, which dial has in turn on same, adjustable observation stops. The cross-feed is disengaged by means of the short lever shown pointing to the right on the carriage apron.

The twelve feed changes range for the longitudinal feed from .0055 in. to .150 in. per spindle revolution and for the cross feed from .0029 in. to .080 per spindle revolution. Six of these feed changes and the reverse for same are obtainable by means of the sliding gears in the apron, which changes are multiplied by two changes obtainable in the gear box at the head end of the bed and which changes give two speeds to the feed rod.

Hexagon Turret and Saddle

The main turret which is of the hollow hexagon type and very liberally proportioned, is shown in Fig. 5 with bar tools mounted on same. The turret saddle which has an exceptionally long bearing on the bed has mounted on same, an apron very similar in design to that illustrated and described above for the carriage. The drop-off feed friction which is automatically disengaged in a manner similar to that operating the feed friction for the carriage apron is here controlled by stops adjustably mounted on a long stop roll located between the ways of the bed. This stop roll is long enough to take care of work up to the maximum length capacity of the machine.

The saddle is equipped with quick traverse which is operated by means of a lever mounted on the front side of the saddle and shown in Fig. 5. The quick traverse mechanism itself is illustrated clearly in Fig. 6, being mounted on the rear side of the saddle. It consists of a right and left hand screw with nuts which are intermittently locked by means of a double friction controlled by the lever on the front side of the saddle as mentioned above. A rod adjustably

FIG. 6—REAR VIEW OF 2-B UNIVERSAL TURRET LATHE WITH AUTOMATIC CHUCK AND MOTOR DRIVE

mounted in a bracket secured to the rear end of the bed automatically disengages the quick traverse and thus limits the rearward movement of the saddle. The quick traverse screw which is fully protected from chips and dirt by means of the telescoping tube is driven by a bolt from the main driving pulley.

Automatic Chuck and Bar Feed

The automatic chuck which is of the standard collect type construction is shown in Fig. 6. The main point of interest in connection with same is the short overhang of the end of the automatic chuck beyond the front spindle bearing. A new lever action for operating the automatic chuck wedge has been introduced and has proven to facilitate greatly the ease of operating the automatic chuck and increased the gripping power of same. The bar feed head travels on two parallel bars, the outer ends of which are supported in a rigid stand.

Attachments

As has already been mentioned, the machine can be equipped with screw-cutting and taper attachments. The screw-cutting attachment, which is of the leader and follower type, can be seen clearly in Fig. 7. The leader, which is mounted on the main feed rod, is capable of cutting two pitches of threads in the multiples of one and four of that of the pitch of the leader. The follower is mounted in a lever in a projection of the carriage apron.

The taper attachment which is of exceedingly rigid construction is mounted on the rear end of the carriage and operates directly on the cross-feed nut. Same is very simple in design and can be seen clearly in Fig. 6.

Standard Tool Equipments

Very extensive and complete tool equipments for both bar and chucking work are designed for this machine. Fig. 1 shows the machine with a few of the chucking tools mounted on the hexagon turret but this illustration can only give a faint idea of the real merits of same and the extent to which the designer has studied and solved the problem of standard tools. Fig. 5 shows a view of the most commonly used bar tools.

General

The machine can be driven either from a countershaft or by means of an individual motor which is usually mounted on the front leg in a manner shown clearly in Fig. 5.

The system of supplying coolant in abundant quantity to the cutting tools has been thoroughly studied and is also shown clearly in Fig. 6.

The machine weighs, complete with automatic chuck and bar feed but without standard tools, 5,200 pounds.

CREATING THE REAL-MAN TYPE

By James E. Cooley

WE, who are part of the great planetary system, and who occupy a small patch on this hemisphere, need to undergo a reconstruction; a change tremendously broadening, before we can boast of greatness and civilization outvying that of historic time. We need to bury our prejudices, our weaknesses to overcome helplessness, and to undergo a rebuilding, in order to become a stronger race of men and women

We need to make a few radical moves and do things almost the other way round from what we are in the habit of doing them. Our high order of intelligence is far below what we would have posterity think it is. It has little of the summit-height, the cloud-altitude upreach; and we are not as yet a race of "high-brows."

We are sadly lacking in dash and spirit. No evolutionary period confronts us. We are still too languorously hide-bound to beds of ease and stolid indifference. Our growth is too slow. We still are lacking in the power of constructive thinking and acting, too deeply absorbed in things that are of little or no permanent value to us. Being such, we are sadly neglecting that, which might lead to our higher welfare, to a higher progressive state of existence.

There are a thousand and one details in life that demand our present attention; and one is as fully important as the other. It becomes us to know what each of these are. It becomes us to know how each of these needs handling. And it becomes us to tackle them vigorously and with our greatest energy.

The proper and necessary step to take to start us moving towards a higher progressive plane is first, to get the right perspective, and then to plunge ahead. If debris and refuse adorn your premises, if your home or factory and their contents are in upheaval and disorder, clean and straighten these up. Have a place for everything, and everything in it's proper place. Straighten and clean up your person. Keep your body clean, your nails evenly pared and manicured. Have your clothes spick and span. Keep the soles of your shoes well shod, your worn-over heels trim and smooth. Keep in condition always. Do not neglect the least little thing, nor do these things at spasmodic intervals. Be regular, erect, and strictly attentive. "Get the habit" and get it strongly.

If you proceed in this course, others will follow you in their turn. You will have begun to do your work better. You will feel better. Your spirit will become more animated, to move with greater forwardness. In this line of "culture" the ground plan of a progressive state will have been laid. A thousand and one improvements are bound to spring up on this. Men like yourself will strive more fervently. The study of medicines, the arts, and invention, will take on a new encouragement. Diseases, such as cancer, the "great-white plague," will be overcome; or each new disease or epidemic will be checked as soon as it appears. Childhood will get its full growth. Infant mortality will be a thing of the past. And new scientific discoveries will be the order of the day.

But we must first understand that it behooves us to wake from our indifference and indolence and take energetic measures and direct our efforts only in those things most useful and progressive. Putting down what hinders; purifying what is unclean, and making habitable and healthy all places wherein mankind works and dwells.

It is only as we work ourselves up and have that filled-with-vivacity promptness; that filled-with-battle-spirit-and-plunge go; that clear-as-a-crystal positiveness that we shall make any noticeable headway in whatever we try to attempt. But having these, developing them to the fullest, we are on safe ground to go ahead in trying to do something useful and big.

Again we may repeat, it is only when we get the right perspective, sense the need or needlessness of things, and face them squarely, and work indefatigably, that we are going to overcome the ills, the menaces, and inconveniences that man is heir to. It is only as we create the real man type—the man with a constructive mind—with the broad and higher outlook on things and affairs. Sweeping, where it needs brushing, digging up what should be removed.

The difference between this type and the present one is the difference between one who is confident and self-assertive, from one who is hesitant and vacillating; or the difference between a being having an unbreakable vertebrae, a stiff back-bone, from one who is hopelessly spineless. The man who uses his brain, who is sure-footed and forward, has the upper-hand on himself and his work and lacks nothing. Behind him, his confidence is his own fortress; ahead of him, his self-assertiveness is his field of great human endeavor.

Over the vast assemblage with with this earth is peopled, one must look long to find the very few if any of this type. It becomes us therefore, to create them. First, beginning with our own personal selves, and then enthusing others to become supreme and foremost, to do a man's part, and act a man's part. Where scenes and environments require changing, where trackless fields and deserts are still untrod, where seas and worlds remain undiscovered, there is our work ahead, there is our right task, our rightful inheritance.

If you have become this real-man type, that looks eagerly forward with a hopeful view, a broader outlook on each coming morrow, if you have become fully aroused out of a stone-hard stupor, if you have developed your strength, your unobscurable powers of scrutiny to see the grand possibilities of destroying the evils and errors of life, creating anew what is antiquated, if you have become a sound vigilant body, clothed with mightiness and greatness, all then that you do, all that you attempt to do, you will not only add to your glorification but you will stand out as an incomparable real, live, active human being, a credit to your race and time.—

Corrosion of Iron and Steel, and Its Prevention--VI.

By Abe Winters

Perhaps the most pathetic feature of man's existence on this planet is illustrated by the contrast between the immense metallurgical and manufacturing industries based on iron ore, and the loss of finished metal due to corrosion. Sometimes obscure, sometimes prominently noticeable, the ravages of rust are the most relentless of all handicaps which man lives under, undoing with hitherto unpreventable certainty that which he has done.

FARADAY'S law of the corrosion of metal in weak acidulated solutions and electrical energy applied to the anode is 1.0448 grains of iron per square foot per ampere hour. The film formed over the surface of iron or steel by the process under consideration is an insulating film, the insulating properties of the film render the processed metal impervious to galvanic currents or electrolytic corrosion as long as the film is intact at every joint. Hydrated rust carries over 20 per cent. of moisture, and so long as it can attack a fresh surface of iron and cast off the thin film of oxide as it forms it will release enough oxygen to begin another cycle of action. A pin scratch on a phosphorized steel surface will be sufficient to allow corrosion to begin and eventually destroy the entire article. Tests made under our personal supervision verify this statement.

Rust which forms on iron or steel is hygroscopic and carries 24 per cent. of moisture as it forms. This moisture never dries out under any atmospheric heat conditions, but is ever ready for a chemical decomposition; the hydrated red rust being nearly twice the volume of the iron from which it is formed, adds its efforts to the free hydrogen to push through the phosphate film and eventually create havoc over the entire surface. This mechanical action is far more energetic than mere casual observation would lead one to imagine. A very important requisite of rust-proofing coatings is a galvanic property to protect the underlying iron which may become exposed by scratches or pinholes. This property is totally absent in coatings produced in phosphorous-manganese solutions by simple immersion. The coating is non-metallic and the temperature at which the solution (212° Fahr) does not influence the structure of the metal surface or expand the pores of steel sufficiently to permit a penetration exceeding .001 inch.

Properties of an Ideal Rust Preventative

An ideal protective coating should be completely resistant, not only to chemical corrosive agencies but should be hard and tough to resist mechanical wear or abrasion. It should be capable of protecting the underlying metal by galvanic action. All rust-proofing films formed in acidulated solutions containing manganese dioxide, calcium or ferric oxides, do not possess properties conducive to automatic galvanic protection, furthermore these solutions are more expensive to operate commercially than the average manufacturer would expect after only a partial investigation of the process. It is not the intention of the writer to absolutely condemn phosphorous-manganese rust-proofing for iron and steel, the process has many very excellent features and is by no means totally ineffective or unscientific. The phosphate coating is more resistive to atmospheric influences than is generally admitted. If the coating is further protected by oil, wax or paint the results are often very satisfactory. Responsible authorities agree that for many purposes, particularly on small wares, the phosphate process is efficient and may be used commercially at reasonable cost. The excessive costs are usually the result of high chemical expense and unnecessary waste.

Group No. 4

In this group we have several metals which are electro-positive to iron, which would give us the desired result; some of these are antimony, arsenic, potassium, sodium or zinc, but about the only practical or commercial metal in the class is zinc. Zinc is a peculiar metal of pronounced characteristics. It is relatively low in malleability, ductility, tenacity and infusibility when compared with other metals. Zinc has a melting point of 419 degrees C., and under atmospheric pressure a boiling point of 918 degrees C. On this basis of silver at 100, zinc has an electrical conductivity of 29 and a heat conductivity of 36. It is practically non-corrosive in the atmosphere, a thin protective coating of carbonate of zinc forming upon it. Zinc is one of the highest electro positive metals, it having a potential of 0.493 volts.

Hot galvanizing, or the application of molten zinc to a metal is a commonly known process. The quality of the coating depends not only upon the size and nature of the article but also to a large extent upon the skill of the operator, who must use care and give constant attention to the work.

Cold galvanizing or electro-plating is the process of depositing a coating of zinc upon the metal to be protected by means of an electric current and an electrolyte. For many purposes cold galvanizing has proven particularly efficient, but, has never been regarded as a practical rust-proofing process for use on wares which are subjected to unusual corrosive influences or ordinary abrasive action resulting from natural causes. There are several very simple formulas for acid zinc plating solutions, these being more generally employed. Cyanide zinc plating solutions are to be preferred for some purposes, but the maintenance cost of cyanide solutions is an important consideration in commercial practice.

Sherardizing

The Sherardizing process of coating iron and steel with a rust-proof film of zinc was discovered in an accidental manner by Mr. Cowper Cowles of London, England, but is not essentially a modern idea as a process practically the same was known in prehistoric times; it, however, was used for a different purpose. Copper tools, vessels, etc., were placed in the ground in certain localities and kept hot by fires built over the spot, on removal the copper was found to have acquired a light yellow color and become harder. This was really dry galvanizing although an alloying of the two metals was not recognized. In Greek history Aristotle records the "bleaching of copper" by the same method.

Sherardizing is to-day a patented process but is without doubt the most effective rust-proofing process known for general purposes. Naturally there are many cases where the requirements favor such processes as the application of vitrified enamel, phosphate films or hot galvanizing, but for the majority of modern commercial needs the treatment of iron and steel by the electro-Sherardizing process is the acme of perfection for the production of protective coatings. Samuel Trood has refined the process of Sherardizing as follows: A process of sublimation, occlusion and adhesion, when considered in connection with the theory of ions. The process of passing directly from the solid state to the gaseous state and from the gaseous state direct to the solid state, in both cases stepping over the liquid state, is called sublimation.

Zinc as a solid may change into vapor without passing into the liquid state. For an exact definition of the physical condition of a body a knowledge of the values of all its variable properties is required. The three most important of these are temperature, pressure and volume occupied by unit mass of the substonce. It is a well known fact that the common metals are extremely porous. This is visible under a high power magnifying glass, as well as readily demonstrated by certain physical experiments. The condition of the metal may be graphically described as resembling a sponge soaked with water.

Occlusion

When a porous solid is easily permeated by a gas and condensation on the surface of the pores of the solid takes place it is called occlusion. An example of this may be seen in the absorption of 90 volumes of ammonia in one volume of charcoal. Nearly all metals absorb gases and, being heated, will allow them to pass through readily. An example of this is the fact that hydrogen will pass through heated iron. When a gas is in contact with a solid there are molecular forces drawing the particles together and this produces a surface condensation of gas on the solid. An example of this is the frosting of window panes in irregular figures. There also appears to be an electrical condition accompanying the evolution of gases from a metal inasmuch as the evolved gases usually contain a number of free ions. Naturally the exposed surface of the metal is the only portion which actively takes part in evolving gases so that the larger the area of surface exposed the greater the evolution of gas, other conditions being equal.

To be continued

BIG U. S. FIRM'S CAMPAIGN FOR LIBERTY LOAN

Final reports of the Liberty Loan Campaign among employees of the Westinghouse Electric & Mfg. Company and its subsidiaries show that the total subscription was $2,601,000. Of this, $2,217,000 was taken by employees of the parent company. Three subsidiaries showed 100 per cent. of employees subscribing—the R. D. Nuttall Company, the Krantz Mfg. Company and the Pittsburgh Meter Company. In addition to this, the Krantz employees subscribed the largest per cent. of the total payroll—10.4 per cent. and the largest amount per subscriber $87.27. Electric Company employees to the number of 32,048 subscribed $69.18 per capita, 5.2 per cent. of the payroll. All figures show a gratifying increase over those of the second loan, showing that Westinghouse men and women are solidly backing their four thousand fellow workers now with the colors.

THE KAISER'S EFFIGY

As might be expected in a company employing over 30,000 people, comparable to a good-sized city, the third Liberty Loan Campaign possessed some unusual features.

MEETING HELD DURING THE PROGRESS OF THE LIBERTY LOAN CAMPAIGN.

In order to cover the entire works thoroughly from office boy to executive, team captains were appointed who in turn selected their lieutenants and teams. The members of these teams sold every employee a bond, or got a very satisfactory reason for the refusal.

In one instance, when a widow woman, the sole support of several children, felt that she simply could not afford the purchase of a bond, the women employees of her section chipped in and secured one for her, every woman contributing.

Speaking of the part the girls played in the campaign, it is interesting to note that the telephone and sales records departments, composed practically altogether of girls, were among the 100 per cent. departments, that is, every employee a bond owner.

Considerable enthusiam was aroused among the workers by the appearance during the campaign, of Sousa's Great Lakes' Marine Band, that gave a concert in one of the large aisles of the works, and was cheered to the echo by thousands of Westinghouse employees who gathered to listen.

Considerable amusement was afforded on this occasion by the appearance of a grotesque effigy of the Kaiser, which was hung in full view of the large crowd. This likeness was built by some of the employees out of nearby materials and clothed in old discarded rainment.

SO MANY new problems face naval designers and marine engineers to-day that it is well to note with exactness the advances which have been made in mechanical efficiency, and the notorious shortcomings for which modern engineering is seeking a remedy. Even the scheme of standardized ships, does not claim any advantage beyond that of economy in building a number of vessels of identical type, so that the engineer cannot expect from the reproduction of familiar experience implied in such a scheme any help in overcoming the problems of engine equipment, boiler designs, propeller eccentricities, skin resistance, fuel economy and so on.

The engine room of any ship generates enough engineering questions to provide societies with ample material for discussion. From the voluminous discussions which have taken place, it is possible to ascertain the status of the Diesel engines, none of which, by the way, resemble the original productions of Diesel, the nominal inventor of them. The marine Diesel is bound to undergo changes before it becomes an all-round proposition, and it is to this that many engineers are devoting themselves at the present moment. The possibilities of application to war vessels can be stated briefly. Modern destroyers and light cruisers, as a rule, are propelled by means of high-speed turbines, supplied with steam by water-tube boilers of large power per unit and generally oil-fired. Speed being the great essential for such vessels, lightness and compactness of machinery are vital. Such steam-propelling machinery with auxiliaries will weigh from 27 lb. to 35 lb. per shaft H.P. The lightest Diesel engines weigh (without the auxiliaries) about 56 lb. per B.H.P. and consume, say, about ½ lb. of fuel per B.H.P., whereas steam turbine installations with auxiliaries, weigh about half as much per S.H.P., the consumption of oil fuel being rather under 1 lb. per B.H.P.

Methods, Machining Devices, Systems and Suggestions From Shop And Drafting Room

THE CAUSE OF BROKEN CRANKSHAFTS

By Maurice M. Clement

THE breaking of the crankshaft in the engine is a more common occurrence than is generally supposed It is often a break that only can be repaired by supplying a new shaft; there is at times a great deal of contention on the part of the owner of the engine in trying to establish a flaw in the material, whether one really exists or not. In many of these cases the claims of defect are well founded when superficial appearances only are considered; I am not far wrong in saying that in 70 per cent., of broken cranks the break shows that at least a portion of the shaft's diameter has been parted for some time, in other words, the separated points indicate an old break for from one-half to two-thirds the diameter of the shaft or less.

Only the remainder of the diameter shows a fresh break. The parts showing an old break often have the appearance of never having been united; with this condition of affairs an owner of a shaft is apparently justified in laying claim to a defect, and his claim should receive every consideration that justice and fairness demands, but the real condition that leads up to and causes the break should not be lost sight of; in the large majority of cases we can feel sure broken shafts are the result of loose journal boxes. It is not an uncommon thing to see an engine in operation that shows the crank shaft jumping in one or both journal boxes at each impulse the piston receives.

It is a matter that may have been noticed by the operator and lightly regarded; in his opinion it is only a trivial matter. Oftentimes this loose condition of the boxes entirely escapes the notice of the operator. But it is not a difficult matter to see how loose boxes may result in broken shafts; in the first place, we must consider the heavy flywheels that are carried on the gas engine shaft, these heavy wheels are quite necessary on a moderate speed engine of the single cylinder type to get the best results in power development, steady speed and fuel consumption. If properly carried by the shaft they are really an aid to its long life rather than a detriment.

Broken crank shafts would in my opinion be a very uncommon thing, if the journal boxes and wrist boxes were more carefully looked after and kept properly adjusted. The intent of a box or a number of boxes carrying a revolving shaft is to keep the shaft in perfect line at all times. A box cannot accomplish its purpose on a gas engine if it is not carefully and snugly adjusted all of the time. The sudden force applied to the piston of the gas engine and through it and the connecting rod to the crank shaft tends to lift the shaft out of its journal box bed at each impulse, even with the weight of the heavy flywheels crowding it constantly downward into its bed. If the boxes are snugly fitted, this lifting motion cannot occur, but, on the other hand, if the box caps are loose, each impulse raises the shaft and wheels, and as soon as the force of the impulse subsides the weight of the wheels and shaft bring it down into its bed again with a thump.

Now if only one journal box is loose and the other one is properly adjusted, the lose end of the shaft only will jump, throwing the shaft out of line at each impulse; this condition may be regarded as even worse than where both boxes are loose, now add to the loose box or boxes the weight of the belt and drive pulley on the shaft and the cause for a great many breaks can be easily explained.

As before intimated, a shaft seldom breaks all at once. The condition that really causes the break has been in existence and started the trouble a long time before the final complete rupture comes; there is an unintentional and undue strain on the shaft every time it jumps in the boxes, this continual heavy strain at regular intervals soon causes what is known as crystallized condition of the metal in that part of the shaft where the greater strain occurs.

The crystallizing of the metal destroys the tensile strength of it, and it becomes fragile, usually this crystallized condition begins at a point on the outer circumference of the shaft and travels toward the center. It does not necessarily, and in fact not generally, affect the entire circumference. A third or half of the circumference only is the rule. At this fragile point a crack is started by reason of the continued jumping of the shaft in its bearings; as the crystallized condition grows the crack grows deeper until finally the good metal remaining is no longer able to withstand the strain and breaks in two; when the broken ends are now examined, the fresh break shows only so far as the good or adhesive metal held on. The original crack may have been started weeks or months before, and the constant motion caused the broken parts to rub together until they often appear as if they have never been united.

Many times the owner of the engine uses the expression, "that was never welded properly," or "the shaft was only partly welded." The common opinion or supposition among many engine owners that crank shafts are welded together is illfounded. Cranks are generally made by either the drop forging or steel casting process. No welding process whatever enters into their formation. Another process of making crank shafts is cutting them out of solid steel billets; the large majority of broken shafts, I believe, are a direct result of a jump in one or both journal boxes.

A peculiar case came under my notice recently. Three shafts in one 25 H.P. engine broke within a period of one year, and all of them broke at practically the same point; the conclusion was that some unusual condition existed bout this engine which was to blame. Upon investigation, it was found that a special length was required in this shaft for the purpose of accomodating an extra heavy and wide belt; an extension shaft was coupled on to the end of the regular shaft and an outer bearing was supplied for this extension. The outer bearing was found to be out of line with the boxes on the engine base, and in order to run at all with cool boxes the operator concluded he must run with very loose box caps; he did so, with the result already stated.

I never look at a jumping shaft but I feel an immediate desire to get out of the engine room as far away as possible from the engine until it is shut down and the boxes adjusted. And yet how many an operator will tell you that he has operated his engine with loose boxes for a long time, others are as particular to have the journal boxes of their engines properly adjusted as they are to have a good igniting spark.

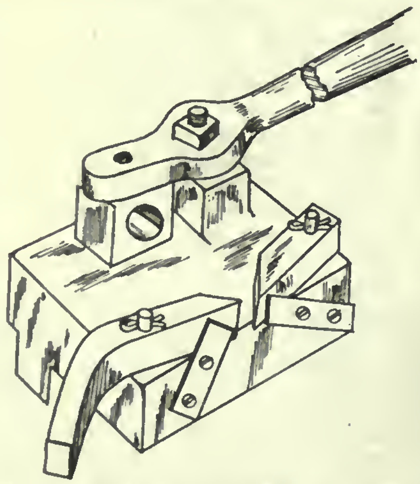
Another fruitful source of crank shaft breaking in the gas engine is premature ignition of the charges, which results in pounding in the cylinders. Ignition in these cases comes before the piston has completed its compression stroke and the expansive force resulting from the explosion tends to reverse the piston instantly and drive it back; but the momentum of the flywheel is sufficient to overcome this reversing force. The result of this clash of forces is an extra heavy strain on the crank shaft and possibly to other parts of the engine. The crank shaft is an extraordinary vital part of the engine, as well as a costly one, and it is therefore important, that every owner and operator see to it that anything tending to affect adversely smooth running should be promptly remedied.

Especially is it necessary to give all reasonable amount of time and attention to seeing that the wrist and journal boxes are in snug adjustment and properly lubricated.

A CARTRIDGE JOB

By D. A. H.

SOME thirty thousand cartridges for the Ross .303 rifle had been assembled with their jackets when it was discovered that the jackets had somehow been underfilled and the charge of lead in them was too light. It was decided to "draw" the jackets and scrap them, but to save the cartridge cases and the work was sent out to a job shop as being the proper place, so as not to interfere with the regular work of the plant. Anyone who has tried to pull the case off the jacket of a Ross bullet will tell you that it is more difficult than almost any other make, the fit being unusually tight and the jacket being set in farther than in most cases. A simple rig was made that extracted the jackets without any trouble



JIG FOR DRAWING JACKETS OF ROSS RIFLE CARTRIDGES.

though they were considerably damaged in the process.

A casting was made up to be held in a vise; to facilitate this, a lug was cast on the under side for the jaws to grip upon, which made a solid rig to work with as the plate itself rested on top of the vise. Two jaws of tool steel were pivoted near one edge of the plate with the working ends projecting over the edge where they were acted upon by flat springs. The lever shown was fitted with a swivel piece having a hole, the size of the cartridge case just under the head, placed in line with the space between the two jaws. This constituted the device which it will be seen worked on the toggle principle.

In use, the cartridge was slipped through the hole in the swivel block and the thumb kept against the head while it was pushed between the jaws against the pressure of the springs, the latter being comparatively light. A pull on the lever in the opposite direction, coupled with the spring pressure, caused the jaws to bite in the jackets and resist further movement; with the jackets held fast, the cases had to draw off as the lever was pulled further, sufficient length being provided to make the work easy. One of the jaws was extended to form a knockout, a touch on it freeing the jacket which rolled into a box beside the vise.

TURNING ALUMINUM DISCS

By D. A. N.

On the well known Metz automobile, the transmission is of the friction type with the driven member an aluminum disk about 18 inches in diameter and 5/16 inch thick, mounted on a deeply ribbed spider. In the course of time and through abuse, this disk gets scored up so badly that shifting is difficult and the driver wears out very rapidly. The logical way to reface the disk is to leave it on the spider where it is well supported and a good means of driving is available, but no, the Metz owner usually does his own work and he sees what is evident to the trained mechanic, that it is easier to remove the dozen screws that attach the disk than to remove bearings and brackets and take out the whole driven unit. Thus there comes to the machine shop an aluminum disk 18 inches in diameter by ¼ inch thick, or less, to be turned off true and straight.

One way to do the job well is to drill and tap the face plate of the lathe for flat-headed screws and to screw the disk to the faceplate just as it is fastened to the spider in the car. This is the ideal way, but some men will not want to drill up a face plate (a practice which is hard to control, once started) and others may not have a face plate big enough.

The planer will do the job quite satisfactorily and will turn out a disk that is of more uniform thickness than will a lathe that does not, of itself, face straight. By clamping the disk flat on the table and cutting not more than two inches of width at a time a satisfactory progress is made and a good cut secured. Care must be exercised to keep the piece well clamped at all times—it should not be entirely loosened up until the job is done. After cutting a section, the clamps are shifted, but before shifting a clamp is put front and back on the newly planed part to keep it down and clamps are put at the edge of the section to be next cut. A little hustle on the part of the planer man will produce as good and quick a job as could be done on a lathe. If a polish is desired, sand paper over a wood block will answer.

The question will be asked, "Why not chuck the disk?" It is so thin that it buckles under the grip of the chuck jaws which means that the cut might be straight and true in the lathe but very uneven when assembled on the car. There is no backing provided by the chuck and it is hard to grip so a cut can be taken over all, especially if the jaws are a little worn.

THE DECAY OF METALS

By decay of metals is meant changes of an unfavorable character that take place when in use or in storage, especially those that proceed completely through the mass of the metal. The simplest of these is the disintegration due to molecular change of the kind known in chemistry as allotropic. This is especially observable in tin, which becomes unstable at 644 degrees F. and may gradually change from a tough white metal into a gray powder. This condition is first manifested as small spots at which mounds of gray powder soon appear. In a short time, each spot becomes a hole, which rapidly perforates the metal. A peculiarity of this trouble is that it rapidly spreads from one place to another, like an infectious disease; it is therefore known as the "tin plague." In cold countries like Russia, the tin roofs of the affected areas are quickly destroyed when the process of decay is started. It seems as though the powder must be carried by the wind, and that wherever it settles it starts the tin decaying. Tin is also likely to undergo a molecular change at the temperature of boiling water. This is shown by the columnar structure that is frequently found in pieces of broken condenser worms. Allotropic changes occur also in lead, especially lead sheets subjected to the application of solutions containing lead salts. This change does not appear to be connected with the impurities in ordinary lead, as it seems to occur as readily with common sheet lead and the purest assay foil.

Decay may also be due to the movement of gases dissolved in a metal. This is the cause of the brittleness of nickel wires used as resistances in electric furnaces. The heating of the wire sets free the dissolved gases invariably contained in nickel. As the cooling between two periods of use is too rapid for a complete reversal of the process, a part of the gas remains undissolved between the grains of metal. As this alternate heating and cooling continues, the grains separate and the wire crumbles.

RATE MAKING—The mere fact that in the case of the wholesale customer for electric energy the public service company would be exposed to the competition of a possible isolated plant, whereas in the case of the retail customer there is no possibility of his supplying himself, does not afford any legal justification for difference in charge. In other words, the possibility of competition is not to be taken into consideration in determining the reasonableness of the classification.—Louis D. Brandeis.

The Machining of Aero Engine Parts

FIG. 1—A GROUP OF ROTARY ENGINE DETAILS MACHINED ON TURRET LATHES

The machining of many of the parts of Aero engines necessitates considerable care and ingenuity for its accomplishment. The following article reproduced through the courtesy of Alfred Herbert, Ltd., illustrates some of the more difficulty operations.

THE rotary type of aeroplane engine must of necessity be accurately balanced, since the whole engine revolves at a very high speed. It is necessary, therefore, that the components be machined all over, which necessitates a larger proportion of lathe work in this type of engine than in the fixed type. Almost all the lathe work is suitable for handling on combination turret lathes or capstan lathes, and with correctly designed lay-outs of tools may be machined with female labor to the close limits required on such work. The fact that most of the work is slender and liable to distortion necessitates roughing out all over before starting the finishing operations, and this has the advantage that in consequence the tools can be spread evenly over the operations so as to avoid undue complication and confusion to the operator.

The crankcase at the left hand side is a formidable piece of lathe work, the form of the rough material being the cylindrical block of steel shown. The centre portion of this block is trepanned out, and the blank roughly machined to shape before being handled on the combination turret lathe. The holes for the cylinders are also rough bored.

Our No. 9 combination turret lathe is used for the finishing operations, which are split up into six chuckings. One of these operations is shown in Fig. 2, the work being held in an 18-in. Coventry chuck. The special boring head is worthy of note, and is shown in greater detail in Fig. 3. It carries four cutting tools, which are clamped in steel blocks bolted to the casting. Boring heads of this type assist greatly in increasing production, and should be employed if the quantities of work are sufficient to justify making them.

Fig. 4 shows another of the operations in which profiling slides are used for finishing the interior of the crankcase. As the internal spherical surface is interrupted by the cylinder holes, it is not possible to form it, and it is, therefore, traverse bored by a single point profiling slide actuated by a former carried in the square turret.

The piece of work shown in Fig. 5 on a No. 4 capstan lathe is the short end of the crankshaft; it is located in the special fixture by the pin which has been previously turned. The hole is taper, and is finished with reamers.

In Figs. 6 and 7 we show two operations on the medium nose piece which is bolted to the front end of the crankcase. This carries the propeller boss, the shank being tapered to suit.

There are four operations on the No. 9 combination turret lathe; at the first and third the work is held as in Fig. 6, whilst at the second and fourth the work is held as in Fig. 7. The first and second operations rough out the work, leaving about 1 m/m on all surfaces, whilst the third and fourth operations are sizing operations on the corresponding surfaces. At operations 1 and 3 both sides of the rim are finished, so that it can be clamped on to a face plate fixture in operations 2 and 4. The special double facing tool will be seen on the back of the cross slide (Fig. 6).

A very difficult piece of lathe work, shown in Fig. 8, is the thrust block with which the connecting rods engage. The stamping is of high tensile steel, and the three grooves are trepanned simultaneously. The trepanning head shown is for roughing, but in the finishing and sizing heads lateral adjustment is provided for the cutters, which are arranged to cut on one side of the grooves only. Similar trepanning heads are used for machining the thrust block liners, which are finally pressed into the thrust blocks.

Figs. 9 and 10 show two operations on a propeller boss. At the first operation the taper bore and the two sides of the flange are machined. The multiple cutter boring bar shown in position carries a series of round cutters, which step out the taper bore very closely to shape, leaving a comparatively small amount for the taper reamers to remove, which

in consequence stand up for long periods without grinding. At the second operation the work is clamped on to a face plate fixture mounted on to a Coventry chuck, whilst the outside of the boss is turned and the end counterbored.

SAVES MONEY BY ARC-WELDING

Arc-welding has been brought prominently before the public through the fact that it was used to restore the broken engine castings of the interned German ships. When breaking these castings the Germans thought they could not be repaired, and that it would require a year or more to replace them. However, even before the ships could be otherwise overhauled and made ready for transport service the broken castings had all been repaired and were good as new. This achievement has impressed the value of arc-welding upon the minds of many shop managers, and in many plants castings and other parts of apparatus which in the past would have been scrapped as hopelessly damaged, are now perfectly restored by the arc-welding process at small cost and great saving of time.

One large manufacturer, working on munitions, has installed a Westinghouse arc-welding equipment for the sole purpose of making tools for turning shells.

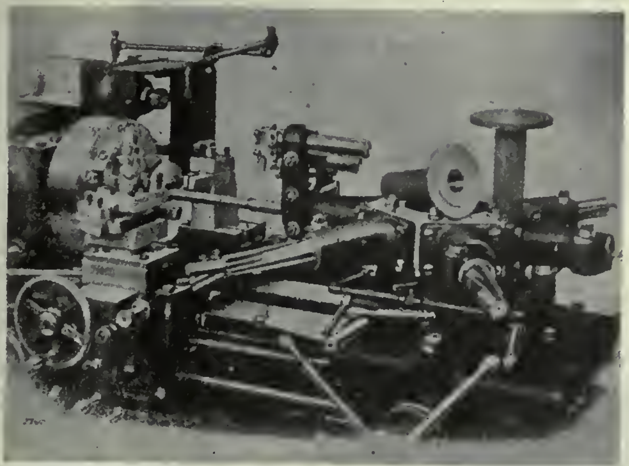

FIG. 10—SECOND OPERATION ON THE PROPELLOR BOSS

Ordinarily these tools ar[illegible] from high speed steel and cost about $12.00 each. This manufact[illegible] speed steel for the tip of the tool only, welding it to a shank of carbon or machine steel, and in this manner the tools are produced at a cost of $2.00 to $4.00.

For several weeks this plant has been turning out 240 welded tools per day, the men working in shifts of four, which is the capacity of this outfit.

The equipment consists of a 500-ampere arc-welding motor-generator with standard control panel, and three outlet panels for metal-electrode welding, and one special outlet panel for the use of either meal or graphite electrodes. This special panel is intended to take care of special filling or cutting processes which may be necessary from time to time, but it is ordinarily used in the same manner as the other panels, for making tools.

These four panels are distributed about the shops at the most advantageous points for doing the work, it not being necessary to have them near the motor-generator or main control panel.

For tool making, which involves the hardest grades of steel, a pre-heating oven is used, not because it is necessary for making a perfect weld, but because otherwise the hard steel is likely to crack from unequal cooling, and also because pre-heating makes it easier to finish the tool after the welding process has been completed. For ordinary arc-welding operations the pre-heating oven is never used.

INDUSTRIAL EDUCATION

By A. L. Haas.

It is a matter of common knowledge that a statutory measure of far-reaching importance is before the people of Great Britain in the form of a new education bill. In addition to co-ordinating virtually all existing educational resources the new Minister of Education, Mr. Fisher, has incorporated some basic compulsory proposals as to the age for school leaving. The two most radical proposals are compulsory school attendance to a minimum age of fourteen and compulsory part time attendance up to the age of eighteen. These two proposals affect every child. Besides this, secondary education is put upon a new footing, and the entire cost to the nation of the reforms will be considerable.

Some rather interesting and arresting appeals are being made in the public press to ensure the passage of the bill by unanimous consent of the people.

Influence on Engineering Industry

The following extracts from this material have a force and meaning outside the precise subject and will bear publicity for their own sake. They are published by the Manchester firm of Tootal, Broadhurst, Lee & Co., and it speaks well for industry when so prominent a firm has the public spirit to circulate such apepals broadcast, and so deprive industry of child labor and remove a long-standing reproach in the textile trade of Great Britain:

"Reason is always on the side of right."

"The State can no more misuse the minds of its children with impunity than a man with impunity can starve a hoist or neglect an engine."

"Just as the force and power of an engine must be directed by a trained man, so the energy and strength of a man must be directed by his trained intelligence."

"The battles of the future will be industrial battles."

"Nothing is to be gained by a good conceit of ourselves or a round abuse of our rivals. One thing only is inevitably sure, and this is that in the rivalry of industry the best man will win. It is Nature's law."

"The best man is the most intelligent man."

"The future of the world belongs to the democracy, which is the most rich in education and mental efficiency, which is the most strong in moral power, and which is most vitally conscious of life as a blessing. The manufacturer who uses bad machinery is beaten by the manufacturer who uses good machinery. The bad machine may be handled by a genius and the good machine by a fool, but the bad machine will never be as efficient as the good. The machinery of the modern State is its democracy."

Citizens Should be Self-Achieving

"It is in the highest interest of the State that all its citizens should feel themselves capable of achieving betterment. No worker can be really interested, whatever his wages or the conditions of his employment, if he feels that this vital instinct has been frustrated in childhood.

"Education should mean the nation's wise development of each citizen's whole nature. It should not only enable a man to improve his fortune, but to enlarge his interests. It should not only provide the citizens with a chance of getting on in the world, but give him a more interesting world in which to get on.

"Nearly all our social problems can be traced back to ignorance. Almost all the unrest of modern times may be traced back to the feeling of the individual that his instinct for betterment has been frustrated.

"The tremendous industrial rivalries of the future demand that we shall have as few social problems and as little unrest as possible."

Contemporary Effort

It is, of course, also known that contemporaneously with huge military effort Great Britain is putting forth equally great efforts not merely in industrial production, but in industrial reconstruction. The war has laid many a prejudice to rest and a new social order is appearing. It will be impossible to resurrect past conditions and equally futile to remain under the industrial conditions imposed by war. As a consequence great strides forward are being made in industrial ideas and in trying to solve the one outstanding problem of every democratic country—that of labor.

The measure of success attending the new ideas may not be commensurate with the thought and trouble involved, but a revised system of education open to all and sundry will have an important bearing on the future.

The heritage of freedom should be enhanced intelligence and a new conception of life and ideas; failing training and education, both are impossible. Among the many new proposals for the stability and settlement of the future industrial era, none promise more than new educational ideals, and labor everywhere is well advised if it supports the widest possible scheme of education, for it is the one certain road whereby the newer generation start with equality of opportunity, which is at all events the beginning of individual equality.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

ALL-STEEL BENCH DRAWER

THE all-steel bench drawer illustrated is designed to meet the needs of those whose requirements do not demand the wooden back, bottom, and front of the frictionless type built by the New Britain Machine Co. The hem of triple thickness around upper edge and the welding of all joints combine to produce a drawer of remarkable strength and durability.

ALL METAL TOOL DRAWER, SLIDE AND COVER.

With the common type of bench now almost universally used, having a thinner back plank than front one, an open space is left between the back plank and the ordinary type of drawer which invites pilfering. In this drawer however, a solid sheet metal top prohibits any tampering at rear and prevents blocking or a lockout through wedging of contents. In addition it serves to exclude any oil or water that might by accident soak through from above.

The slide ways are integral with the top and give to the drawer a smooth, free movement without binding or cramping tendency. The handle is of generous size with a shape of special design which affords a very comfortable handhold. A cylinder lock of good grade with two individual keys is provided. Master keying, if desired, may be had at cost. The possession of master key by foreman will prevent the stowing of contraband in drawers.

The drawer is sold as a unit, requires no fitting, and is easily and quickly installed without any cutting of bench. To apply, the two stops are removed and the drawer pulled completely out from slide ways. After fastening top to underside of bench with wood screws, insert drawer and replace stops.

INDUSTRIAL HOIST

The Albro-Clem Elevator Co. of Philadelphia have recently placed on the market a one-ton direct connected electric hoist, for warehouse and dock work.

This is a self-contained hoisting unit and embodies a primary worm gear reduction having a steel worm and bronze wheel running in oil, and a secondary internal spur gear reduction in the main drum.

The hoist is driven by a 5 h.p. electric motor, direct connected, which is furnished for any system of current.

The line pull or capacity on the main drum of this hoist is 2,500 lbs. at a hoisting speed of 40 ft. per minute, or the machine can be furnished for a line pull or capacity of 1,500 lbs. at a hoisting speed of 80 ft. per minute.

All control of this hoist is by one lever, which controls all operations of starting, stopping and holding the load.

The brake is automatic electric, and is capable of holding any load up to full capacity in any position.

This hoist comes with a cord and attachment plug so that it can be set up and put in operation without any previous arrangement.

This is a very convenient type of hoist, and with it a great deal of work can be accomplished with unskilled help.

FILING MACHINE

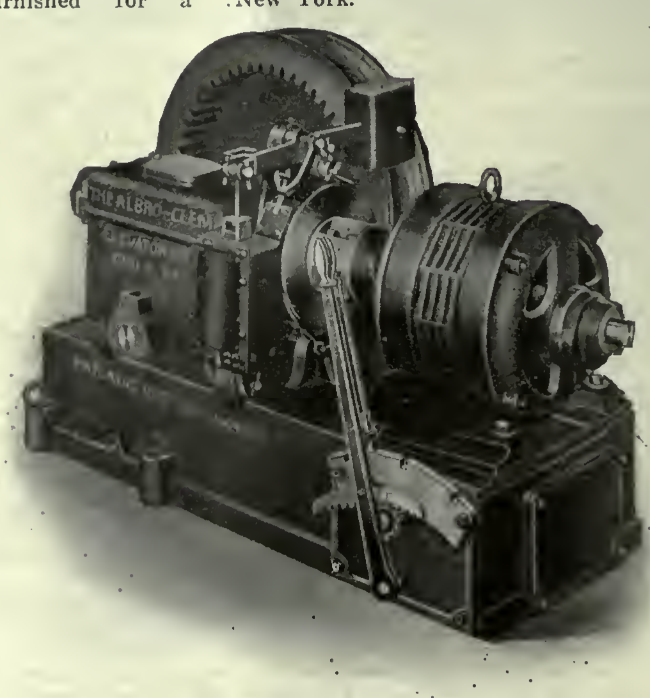
A filing machine which effects a considerable saving in the cost of filing and results in more accurate work is shown herewith.

A square tempered steel spindle is accurately ground and fitted into hand-scraped adjustable boxes, which hold the file in a rigid firm line without possibility of twisting.

The spindle is constructed with ⅜-in. hole to receive files with ⅜-in. round shanks, or any file may be used by grinding the tang so the sides are parallel and forcing it into a hole in a short piece of ⅜-in. rod. The stroke is adjustable from 0 to 2-in.

The table is adjustable to any angle required and quickly locked. The driving shaft is supported by an outer bearing. All working parts are enclosed in a dust-proof case with oil cups for all bearings.

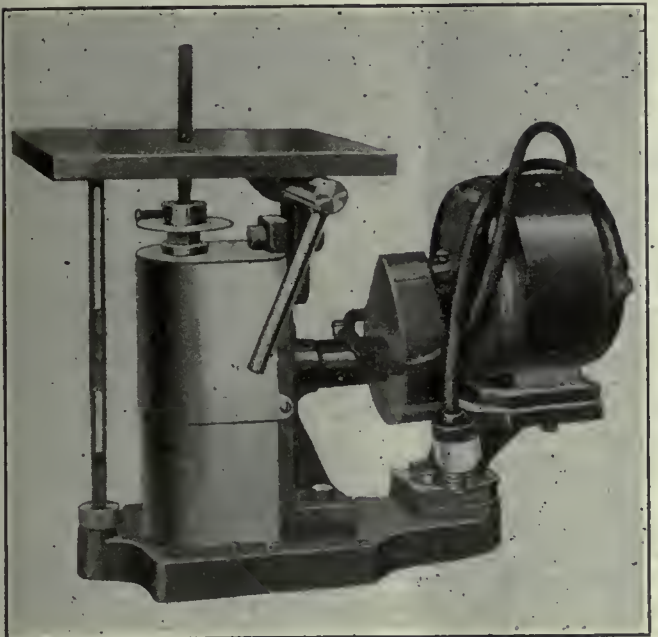
This filing machine is manufactured by the W. F. Davis Machine Tool Co., New York.



WAREHOUSE AND DOCK HOIST.

GERMANY NEEDS RAW MATERIAL

The growth of scientific knowledge with its resultant influence on the development of industry has caused a gradual and increasing appreciation of the value of raw materials—it is now beyond doubt that the intensive industrial efforts of Germany, while primarily intended to aid in the domination of the world, also pointed out the absolute necessity for control of raw materials as a primary step in the programme.



FILING MACHINE.

Now that the sands of time and the hand of fate are giving some indications of final events it is interesting to study the attitude of the German mind and an article by Prince Du Loewenstein Wertheim Frenderburg in *Die Wirklichkeit* is illuminating as showing the important part which raw materials played in causing the war and will play in the settlement

An Empty Storehouse

After the war is over, he says, the German Empire will resemble a great store which has sold out its stocks. In the first three years of war, goods, most of them raw material, to the value of $4,000,000,000 were prevented from entering Germany. There is an absolute shortage of everything "from cotton to sulphur, from seal bacon to platinum." That shortage is a serious danger, for it stands to reason that just as a man out of breath cannot run, a pumped-out state cannot engage in a new war. She must first of all get her breath.

The prince thinks it probable that a new war will follow the close of the present war. "Does anyone imagine," he asks, "that the peace will bring with it sudden quiet? Our statesmen cannot tell. Hitherto they have not been very reliable augurs. This war has surprised them, notwithstanding a hundred warnings. Our statesmen had dreamed of work brotherhoods, and then war came. One lesson we have to learn—to be on our guard. We must cast away our amazing sentimentality—this dangerous inheritance of the Teutonic race. We must see things as they really are."

Prince Loewenstein points out that at the conclusion of peace things will be no better so far as raw material is concerned unless steps are taken beforehand. Even should peace open every market in the world, it would not prevent the wildest competition for raw material and food supplies. Every cotton spinner will struggle to obtain a quick supply of cotton, every gardener will strive for seeds, every farmer for oilcakes. English and German, French and Austrian, all will madly struggle for supplies. And those who in war were allies will be economic enemies on the markets.

Want Materials, Not Money

"The spinner must have cotton if the homecoming textile workers are to have employment, and if he is to pay his burden of taxation. What will happen when these millions return from the front and cannot be employed because of the lack of raw material ? We must not rely on the possibility of obtaining supplies simply by paying for them. Money will not bring in the goods, and will foreign countries accept our paper? Besides, tonnage will have sunk to the very lowest. Against these inevitable economic catastrophes, which in certain circumstances can be almost as destructive as war itself, there is only one possible course—prevention."

The scheme of "prevention" is thus developed. "The victors in the great war, that is to say, the Central Powers, must insert this condition in the peace instrument: 'We demand a portion of the war indemnity in raw material, and this immediately and before other powers have been supplied.' The victors must be the first to eat. We thus get our goods through the State. These goods are given over to our industrials, to our farmers, traders, etc. In this way the State would fructify all necessary channels in a way hitherto unimagined and, besides, in this way we gain a good start over all competitors among foreign nations."

Raw Materials a Cure-All

Prince Loewenstein shows how Germany in this way could re-establish its national economics and avoid the catastrophe of unemployment, exorcise the spectre of want, and banish all danger. The manufacturer gets his material, the farmer his fodder, the trader his goods, the workman his earnings, the people their food, and the State its indemnity.

"England must supply tin and wool, and as for Colonies like Canada, it must yield us copper, nickel, cobalt and leather. Australia must produce spelter, wool, grain and frozen meat, and other colonies jute, leather, fats and oils, rubber, rice, tea, cocoa, etc. South Africa will supply us with gold, and Egypt, should it still remain under British rule with cotton. France will give us olive oil other oils and wine and Algeria will give us cork and phosphates. Italy will supply vegetables, sulphur, raw silk, hemp and oil, and from Russia wheat, barley, flax, oilcake, leather, eggs, platinum and bismuth."

This process of indemnification must continuous until the entire indemnity, as far as possible, has been paid. "It is only in this way and by such means that the war and its consequences can be changed for us into a source of blessing which will again raise our land and people to their old height, which will save them from the abyss of want, from crushing taxation, from mass emigration. Destiny compels us to take these steps, and we must take them or perish. It would be a crime were we to allow false magnanimity or a palsied will to prevent us utilizing our victory to the full. If we neglect this opportunity all eternity will never give us such another chance."

CORROSION IS accelerated by the contact of dissimiliar metals. As a single metal in the annealed and cold-worked conditions differs in its electrical properties, the contact of the two favors corrosion, so that a metal which is locally cold-worked is particularly likely to corrode. For this reason the corrosion of a cold-rolled metal takes place in such a way that the rolling lines become clearly visible, pitting or groves appearing in a direction parallel wit that of rolling.

SOMETIMES cracking is started by superficial corrosion. the corroding agent separating the grains of the surface layer. acting in the same way as a crack. At the same time internal stresses may increase the liability of corrosion by opening up cleavages in the grains, thus effecting a path along which the corroding agent may enter, even though the stresses may not have produced any cracks.

SILVER ARTICLES that are badly tarnished should be treated first with alcohol or other lacquer-remover, then treated with cyanide to remove tarnish, rinsed in water, dried in sawdust and lacquered.

HIDDEN DANGERS

THE extent to which enemy inspired incendiaries and sabotage has prevailed in the United States has been so much greater than in Canada that many of our plant owners may have permitted themselves to be bullied into a false feeling of security.

The great scale on which certain war contracts were carried out by American firms, particularly in the manufacture of explosives, offered very many opportunities for outrage by enemy agents, and, in view of the God-forsaken conscience with which the Hun nation is afflicted, the wonder is that the destruction of plants has been so small.

Much good work has been done by United States authorities in dealing with the danger by means of counter-propaganda, and they have also compiled summary of precautions which everyone can take.

An ounce of prevention is better than a pound of cure, and precautions against enemy damage are just as essential as precautions against fire, contagious disease or any other known and avoidable danger. Despite the care and knowledge displayed in the erection of war time factories, there are always some few things which need adjusting after work is started and many of these involve a high degree of tact and good administration before they are finally disposed of.

Despite the presence of foreigners in considerable numbers, Canadian plants have been almost entirely free from organized effort at disturbance. The comfortable circumstances in which many well-behaved aliens have been able to maintain themselves have convinced them of the golden value of silence, which attitude may have been further induced by lack of opportunity and absence of contact with official agents. Such conditions have doubtless tended to weaken the desire to destroy which is such an ennobled Hunnish virtue, and many aliens in Canada who might at one time have been carried away with reckless admiration for the Kaiser are not now disposed even to sacrifice their job for him let alone get a jail term.

A systematic survey of conditions across the line has resulted in a distinct line of organized effort by the manufacturers. Employees are divided into four classes: Native-born, naturalized citizens, friendly aliens and alien enemies. Certificates of naturalization are looked at askance and something more convincing than the desire for a job is now necessary to secure citizenship papers.

An analysis of the plant should be made, accompanied by a map so that vulnerable spots may be located and indicated. Where will a fire do the greatest damage, where is waste accumulated, what hydrant is most vital in extinguishing a fire, where is the control of the lighting system, where will an explosion cause the most damage, what machines are most vital or difficult to replace, where can goods in transit be tampered with easiest? These and many other suggestions will occur when being considered.

An equally important feature is the kind of men in charge of these points. Germany waited forty years to start the war and her agents may be expected to wait just as patiently to finish it. The Hun has shown that he does not expect to escape destruction and wishes all others to share his fate with him. Unless the loyalty of all men in responsible positions is absolutely unquestioned, the possibility is always present that they will "keep mum" until the final chapter and then let loose a program of sabotage and crime which will be appalling. This possibility cannot be overlooked with impunity no matter how clear a man's record. It is part of their job to remain above suspicion.

The protection of important machinery and plant by isolation is a problem that has received much attention and wire fences, barred windows and armed guards abound with a frequency which is now accepted as a matter of course. No sane visitor expects to get through important plants with the ease and freedom formerly existing but it is the manufacturers' duty to see that innocent appearing workmen do not gather information in the course of their work which would be withheld from personal acquaintances of the firm. Inconsistency in this respect involves a degree of risk which is not realized as it ought to be.

Finally, employees should be treated so that no grievance remains unadjusted long enough to become a sore. Works must be fool proof as well as bomb proof and any slight disagreement may develop overnight into a dispute which may only be settled after a strike and other events have wrought their damage through delay, increased cost and other difficulties which mitigate against the winning of the war.

Delay is bad at any time, just now it is dangerous as well as expensive. See that your employees are proof against it.

REMOVING OUR BURDENS

THE hope for meeting the burdens which the war has placed upon us in the way of interest obligations is in the production of goods which will utilize our natural resources and which can also be manufactured with our present resources and marketed with more or less facility.

The attitude of Canadian manufacturers toward export business has been the subject of much discussion in recent months, and in view of disparaging remarks from some parties it is interesting to note that the Canadian Bank of Commerce has not grounds for attributing to Canadian manufacturers reluctance to enter foreign markets.

Discussing the impression that a foreign buyer is not as reliable to do business with as a domestic customer, the bank referred to declares this to be erroneous—"It is true that the foreign importer frequently seeks time on his purchases, so that if our exporters hope to secure orders in countries where it is usual to allow 30, 60, 90 or 120 days on purchases, credit must be granted in accordance with the prevailing custom. Credit risks must, of course, be carefully scrutinized in the foreign markets as in those at home, but the banks and mercantile agencies are only too pleased to secure reports on foreign traders and to place their facilities at the disposal of all shippers. . . A great many of our exporters are inclined to insist on cash with the order or cash on production of the documents at the shipping port, but little can be gained in endeavoring to develop an export business along these lines. . . Other exporting countries have seen fit to grant reasonable credit where conditions warrant it, and if our exporters hope to succeed in their foreign endeavors they must at least accord similar terms; otherwise the business will go elsewhere."

FARMERS HEAD THE LIST OF CAR OWNERS

Have It on the Skilled Trades by a Two to One Shot—Some Particulars

WHEN an old gas bus of the vintage of 1907 or so wheezes by the chances are that you turn around and murmur "Ice." Or else you give some person a nudge and say "Some boat that."

Yet the old cars that ambled around in the days of 1903 had a place in the motor world that the super-six can't crowd into now. The gas wagon that came into existence when there were only two or three to a town was a centre of admiration. The man who owned it was a greater man than the chap after whose grandfater the main street was named, and almost on a par with the deacon who tapped the corner stone of the new church with a silver trowel.

Motor cars were first licensed in Ontario back in 1903. In that year the honor roll of horse scarers contained the names of 220 guilty parties. The horse in 1903 that couldn't put its hind legs over the dash board at the opproach of a car wasn't worth wasting the pasture on.

In 1907 the registration included 517 cars owned in Ontario. The following figures tell the growth. Take the difference between 1916 and 1917. Of course it's war time and people aren't supposed to have any money for cars, but have they? Read the figures:

1917—	
Passenger car registration	78,861
Motor truck	4,929
Total	83,790
1916—	
Passenger car registration	51,589
Motor truck	2,786
Total	54,375
Increase in 1917	24,486

Of course the farmers aren't supposed to be making any money. It's just as hard a job to get a farmer to admit that he's making money as it is to get an editor to admit that he's not writing good stuff all the time.

Well now, working from the point that farmers are not making any money, let's see where the figures lead us. You'll have to do a heap of explaining to make them jibe with the hard luck story. Here they are:—

Farmers	23,409
Skilled Trades	10,937
Merchants, Manufacturers, etc.	14,825
Physicians	2,605
Other professions	3,394
Commercial Travellers	1,079
Taxicabs	1,662
Miscellaneous	20,950
Total	78,861

It is also worthy of note that the small truck, the delivery type, is by far the most numerous. The figures are:

Ambulances, etc.	41
½-ton trucks	2,072
¾-ton and 1-ton trucks	1,563
1½-ton and 2-ton trucks	513
2½-ton trucks	24
3-ton and 3½-ton trucks	575
4-ton and 5-ton trucks	118
6-ton and up	23
Total registration	4,929

Here's a Bit of a Sermon

HE went one day to get a job, he had to earn some cash, to pay his laundry ticket up and square his bed and hash. He had his nerve ten feet in length, of chest he had a heap, he wasn't lackin' not a bit in big hunks of conceit.

He wasn't goin' to do a job where he would soil his fist, or cause a spot to camp upon the watch upon his wrist.

He didn't want to swing a pick, nor drive an Irish lathe, or be a sewer digger and camp within a cave. He wanted cash for all he did, of that there was no doubt, but he didn't want to get hooked up with too much work about.

He knew about a drill he did, he knew about a file, the things he knew if stacked on edge would make up quite a pile.

He worked one year upon a farm, he used to drive a binder, he knew about a lathe, by gum, likewise about a grinder.

He'd seen a man who had a son, and this chap had been told about another friend of his who knew just how to mold. He'd often watched a smithy work about the dust and heat, and seen him nail the boots upon the Clydesdale horses' feet, and so he knew about this job, he learned by observation, but not by rollin' up his sleeves and not by perspiration.

And every time he got a job he lasted half a day, they always reached to tie a can on this here reckless jay.

There's a heap of truth in this here yarn, if you will flop your ear, and dip your head across this way so you can't help but hear—don't try to jump around and make a hopeless, foolish dazzle, but pick one job and then, me boy, just lick it to a frazzle.—ARK.

MARKET DEVELOPMENTS

Pushing the Sale of New Machinery Now

Dealers Find it Gives Better Satisfaction—Fabricating Plants Are in Reality Working on a Warehouse Basis Now—Plating Chemicals Advance Regularly Now

WAR time trade makes new grooves, and it is surprising the way in which Canadian business firms fit their lines to these channels. For instance, several bridge and fabricating plants are now, to all intents and purposes, in the warehousing business. They send out stock lists regularly to the trade, and the trade is glad of a chance to get supplies from their large stocks, because they have many lines on hand that are not being rolled at the mills either in Canada or United States at present.

Steel jobbers have numerous searchings in their efforts to fill orders sent to them. In many cases the parts for which their searches are being conducted are standard lines, and in normal times there would be no more trouble in securing them than in buying tea at a grocery store. An order for beams, for instance, is likely to cause quite a bit of farming out before all the sizes are located. Jobbers in nearly every case are working well together, and in this way orders are made ready for shipment, which would otherwise be an impossibility.

There is a tendency, and a considerable one, too, to purchase new instead of second-hand machinery. One of the largest dealers in this line stated this week that his firm was discouraging trading in second-hand machinery, and their experience was that there were better results for all in the new machinery trade. As a matter of fact there is not a very large amount of used machinery coming into the warehouses. About the only notable exception to this is part of a Hamilton plant that is now in the warehouses of a Toronto firm, following the completion of a munitions contract.

Price advances have been few during the week in general lines. The one exception to this might be in chemicals that are used in plating. There are price revisions almost daily in these lines, and it is almost impossible to keep a list at the point where it can be called correct in every detail. Prices for much used in plating work are at abnormally high levels, and there does not appear to be any good sign pointing to a let-up in the tendency of high value. Against this it is interesting to note the manner in which some steel products have kept to their level for months in the fact of keen demand and difficulty in securing supplies. There has not been, for instance, a change in the prices quoted on Canadian steel bars at the mills for over nine months, and indications are for the present level remaining.

American producing points are running well. The hot weather is going to hurt production at the open hearth furnaces, blast furnaces and rolling mills. But they have been for some time now giving a production performance of well over 90 per cent. The scarcity of good scrap metal is also hindering the best results at the open hearths. Heavy melting steel is also in great demand, but the supply is not good, and whatever comes on the market is quickly taken up.

Prices on second-hand copper and brass are stronger on the Canadian markets this week, again following the lead of the higher fixed price in U.S. for copper.

POOR QUALITY OF SCRAP HINDERS THE LARGER PRODUCTION AT U.S. POINTS

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., July 17.—The partial report of the production of steel ingots in June indicates that the total production in the month was at the rate of about 42,860,000 gross tons a year, against rates of 42,960,000 tons in May, and 42,930,000 tons in April. Thus there was a slight decrease but that is splitting hairs. The general position is that since early in March, or after the recovery from the great curtailment of the winter, production has been at a practically uniform rate of about 42.900,000 tons a year, or 90 per cent. of the full capacity. That the other 10 per cent. production was not realized was due to the trying conditions existing, a little shortage of labor, in point of numbers, a little slackness in labor performance in many quarters, unusual difficulties in making repairs and, most important of all, the poor quality, on the whole, of the scrap available and some shortness in the total supply.

There is no shortage of pig iron of any consequence, though there was a very severe shortage in the winter. Output would not be increased, but would rather be decreased, by the open-hearth furnaces using more pig iron and less scrap. What they would like is a scrap of better quality, more heavy melting steel so that they would not be driven to use so much indifferent material, particularly steel turnings.

Thus far in July the weather has been extremely favorable, for the season, but some curtailment in output this month and next is certain on account of the heat. This may be made up by better operations in September and October, but in general the production rate of the last four months indicates approximately what is to be expected for the remainder of the year. The rate is just a trifle better than the average rate of 1917 and a shade better still as compared with the 1916 output.

Distribution of Material

Recently the War Industries Board prescribed some additional regulations for the distribution of pig iron and steel products, and as there is not likely to be any further important change in the regulations it may be of interest to set down precisely the manner in which material is to be distributed. The sequence is as follows: Priorities AA, A and

B; Class C, preference material; Class D, permit material.

The priority certificates are precise in that they call upon a producer to furnish to a consuming activity a precise quantity of certain material. As a rule the material is material required for a strictly direct war use. The producer is not required to ship against all the priority certificates furnished him be fore he does anything towards shipping Class C material, but he is required to provide for filling such priorities with the greatest promptness that seems necessary.

Class C material is material coming under the "schedule of purposes entitled to preference treatment" prescribed under date of June 6th and subsequently modified slightly. The list starts with ships and ends with public utilities. The precise distribution as to quantities, etc., is left entirely to the producers. They are supposed to know, or ascertain, the exact use to which a customer will put any lot of material.

Class D material is what is left. A shipment in this category can be made only upon permit, secured from the Director of Steel Supply upon applica tion by the producer, not the buyer. One exception is made, a blanket permit being issued covering any shipment not over five tons, with this proviso, that at the end of the month the producer must report each individual shipment of this character with a statement of belief hat the shipment was "in the public interest."

Thus the system prescribes that one great class of material, Class C, shall be distributed by the producers after their own fashion, simply following strictly the general regulation laid down, as to the sequence of the "purposes" for which the material is intended by the buyer. On the one hand, however, there is material the producer is required to furnish, through the priorities, while on the other hand there is material which cannot be shipped at all except by permit. Thus there is one general flow of material, with certain exceptional material forced and certain other exceptional material restricted. Theoretically it looks like an excellent system, with a minimum of red tape and a maximum employment of the producers' knowledge of the trades they undertake to serve. Practically it is the common testimony of the producers that it is working very well.

The War Industries Board is endeavoring to reduce the volume of priorities extant by granting from week to week less than are filled. Apparently its particular activity in this direction is to seek to have the various Government departments reduce their applications for priorities, there being reason to suspect that more have been called for than were really needed. Thus as time passes there should be more material for Class C, and eventually perhaps more flowing over into Class D. Whether permits in the case of Class D will be granted freely or reservedly experience does not yet show, except that it is the testimony of some producers that the War Industries Board is quite reasonable in considering individual cases, without an undue reverence for the strict letter of its general regulations.

The Jobbers

The case of the jobbers has been settled, and apparently in a way that gives them about all they could have asked for. They are required, on the one hand, only to furnish material from stock according to the same rules as obtain with the manufacturers with respect to the preference list, and to report shipments so that they can be checked according to the regulations, but on the other hand they are assured replacement, from the mills, of all material thus shipped. Inasmuch as the jobbers for the main part have faily large stocks, they should be able to get along rather comfortably. There is, furthermore, to be some replacement of material hitherto supplied for war activities.

Prospects of General Supplies

Consumers whose activities are covered by the preference list need have little concern as to supplies. Those given no general recognition, but who can obtain deliveries only by the producer securing a permit, are likely to receive little for the time being. Instances are multiplying, however, of important war activities becoming well stocked with steel, whereby in individual cases they will not require shipments to be continued indefinitely at the rate of the past two or three months. In some cases mills have already been instructed to divert shipments to other consumers in the same class of activity. Some forge shops making shell blanks, for instance, have become loaded with material, also some fabricating shops making ship parts. Diversions to other shops may in turn give them an ample reserve. Accordingly, in some quarters it is argued that as time passes there will be more material flow over from the lowest items in the preference category, into Class D.

POINTS IN WEEK'S MARKETING NOTES

As evidence of the volume of business in the New York machine tool market, we are advised that inquiries this week represent $25,000-000 worth of business, allowing for all shrinkage.

The demand for cranes is so heavy that some shops are booked far into 1919 with this sort of business.

The supply of scrap reaching American open hearth furnaces is of a very inferior sort. There is no marked shortage of pig iron at the steel mills now.

The arrival of the hot summer weather is almost certain to have the effect of curtailing the output at the rolling mills and furnaces.

The Baldwin locomotive works is to build a new locomotive plant at Chicago. It will call for 12,000 tons of steel.

Dealers are pressing the sale of new machinery to a greater extent than ever, claiming that a more satisfactory business can be done this way than by handling used machines.

Plating chemicals are again on the rise, the advances in some lines being quite marked.

The prices on bars at Canadian mills are making a unique record,in that they have not advanced for the last nine months.

Several bridge and fabricating plants are almost in the warehousing business now, selling out their stock to the trade. Their usual line of business is at a standstill, and the mills are not rolling many of the lines with which they are well stocked.

Scrap prices on brass and copper are advanced, following the higher fixed prices granted by U.S. war board for copper.

FIRM DENIES MANY RUMORS AFLOAT

Lymburners Use Full Page In Regard to Accident at Their Plant

Lymburner, Ltd., Montreal, had an accident in their plant on Saturday morning, when part of the third floor collapsed. Five names are given as the casualty list. They are Henry David, Napoleon Prevost, Amade E. Thibeault, Joseph Beaudoin and Joseph Boyette, all of Montreal. Apparently there were so many wild statements made about the accident that the management considered it necessary to officially contradict them a full page, signed by E. Halley, vice-president and general manager was used in Montreal papers for this purpose, and stated:

To correct the many false and unfounded rumors that were falsely circulated in connection with an accident that occurred at our plant this morning: Lymburner, Limited, situated at 360 St. Paul St. East, makes this full page announcement in the *Standard*: There is always a certain class of people who like to talk in a sensational manner and who are therefore very often more detrimental to society than they are useful, and it is those people alone whom we hold criminally responsible for the sensational manner in which sensational news travels, and it is to the public and our business associates that we say: "Our plant was not wrecked in any manner, shape or form, and that the loss of life was not as sensationally reported. "We wish to state to our business associates and business clients that business is going on as usual."

FEAR OF TRAFFIC TIE-UP IS THE WORST FEATURE IN MONTREAL NOW

Special to CANADIAN MACHINERY.

MONTREAL, July 17.—Considerable interest is at present centered in the possible developments of the next few days, regarding the attitude of the railroad shipment towards the ruling of the Railway War Board, respecting the wages and working conditions of these employees. Unless the next 24 hours develops a more encouraging tone, the transportation problem will become one of the greatest yet experienced. Recent conferences have failed in securing a satisfactory solution, as the men are determined to stand solid for their demands. Should a strike result, the early collapse of traffic would undoubtedly follow, as deferred repairs to rolling stock and mechanical equipment would be followed by a virtual tie-up of transportation.

No additional contracts have been placed for shells but firms that have recently obtained orders are changing over or otherwise preparing for production operations. Several new plants are about ready and others are progressing rapidly. Metal markets are operating steadily but activity is normal.

Steel Steady

The feature of the week is still the activity that marks the shell making industry. Renewal of orders has revived many plants that during the past year had practically stopped or greatly curtailed operations.

The return of the 9.2 size to local production has resulted in further forging operations. The Canada Cement are again making forgings for this size and anticipate machining in the near future. The Dominion Bridge are preparing to utilize their 6 inch forging equipment for the production of 9.2 shells, machining operations on which will be done by the St. Lawrence Bridge Co. Various plants are now forging shrapnel and work on this type of shell will soon be progressing on last year's capacity.

General steel conditions throughout the district show little change, dealers reporting nothing of special character. Priority regulations are somewhat relaxed—in form—but the possibilities of acquiring steel for other than essential purposes, remains a contending factor. With the advent of the hot weather it is anticipated that steel mills will be somewhat effected and a consequence production is expected to show a falling off. Importation of coal is well maintained but in many cases the lack of shortage facilities makes it difficult for some interests to prepare for future eventualities. One dealer here reports the movement of fuel to be very good but looks for some scarcity during the coming winter.

Metals

Apart from the continued uncertainty prevailing in the tin situation the general metal market is one of steady but featureless activity. Copper has steadied following the recent advance. Business in tin is still carried on under a cloud of uncertainty. Activity in the other metals is normal with no price changes to repart.

Copper.—Local interest has again resumed a normal character now that the tension of uncertainty has been removed by the recent revision of the price of this metal. Dealers report a steady business but almost the entire volume of metal disposed of is intended for government or other essential industries connected with war requirements. One local firm is doing a very extensive business in the brass and copper tubing and their needs are at present quite large. Dealers here have recently rvisd their quotations to meet the changed conditions at the source of supply. The new prices, which went into effect last week, are on a basis of 30 and 31 cents.

Tin.—The situation here is still one on which the dealers are unable to throw any clear light, so that present operations are carried on, more or less in the dark. Dealers report steady sales for immediate requirements but are unable to supply tin for definite future deliveries. Spot tin is scarce and visible metal is uncertain. Dealers are still quoting $1.10 per lb. but the tendency is upward.

While the new demand for machine tools is not exceptionally heavy, the enquiry for all classes of equipment is well maintained. Many plants that have been preparing for the manufacture of American shells are busily engaged in acquiring machinery and good progress is being made on installation. The new 155 m.m. shell plant of Caron Bros. is about completed and tools are now being placed. Several other local firms are waiting on equipments that has been ordered for some time. One dealer reports that considerable enquiry for equipment has recently developed from American sources but definite action has been delayed. One local machine builder has already disposed of considerable machinery to American buyers. Sales of accessory supplies are very active, particularly in relation to munition plant requirements.

Scrap Metals Stronger

Apart from the passive interest that has been shown in the advance on old copper and brass scrap, caused by the recent revision of the refined metal price, the market is devoid of special feature and dealers report a condition that is otherwise unchanged. The local advances confined to copper and brass scraps, the former showing a one cent and the latter from ¼ to ½ cent advance. Present quotations on old copper range from 20 cents for light to 23½ cents for heavy and wire. Composition turnings are quoted at 22½ cents per lb.

AFTER THE WAR WILL BE THE TIME TO EXPERIMENT ON STANDARDIZATION

"I believe that standardization can be attempted to much greater advantage in certain lines in times of peace than in times of war," stated a well-known designer of machine tools to CANADIAN MACHINERY to-day. "There is a lot of talk being done on this but when it is all ironed out I can't see where it amounts to a very great deal.

"The one thing we have to keep in mind at all times is that this war is not a permanent affair, and the element of haste is perhaps the greatest thing that enters into it. We might be able to turn out something very fine five years from now, but what are the Germans going to do in the meantime. They are certainly not going to sit down and crack their heels waiting for us to turn out some standardized form of equipment to fight them with. I'll grant you that it is much better to have a machine gun than a club when you go to war, but if you have not got the machine gun would you refuse to use the club? Perhaps that's a bit homely as an illustration, but I think you will see my point from it."

In the Motor Works

"Where would standardization work out to the best advantage?" inquired this paper.

"Well, that's a pretty big question and it would stand a whole lot of answering, but it seems that the best place for this to be worked out might be in the airplane motors and in heavy trucks. The latter would be preferable because I don't think it is possible to make a standard motor for airplane work that will be efficient in the months ahead of us. There are so many types of planes for different work that it seems hard that we should get one power plant for them that would be equally successful in all. People are making the same mistake here as they make in the States. They get the Henry Ford plant idea in their head, and they think they will run the whole war machine on the same standardization scheme that Ford has used to make his car the success it is. There are two things that kill that idea and they are (1) that bulding autos and fighting the Germans are two different things, and (2) it took Ford almost ten years to get that plant of his lined up to where he wanted it. Then again, the life of much of the machinery at the front is short. They want it quickly and they want a lot of it. We can have all the fire-place conferences we want on standardization after the war, but it seems to me that the thing now is to shove in the juice and get the stuff produced. There's a large amount of 100 per cent. efficiency outside of standardization."

MANUFACTURING NEWS

Volume XX. No. 1. July 25, 1918

GROUP OF BUILDINGS AT ENTRANCE TO PLANT.

THE industrial activities of the last few years have brought about far-reaching advances in almost every line of endeavor. This is particularly true in the metallurgy of iron and steel. The electric furnace is playing an important role in this advance and its development to the point where it can be depended upon for the quantity production of high grade steel such as is required in the government specifications for shell and other munitions of war is of much interest.

The metallurgical processes connected with the refining of steel are now well established and the ability to meet the requirements of quantity production and quality combined with the ease with which scrap steel can be used as the raw material make this process admirable from many points of view. In the open hearth furnace the ratio of scrap to pig iron charged may be as high as 75 per cent. but in the electric furnace it readily approaches 100 per cent. This fact, coupled with the cost of labor will undoubtedly operate to the advantage of the electric furnace after the war.

The scrap resulting from the operation of munition plants serves as an admirable source of raw material for use in the electric furnace, and this, with the adequate supply of power available determines the equipment installed in the plant operated by the Imperial Munitions Board for the British government and described below.

The preliminary work and plans were done under the direction of Col. David Carnegie by Perin and Marshal of New York, and the construction work was let to Roger Mills and Sons of Toronto. The engineering since required has been entirely in the hands of the staff of engineers which forms a permanent part of the organization.

Plant Layout

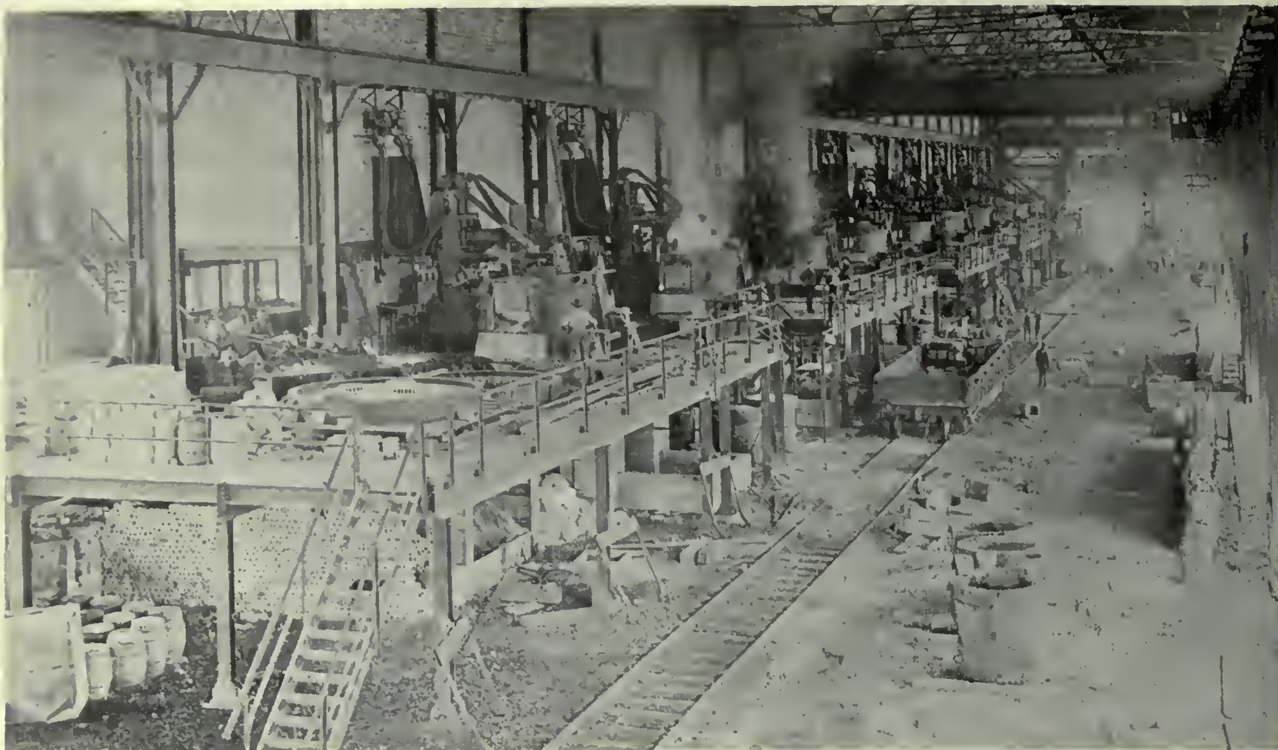
This plant, believed to be the largest electric steel plant yet constructed, is admirably planned with ample facilities for the economical handling of all materials. Standard gauge railroad tracks, about five miles in all provide and serve every individual unit of the plant, in many cases permitting the loading and unloading of the cars under cover.

The various functions of the plant naturally center around the electric furnaces and a major portion of the trackage and equipment has to do with the handling of the raw material, steel turnings. Much of this material is stored in open stock piles in the plant yards and is handled by locomotive cranes equipped with electro-magnets. The remainder is stored under cover in a covered stock pile adjacent to the main furnace plant. This building has a capacity of about 12,000 tons of turnings and is equipped with two ten-ton Northern travelling cranes with 55-in. electro-magnets.

Bays project from the main charging floor out over the stock pile at each furnace, and the 24-in. gauge tilting scrap cars serving the furnaces are loaded by crane, pass to the weighing scales and are then dumped at a point between the furnaces convenient for their hand charging.

As may be noticed in the accompanying cross-section the layout affords ex-

†Associate Editor, Canadian Machinery.



GENERAL VIEW OF MELTING HOUSE SHOWING ARRANGEMENT OF FURNACES, CHARGING AND CASTING FLOORS. A FURNACE TOP IS BEING RELINED AT THE LEFT HAND FOREGROUND.

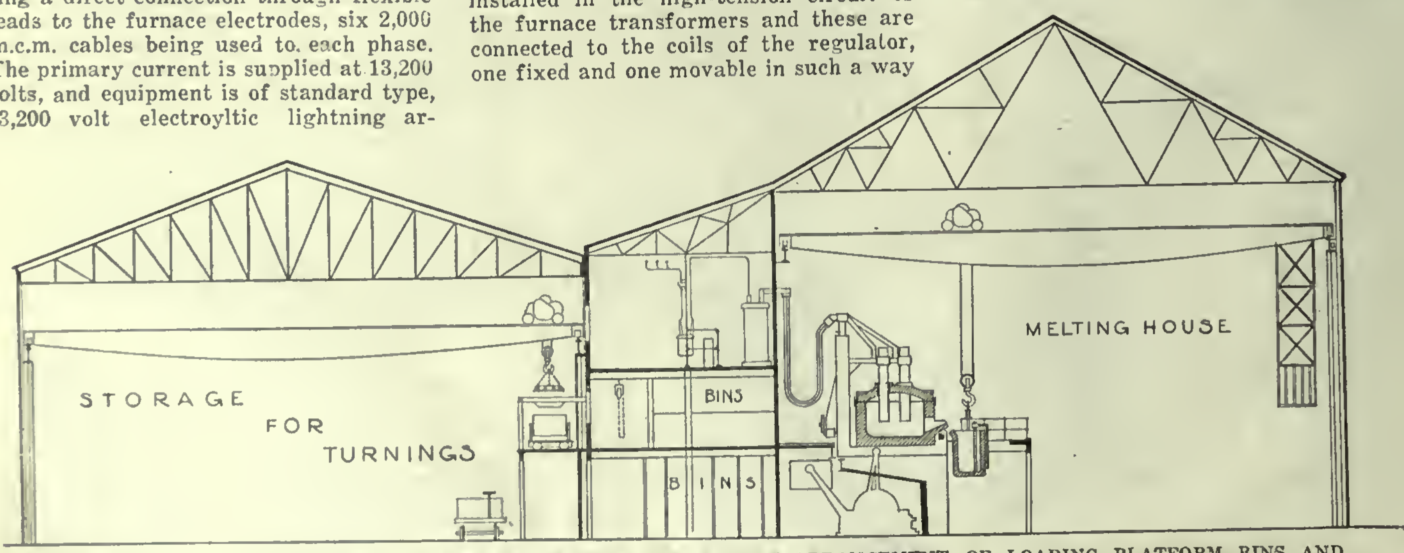
cellent storage space in the lean-to on both the charging and casting floors. This space accomodates the ferro-olloys and fluxing materials used in the various slagging operations. The building in which the ten electric furnaces are installed is 610 ft. long, 75 ft. span, and is of standard mill construction. As above-mentioned the transformers and stock bins are housed in a lean-to 25 ft. wide which runs the full length of the building.

The transformer room is enclosed in hollow tile and is raised above the furnace-charging floor, thus permitting the bins for storing the various materials used in refining to be placed directly underneath and convenient to the furnaces. The three-phase 1,500 kv.-a transformers are located directly behind the furnaces which they serve, permitting a direct connection through flexible leads to the furnace electrodes, six 2,000 m.c.m. cables being used to each phase. The primary current is supplied at 13,200 volts, and equipment is of standard type, 13,200 volt electroyltic lightning arrestors and 30,000 volt oil switches being installed.

Thury Regulators

The Thury regulators common to this type of furnace are mounted in the transformer room while the indicating instruments and winch operating controllers are mounted behind the furnaces which they serve. This regulating equipment supplied by the Westinghouse Company provides automatic regulation of the current supplied to the furnaces and produces a uniformly constant current at the electrodes subject to control by the operator in charge.

The furnace electrodes are raised and lowered by means of a motor-operated hoisting mechanism or winch, the motors in turn being controlled by means of the regulator. Current transformers are installed in the high-tension circuit of the furnace transformers and these are connected to the coils of the regulator, one fixed and one movable in such a way that when the furnace current is at its proper value the movable coil is held in equilibrium by a spring. When the current rises above or falls below its normal value this equilibrium is destroyed and the coil and the rocking lever to which it is attached are swung one way or the other and thus engage tappets and in turn release pawls which fall into notches in the rim of a tappet wheel which is given a reciprocating motion about its centre. These pawls are located upon a rocker arm which makes contact with either one of two sets of carbon contacts and according as one set or the other of these contacts is made, the winch motor is operated in one direction or the other, thus raising or lowering the electrodes. A rheostat is provided in the current transformer circuit which shunts a portion of the current and provides a means



CROSS SECTION OF TURNINGS STORAGE AND MELTING HOUSE. THE ARRANGEMENT OF LOADING PLATFORM BINS AND TRANSFORMER ROOM IS CLEARLY VISIBLE.

FURNACE TILTED AT THE FINISH OF THE MELT AND STEEL BEING TEEMED INTO LADLE.

of maintaining any constant current value desired.

In a plant of this size it is necessary to provide some means of central control from which switching operations can be carried out. This need is filled by the main control room centrally located between the two sections into which the transformer room is divided. This control room houses the main control switchboards and projects out into the furnace room giving the operators a clear view of the furnaces. The switchboards in this room carry the control and service switches and the recording and indicating meters for the plant load.

Under the main control room space has been allocated to the service equipment needed for the operation of the plant. This equipment is located on the ground or casting floor level and consists of a 60-cell storage battery for the operation of the remote controlled high-tension oil switches, 200 and 300 kw. motor generator sets for 230-volt direct current, an air compressor, oil pumps, etc.

Furnaces

Ten furnaces are installed, all of six tons capacity, and of the Heroult type. These furnaces are located on a charging floor about 12 ft. above the casting floor, the space underneath being given over to the tilting mechanism and the oil burners for pre-heating the teeming ladles. The tilting mechanism is protected from accidental breakages in the furnace lining by a brick-lined steel pan which carries any metal away and into the slag pit. Nine of the furnaces have a basic lining while the tenth is acid.

Heats are poured at short intervals, between forty and fifty being run off in the course of a twenty-four hour day, each heat taking about four hours for its completion.

The control of each melt is a matter of skill and judgment on the part of the furnace operators controlled and rigorously checked by analyses of the steel made during the melt. The laboratory in which these tests are made is housed in a separate building insuring cleanliness and the quiet conditions necessary to accurate work. A balance room is provided where all weighing necessary to the analyses is made.

The steel, when ready, is teemed into bottom-pour ladles, preheated; these in turn serve the ingot molds. The ingot molds of cast iron are of a size best adapted to the shell forging desired and the billets in the case of the 6-in. shell weigh about 200 lbs. Hot tops for the ingot molds are made in the plant, and the care taken in pouring as well as the shape of the ingot molds and hot tops insures the absence of piping except in the crop end. Before each ingot has completely solidified a metal identification tag is inserted in the crop end.

Two methods of pouring the ingots are in use. In one of these the ingot molds are stood on end in rows on the floor, while in other eighty-four of them are mounted on one truck and the truck moved instead of the crane. This results in a considerable saving of metal in the avoidance of splashing.

Four Northern cranes are installed in the melting house each with 15-ton main hoists and a 10-ton auxiliary. These cranes not only serve the teeming ladles but are used for other operations, one of their principal uses being the moving of the furnace tops to a space provided at each end of the charging floor for relining.

Breaking and Cutting-Off Shop

As soon as the ingots are cold they are sent to the breaking and cutting-off shop. This is in a separate building and a feature which has much to do with production first makes its appearance here. Manual labor is eliminated in all possible ways and conveyors adapted to the needs of each particular operation are used throughout. The ingots are carried from the furnace room to the cutting-off shop by means of a link belt conveyor running between the two buildings, and are taken off the conveyor and placed on tables serving the cutting-off machines. Here they are stamped with the melt number and are then picked up and placed in the cutting-off machines, made by the Williams Tool Co. of Erie, Pa. To deal with the ingots, seventeen of these machines have been installed in two rows down the center of the shop and pneumatic hoists are provided which eliminate all manual labor.

The ingots are cut about half way through and are then transferred to another conveyor which carries them to the pneumatic hammer. This hammer breaks

SCENE IN MELTING HOUSE—POURING INGOTS.

BREAKING OFF THE CROP END OF THE BILLETS IN THE CUTTING AND BREAKING SHOP

off the crop end which falls to one side, down a chute, and into a conveyor, from which it eventually finds its way into the furnaces again. The shell billet rolls the other way on to another conveyor, undergoes its first inspection and is ready for forging.

One ingot in each melt is marked with a distinctive paint and drillings are made from this to determine the chemical analysis of the steel.

The two illustrations shown of the cutting and breaking shop give a clear idea of the layout and amount of equipment necessary.

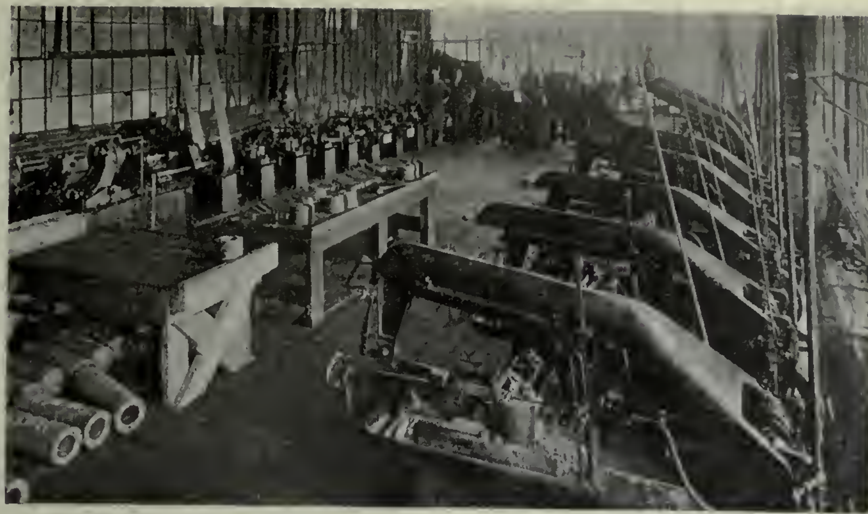
Forge Shop

The forge shop, located adjacent to the cutting and breaking shop, is a spacious steel building admirably planned for the handling and routing of the billets through the various operations. The billets as they are received from the cutting and breaking department weigh about 158 lbs. and measure about 6½ in. average diameter. Each lot as it is received is piled back of the furnaces, care being taken throughout all the operations to keep all billets belonging to the same heat number together, and separate from other lots.

The furnaces, of which there are seven, are of the continuous type, and taking in the billets at the rear end deliver them at the proper temperature at the front. Oil firing is used, the oil pressure being about forty pounds and the air pressure ten ounces. Two underground oil tanks are provided into which the fuel is run directly from the tank cars.

The hydraulic forging presses are five in number and are all of 500-ton capacity made by the Southwark Foundry and Machine Co. A water cooling system is employed to somewhat reduce the temperature of the dies and punches, a perforated pipe surrounding the upper end of the punch. The billets, while passing through the furnaces turn and come to a uniform temperature, and on reaching the front are ready for pierc-

FORGE SHOP—FURNACES AND HYDRAULIC PRESSES.



VIEW IN TEST BILLET SAW ROOM.

ing. The billet is dropped into the die and a centering ring placed on it to guide the punch. The piercing and drawing of the six-inch shell forging are done in one operation, the piercing causing an upward extension of the metal out of the die. The return stroke of the press withdraws the punch and the forging is forced up out of the die by a kicker and is removed and dropped into a conveyor for removal to the cooling beds.

The various heats are still kept separate, and when the forgings are sufficiently cooled they are again inspected, stamped with the heat number, and one or two of them picked at random and taken to the saw room.

These forgings are used for the various mechanical tests demanded by the government. The base is cut off in William's cutting-off machine similar to those in the breaking and cutting-off shop described above and test pieces are sawn out of both sides by a battery of Peerless high-speed saws made by the Peerless Machine Co., Racine., Wis. These saws cut the test piece out at one operation by means of a double saw. Following this the bases are inspected for piping or other flaws and the test pieces are turned down to the proper section for the government test.

GOTHIC STEEL, METHOD OF HANDLING THE BARS PREPARATORY TO NICKING.

Power House

The hydraulic pumping equipment necessary for the operation of a forge room of this size must necessarily be of some magnitude. This equipment is housed in a separate building and from the accompanying engraving a good idea of the layout may be gained. A battery of seven 200-gal. Dean pumps, made by the Worthington Pump Co. are installed. These pumps are geared to 200 h.p., 2 200 volt Westinghouse motors running at 500 revs. per min.

The autor starters and other switching equipment, together with the necessary switching equipment and meters, are installed on the wall adjacent to the motors which they control.

Two 28-in. accumulators of Southwark make are also installed in this building and the oil pumps for the oil-burning system are located near the oil tanks adjacent to the forge house.

VIEW OF POWER HOUSE SHOWING HYDRAULIC PUMPS AND ACCUMULATORS.

Billet Plant for Gothic Steel

One of the interesting features in connection with this plant has to do with the cutting of the bars of Gothic steel into billets of the proper size for forging and the advantages of conveyors in the increasing of production and eliminating labor are nowhere better shown than here. The steel as it is received from the cars is stacked in piles according to heat number, and as required is picked up by air hoists and placed on the gravity conveyor shown in the illustration of the steel yard.

The steel travels on this conveyor to the first position in the cutting-off shop where each bar is marked from gauges to the proper length. The bars next pass on the the same conveyor to the nicking position where they are nicked to the proper depth by the oxyacetylene torch. As shown, two gangs of men work at this position and using torches and apparatus supplied by L'Air Liquide Society rapidly nick the bars on one side to the proper depth of about one half inch. The torches are provided with supporting wheels which render the operation easier to perform.

NICKING THE GOTHIC STEEL BY THE OXY-ACETYLENE TORCH.

After the nicking operation the meit number is stamped on each portion of the bar, and the bars still travelling forward are brought to the horizontal bulldozer, where they are broken into required lengths. The next operation is the inspection, one man being stationed at this point to swing the billets in such a manner that the inspectors may readily view the end again. The billets are next stamped again and pass on to the loading system.

One of the plant's many sidings is located alongside the cutting shop and the billets are loaded into the cars by means of an ingenious gravity carrier system, it being possible to load three cars simultaneously. The engraving shows this system to advantage, the tables in the foreground serving as a place to store billets while cars are being shunted. The billets, when going to the tables are carried on a continuation of the carrier from the dull-dozer, but when being loaded into cars are carried up the elevator to the distributing center where they are guided into the proper conveyor by the man stationed at this point. A removable extension of the conveyors carries the billets into the cars where they are piled for shipment.

An extremely high rate of production is maintained in this department, a rate of 10,000 per day being easily maintained. This rate is possible through the co-ordination of the working force and by means of the conveyors, which were supplied by the Canadian Matthews Gravity Carrier Co., Toronto.

Welfare

The present trend towards better working conditions, protection from industrial accidents, and a humanitarian interest in the employees' general welfare, is well illustrated in the plant under consideration.

Much can be done in the prevention of accidents by proper guarding of points of possible danger and by the provision of warning signs where necessary. One especially commendable feature in the operation of this plant is seen in the explicit instructions for starting and controlling the apparatus of the plant.

These instructions are in most cases painted in large letters on a prominent part of the motor-starting gear and leave nothing to the operator's experience and memory.

All accidents can never be eliminated and where such occur they are taken care of in the company's own hospital with its staff. A bright and airy ward is provided for the more serious cases, and a well-equipped operating room anu diet kitchen form part of the hospital.

Meals are served at cost to the men and staff, and while conforming to the many food regulations at present in force these meals are both sufficient in quality and quantity to meet the demands of those engaged in strenuous labor.

The men's dining room seats 200, and the men may either sit down at a hot dinner of meat or fish with coffee, tea or milk, vegetables and dessert, or if desired may purchase at cost sandwiches and other food for consumption elsewhere. Tobacco is also sold.

The staff dining room is housed in a separate building adjacent to the general offices and in the two dining rooms accommodation is provided for about fifty meals at a time. A well appointed kitchen is provided and the meals here are also served at cost.

A fire brigade formed of certain of the men employed in the plant forms a very necessary feature for the operation of the fire fighting apparatus with which the plant is equipped.

TOOL STEELS

By L. V. R.

The enormous increase in the output of munitions has involved so large a demand for special tool steels that a concise statement of the most efficient heat treatment provides an acceptable contribution to the literature of the subject, and should be of great value to both tool makers and users. The special properties of these steels demand thermal treatment totally different from that of ordinary carbon steel, and many toolmakers have been long in realizing this, and thus obtaining the best value of the expensive constituents which impart the essential properties. In order to appreciate more fully the causes of hardness in these special tool steels—by which term is understood those steels, in which elements other than carbon have been added to impart the desirable properties—the cause of hardening and the effect of tempering on carbon steels are first outlined. In the annealed state carbon in steel exists as a definite carbide below 700 deg. C. As the temperature is raised beyond this point the independent crystals of carbide cease to exist, and the carbide is in a state of solution in the iron. It is in this condition that it imparts hardness. Quenched from this temperature the carbide is forcibly retained in this solution form which causes the hardening. A carbon steel thus hardened to its maximum degree, however, possesses a very low elastic limit, and is consequently quite brittle.

This initial brittleness is removed by tempering, which relieves the internal stresses set up in quenching. The softening caused by tempering is due to some of the carbide of iron retained in solution by quenching being again dedeposited. The amount is readily con-

AFTER THE GOTHIC BARS ARE NICKED BY THE OXY-ACETYLENE TORCH THEY ARE CONVEYED TO THE BULLDOZER SHOWN AND BROKEN INTO BILLETS OF THE PROPER LENGTH.

trolled by the temperature of tempering, so that any combination of properties between the extremely hard and brittle and the relatively soft annealed state can be obtained.

With carbon steels it is only possible to harden completely if the mass of the steel is small. Remarkable differences in properties are produced by comparatively slight differences in the rate of cooling.

With special steel however, this equivalent of quick cooling is obtained by the addition of elements such as nickel, manganese, tungsten and chromium. These lower the normal temperature of the carbide charge, the variation of temperature being such that it can be brought down to ordinary temperatures. Thus, in these steels, the properties are modified from within, and therefore practically the same quenching effects are obtained through the whole mass. The effect of rate of cooling is well illustrated in the case of chromium steel. Thus in a steel containing over 6 per cent. chromium and 63 per cent. carbon, it was found that with two lin. cube specimens, heated to 1,000 deg, C., one cooled on an asbestos pad in still air, and taking about half an hour to reach normal temperature, gave a Brinell hardness number of 642; while the second cooled slowly in the furnace over a period of one hour, gave a hardness value of only 281 on the same scale.

Importance of Temperature

With tungsten steels the hardening temperature is of the utmost importance. Broadly speaking, this should be practically as high as possible, short of actually melting the metal. Thus if air-hardened from 1,050 deg. C., the steel loses its hardness more quickly than if hardened from, say, 1,250 deg. C., and, further, it does not show anything like the same degree of secondary hardening. The reason for this is that the tungsten present does not go completely into solution until a temperature of the order of 1,250 deg. C., is reached. Further, the hardness thus acquired is retained through reheating up to 500 deg. C., but in addition, by increasing the secondary heating to 600 deg. C., a marked increase in the hardness takes place, and reaches a value in excess of that obtained when first hardened.

Finally, the addition of chromium to the composition usual for high speed cutting steel—for example, 18 per cent. tungston, 6 per cent. chromium, and 63 per cent. carbon—induces considerable hardness in the air hardened state, but this markedly falls off as reheating to 500 deg. C., takes place, while at 600 deg. C., a substantial secondary hardening takes place which makes the material much harder than initially air-hardened. These facts are of great importance, and indicate the desirable heat-treatment of tools before putting into use. This essential secondary hardness can be effected by either (1) air hardening and reheating to the necessary temperatures, or (2) quenching from the hardening temperature in a suitable bath of molten lead or suitable liquid which is kept at the correct temperature. The suggestion of some workers that this secondary treatment is not necesary in order to obtain the best cutting speeds, and that the same effects can be obtained by using the air-hardened tool and slowly increasing the cutting speed to the maximum, is, in a limited sense, true, the frictional heat of the work done subjecting the tool to the secondary temperature; but this treatment involves undue wear of the tool, as it passes through a relatively soft condition.

GRAVITY CARRIER USED IN DISTRIBUTING BILLETS TO FREIGHT CARS.

WORKS ACCIDENTS, THEIR CAUSES AND REMEDIES

By M. A. R.

An investibation of the factors concerned in the causation of industrial accidents has recently been conducted by Dr. H. H. Vernon on behalf of the Health of Munition Workers' Committee, and the results are now available. Data relating to upwards of 30,000 accidents were collected at four factories during periods ranging from nine months to over forty years. Some interesting conclusions are drawn and various suggestions are made for lessening the risks to which factory workers are exposed.

While speed of production is an extremely important factor, Dr. Vernon says that accidents are very largely due to carelessness and inattention, and could be diminished by preventing the workers from talking to one another. At all the factories the night shift workers suffered fewer accidents than those on the day shift. This was due, not to the smaller output but the calmer mental state of the night workers.

These workers have for the most part forgotten the excitement and pleasures indulged in shortly before coming on to night shift, and they have nothing but an unexhilarating breakfast and bed to look forward to. Such a mental state is impossible of achievement by the day shift workers, but something in the way of mental calm and equilibrium can be attained by stopping all conversation excepting that relating to the work in hand. If the workers would consent it would be a good plant to induce temporary deafness by plugging the ears and so shut out the noise of the machinery, which is in itself an important cause of distraction and fatigue. Again, if it were practical it would be of value to shut out the sight of surrounding objects by separating the lathes or other machines from one another by partitions.

Hours Influence Fatigue

It is pointed out that the production of excessive fatigue, with its accompanying increase of accidents, can be almost entirely avoided by choosing suitable hours of labor. It can also be combated by the introduction of seats for the standing workers to rest on occasionally when they are not actually working, and of the most suitable seats possible for sedentary workers. The influence of fatigue on accidents to women was strikingly shown at a fuse factory, when the operatives were working a twelve-hour day, or seventy-five hours a week. The women's accidents were 2½ times more numerous than in the subsequent ten-hour day period, but the men's accidents showed no difference. Also the women were treated for faintness nine times more frequently than the men, and were given sal-volatile twenty-three times more frequently, whereas in the subsequent ten-hour day period they were treated for faintness and given sal-volatile only three times more frequently.

It was found that women suffered twice as frequently as the men from sprains, and were especially liable to wrist sprains at the fuse factory, as they had not sufficient strength to push home the clamping lever of the lathes. The women at the shell factories suffered nearly four times more burns that the men, chiefly from hot metal turnings. Hence the sprains could be reduced by alterations of machinery and the burns by protecting the hands.

Heat Treatment and the Hardening and Tempering of Steel

By Prof. C. A. Edwards, D.Sc.
Metallurgical Dept. Manchester University

Heat treating of steel must depend to a large extent upon its carbon content and upon its other constituents. The author, in a paper read before the Manchester Association of Engineers, gives interesting facts relative to heat treating in general, both carbon and alloy steels being dealt with.

THE very wide variety of steels which are used in the industries of the present day are somewhat arbitrarily classified into two groups. These are the carbon steels and the so-called special steels.

As regards carbon steels, the chief elements other than iron, which are almost invariably present in this class are carbon, manganese, silicon, sulphur and phosphorus. Phosphorus and sulphur may definitely be regarded as impurities; phosphorus renders the metal "cold-short," whilst sulphur makes it "hot-short" or brittle when at a forging temperature. The presence of small quantities of silicon in carbon steel is often a distinct advantage, especially when considering the casting properties of the metal. With the correct amount of silicon present, the formation of blow holes can be prevented, and the contraction which takes place during solidification can be reduced to a minimum, which means less trouble as regards "piping" and "drawing."

In all carbon steels the presence of a certain amount of manganese is essential. The action of this element is twofold: (1) It reduces any oxide of iron which may have formed in the steel during the final stages of its manufacture, and since the influence of very small percentages of oxide of iron is so highly deleterious as to make it almost impossible to forge the material, the first action of manganese is that of a cleanser of the liquid metal. (2) An excess of manganese over that required to deoxidise the metal is necessary to combine with the sulphur present, and thus convert that element, from the objectionable compound sulphide of iron into the

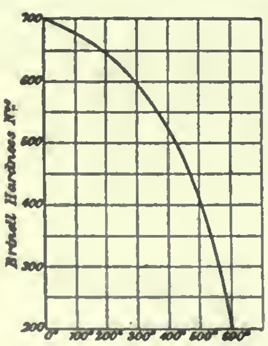


FIG. I—TEMPERING TEMPERATURE.

relatively inert compound sulphide of manganese.

Carbon.—This is the most important constituent of all steels. As regards annealed carbon steels, the influence of carbon is more or less progressively to raise the ultimate stress from, say, 18 ton per square inch when no carbon is present, up to something of the order of 40 tons with 0.90 per cent. of carbon. A still greater variation in the proportion of these steels can be brought about by subjecting them to different heat treat-

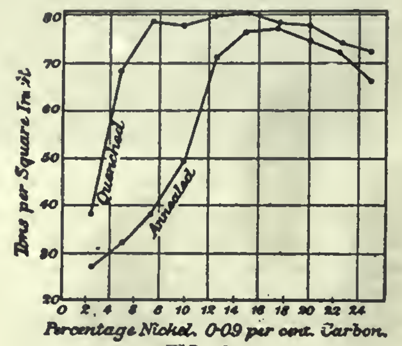

FIG. 3

ment. Briefly, heat treatment may be stated to consist (1) of hardening the metal by quenching from a temperature which depends upon the carbon content, and (2) tempering the hardened material by heating to certain low temperatures which are selected in accordance with the particular properties it is desired to obtain. It may here be useful to note, that providing the quenching is properly conducted, the degree of hardness that is attained increases more or less proportionately as the carbon percentage is raised to 0.90.

It is quite unnecessary, even if there were time and space at the author's disposal, to attempt to give a detailed description of the facts relating to the cause of the hardening that is produced as a result of this simple quenching treatment; and still less is it desirable to give

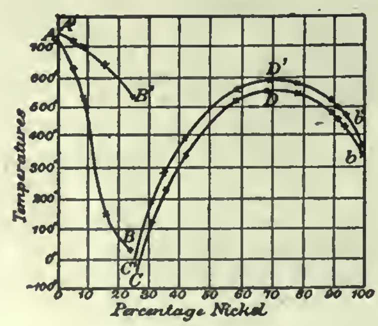

FIG. 2.

an account of the many conflicting theories which have been advanced to explain why the hardness is thus increased. Nevertheless, it will be advantageous briefly to draw attention to one or two of the more salient features in this connection, because they will make it more easy to appreciate the peculiar properties of special steels.

In the completely annealed or soft state the carbon exists as carbide or iron,

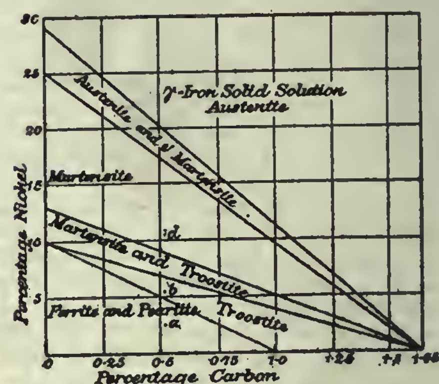

FIG. 4—NICKLE STEELS.

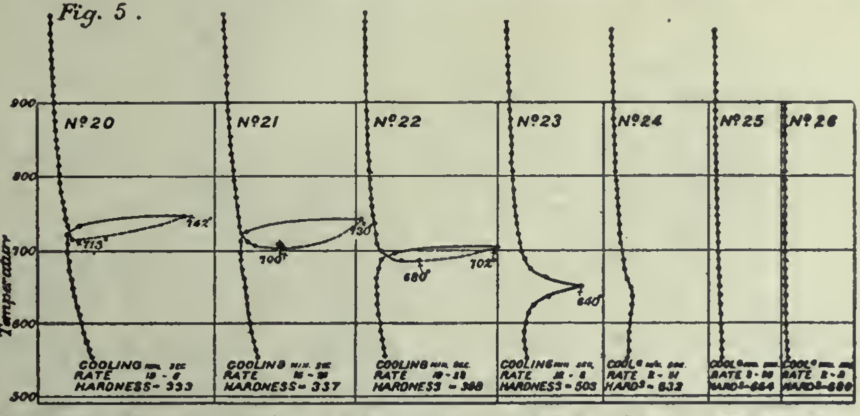
Fe_3C, distributed throughout the mass of iron. When this mixture is heated no physical change occurs until a temperature of 700 deg. C. is reached. At that temperature, however, what were previously independent crystals of the compound Fe_3C, and iron, cease to exist, the carbide is dissolved by the iron. This change is accompanied by an evolution of heat.

The action of the above constituent in steel, when heated to 700 deg. C, is in many respects similar to that of the two solids, ice and salt, when they are brought into contact at a temperature above minus 21 deg. C. The only difference being that in the latter instance the solution which is formed is liquid, whilst in the former it is solid. In both cases the original constituents can be separated from solution by cooling when the latent heat of solution is again given out.

Before carbon steel can be hardened by quenching it must be heated to and quenched from a temperature it which the carbide of iron is in solution. If the quenching is sufficiently rapid it prevents the separation of the carbide and the evolution of heat which accompanies that change, and it is the forcible retention of the carbide in this state which causes the hardening. If a carbon steel such as is used for machine-cutting purposes is hardened to its maximum degree, it would possess a very low elastic limit and would consequently be quite brittle.

The well-known operation of tempering is applied to remove this initial brittleness and the internal stresses which are set up in the quenching treatment. The change of hardness that is brought about by tempering carbon steels at different temperatures is qualitatively illustrated in Fig. 1, page 267; the softening is due to the carbide of iron which was kept in solution, by the sudden cooling from high temperatures, being again deposited. Since the amount



Initial Temperature, 1,200°C. Influence of Initial Temperature on Critical Cooling Velocity.

FIG. 5.

of carbide in solution can be regulated by controlling the temperature of tempering, it will be seen that any combination of properties between the extremely hard and brittle and the relatively soft annealed states can be obtained. The same results can be produced, though the operation is by no means so readily standardized, by quenching the metal in different mediums or by varying the temperature of theh quenching liquids. In both these circumstances the action is to vary the rate of cooling, and this governs the temperature at which the carbide change tends to take place, and also the amount of that transformation which actually occurs.

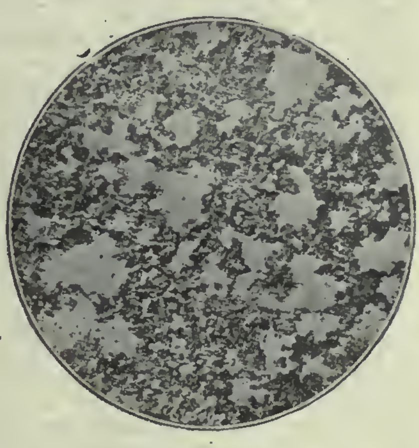
With carbon steels it is only possible completely to harden the metal if the mass of steel is small. In other words these remarkable differences in the properties are produced by comparatively slight differences in the rate at which the mass is cooled from the high temperature. For example, the exceedingly hard state is obtained if the time taken in cooling down from, say, 900 deg. C, is only a few seconds, but the metal is quite soft if the time taken to cool over the same range of temperature is something of the order of 5 minutes. Hence, it is obviously impossible to bring about any material change of hardness or tensile properties throughout the mass of a large carbon steel forging by modifying the rate of cooling. With special steels, however, this difficulty is completely overcome by the introduction of such elements as nickel, manganese, tungsten, chromium, etc, which may be regarded as producing the same effect as is attained by quenching ordinary carbon steels.

Broadly speaking, the above and other elements lower the normal temperature of the carbide change, and thus influence the general mechanical properties of the mass in a manner similar to that of rapidly-cooling carbon steels. By varying the percentage of these special constituents the temperature of the carbide change can be lowered to any degree down to the atmospheric temperature, and, in consequence of this, steels with almost any desired combination of properties can be readily obtained. There is one great advantage in the use of these special steels, namely, their properties are modified from within, and therefore, practically the same quenching effects are obtained through the whole mass.

In a lecture of this kind it would be impossible to give anything like a complete description of the properties of all the special steels which are in use, but it is hoped that, by taking a few typical examples of some of the more interesting cases, members will be able to form a fairly good idea of the action of the special elements which are used in modern steel metallurgy.

Nickel Steels.—The influence of nickel upon the thermal critical points of iron is shown diagrammatically in Fig. 2. The line AB shows the position of the critical points as they occur when the specimens are slowly cooled from moderately high temperatures. This curve, which also depicts the transformation from the non-magnetic into the magnetic state, indicates that with about 25 per cent. of nickel the change does not take place until the atmosphere temperature is reached. Therefore, with 25 per cent. of nickel and a very small percentage of carbon, the steel is non-magnetic at 0 deg. C. If, however, such a sample is cooled to below 0 deg. C. the magnetic transformation is effected, and these properties are retained even when the temperature is subsequently raised to above 500 deg. C. The corresponding changes with lower percentages of nickel and a rising temperature are illustrated by the line A′ B′.

It follows from what has just been said that steels containing from 0 per cent. to 25 per cent. of nickel when at temperatures within the A, B B′, may be either non-magnetic or magnetic according to whether they approached those ranges of temperature by being heated or cooled. This group of steels is, therefore, known as the irreversible series, because the magnetic transformation is



AFTER CURVE 21; COOLING VELOCITY 16 MIN., 28 SEC.; HARDNESS 337.

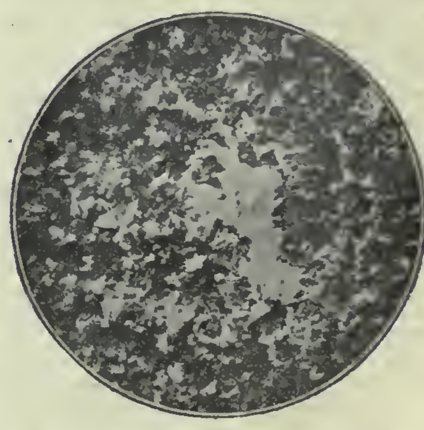


FIG. 7—AFTER CURVE 22.. COOLING VELOCITY 12 MIN., 33 SEC.; HARDNESS 398.

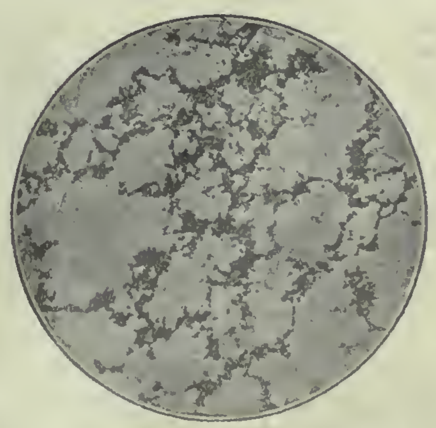

FIG. 8—AFTER CURVE 23; COOLING VELOCITY 12 MIN., 8 SEC.; HARDNESS 503.

AFTER CURVE 25; COOLING VELOCITY 3 MIN., 35 SEC.; HARDNESS 664.

not a reversible reaction as regards constancy of temperature.

Some idea of the effect of nickel upon the tensile strength of iron will be obtained from a glance at Fig. 3.

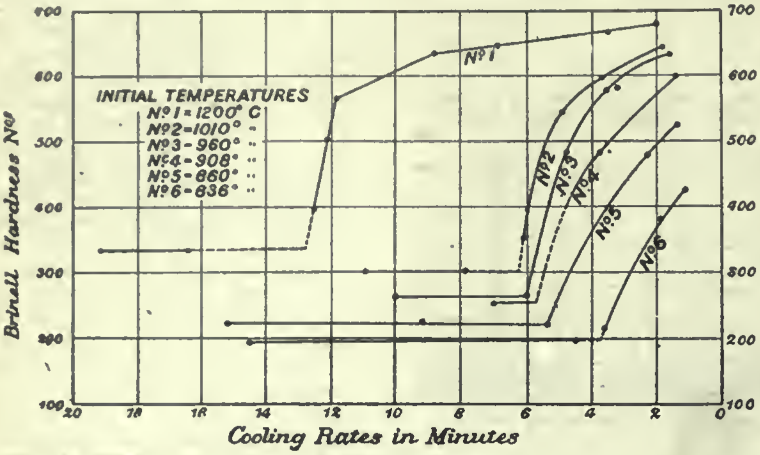

FIG. 10—EFFECT OF INITIAL TEMPERATURE ON CRITICAL COOLING VELOCITIES AND HARDNESS.

In this diagram the lower curve represents the tensile strengths of slowly-cooled specimens, whilst the upper one corresponds with the quenched materials. With the introduction and increase of carbon up to 0.9 per cent. to the nickel-iron alloys, the effect is more rapidly to raise the tensile strength, in other words, the carbon acts in the same direction as an increased percentage of nickel. Thus, for example, with no carbon the maximum ultimate stress is obtained with 15 per cent. of nickel, whilst with 0.9 per cent. of carbon practically the same properties are produced with only 7 per cent. of nickel. One interesting result of this has been indicated by Dr. Guillet, as follows:

From the diagram Fig. 3 it will be observed that a slowly-cooled steel with 7 per cent. of nickel and less than 0.12 per cent. of carbon has a tensile strength of 35 tons to 38 tons per square inch, an elastic limit of 25 tons to 28 tons, and elongation of about 30 per cent. When it is remembered that a steel containing the same amount of nickel along with

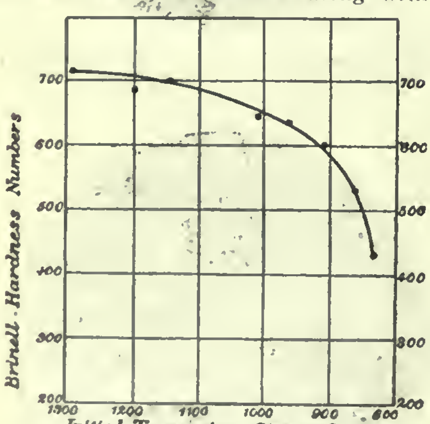

FIG. 11—EFFECT OF INITIAL TEMPERATURE ON HARDNESS WITH AIR COOLING.

0.9 per cent. of carbon, possesses, even after slow cooling, practically the same mechanical properties as a hardened cutting tool, it will be readily recognized that such facts can be advantageously utilized for certain special purposes. Starting with a steel containing 7 per cent. of nickel and 0.10 per cent. of carbon, it is possible by simply carburizing the surface and then allowing the article to cool slowly, to obtain the same results as by carbonizing and quenching an ordinary mild carbon steel. If this is done with the necessary care all the worries which accompany case-hardening by quenching can be avoided.

As a result of investigating a large number of nicked steels, Dr. Guillet has constructed a diagram (Fig. 4) which summarizes the data he got.

Whilst this chart is a very useful one, particularly as regards the effect of varying compositions upon the internal structure of the steels, there are certain defects which need a more complete explanation that he has given. Perhaps the most important point in this connection is that no account is taken of the influence of initial temperature and rate of cooling. The question of time is an extremely important one and, as I hope to show later, it needs very careful consideration. In fact, it is the author's opinion that metallurgists will in the future have to pay far more attention to the quantitative examination of the time factor than they have generally done hitherto. The necessity of studying the influence of time becomes particularly manifest when we come to consider chromium steels.

Chromium Steels.—Until quite recently different investigators held diametrically opopsite views as regards the function of chromium in steel. Some were of the opinion that this element tended to retard the carbide transformation and thus render the steel more or less self-hardening, whilst others maintained that it both raised the temperature of that change and facilitated its completion. Recent work has shown that this diversity of opinion was due to the influence of the time factor not being properly appreciated.

When making experiments with a steel containing a little over 6 per cent. of chromium and 0.63 per cent. of carbon, the author observed the following facts: Specimens, 1 in. cube, were heated to 1,000 deg. C., and then allowed to cool in the following manner—one was taken out of the furnace and allowed to cool on an asbestos pad, in still air, taking about half an hour to reach the ordinary temperature, and the other was more slowly cooled in the furnace, the time taken being about an hour. The former was extremely hard, but the latter was quite soft. The hardness values were:

	Brinell Hardness No.
Cooled in air	642
Cooled in furnace	281

These facts clearly demonstrate that the rate of cooling plays an important role in determining whether the steel becomes what is known as self-hardened or not, and they lead to a thorough investigation of the influence of time and temperature upon the hardness of this and other chromium steels.

For this purpose specimens, 1 in. cube, were heated in a small electrical-resistance furnace and then cooled at varying rates. In order to obtain the necessary variations in the rate of cooling, the samples had to be moved to different positions inside, and in some cases outside the furnace. In all experiments accurate cooling-curve data were taken and hardness determination made.

A typical series of cooling curves are given in Fig. 5, along with the corresponding rates of cooling and hardness values. A few representative microstructures are also given in Figs. 6, 7, 8 and 9. The curves and data in Fig. 5 are particularly instructive, for they give a clear indication of the close connection which exists between the character of the carbide critical point and the hardness of the steel. Comparing the curve No. 20 with No. 21, it will be noticed that the increased cooling rate has lowered the temperature at which the carbide change commenced, but in spite of this, when the transformation once began, the evolution of heat was so great as to cause the temperature of the mass to be raised from 700 deg. up to 730 deg. C. In curve No. 22 the change did not begin until 680 deg. C., and the heat that was then developed was not sufficient to give such a high rise of temperature as in curve No. 21. With curve No. 23, which was only 25 seconds quicker than the previous one, the character of the point is quite different; there is no real rise of temperature, but merely a retardation in the rate of cooling, and it will be observed that this comparatively slight acceleration in the cooling rate has produced a material increase in the hardness of the steel. With still quicker rates, the carbide change can be completely suppressed, and when this is accomplished the maximum hardness is attained. The structures in Figs. 6, 7, 8 and 9 confirm this, the dark areas represent those in which the carbide has fallen out of solution whilst the light areas correspond to an extremely hard constituent wherein the carbon has been retained in solution.

Similar results got with the same steel when cooled from different initial temperatures are plotted in Fig. 10, page 268. Here it will be seen that as the initial temperature is raised the rate of cooling may be decreased to a considerable extent and hardening of the metal is still brought about. In other words, the critical rates of cooling which are represented by breaks in the respective curves become longer as the initial temperature is raised. It should be noted that the rates that are plotted in this diagram are strictly comparable, that is to say, they are times taken to cool the

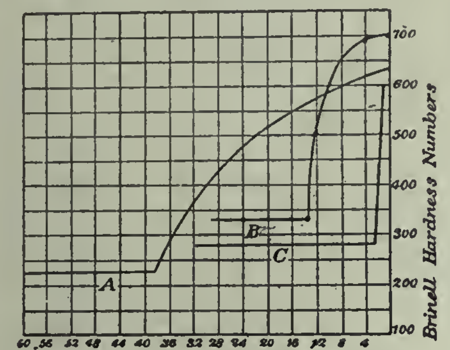

FIG. 13—COOLING RATE IN MINUTES.

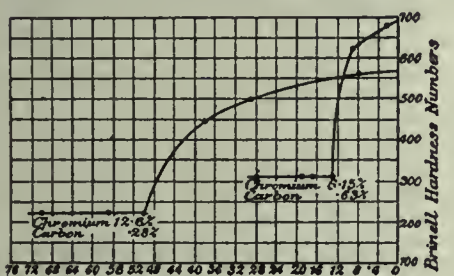

FIG. 12—COOLING RATE IN MINUTES.

specimens over a given range of temperature which was the same for all experiments. The hardnesses that were obtained for this steel when cooled in the air from varying initial temperatures are plotted in Fig. 11, page 268.

The critical cooling rates at which hardening of the steel becomes evident that have been referred to above ar not only influenced by the temperature from which the cooling commences, but also by the carbon and chromium content of the metal. To illustrate this it is only necessary to compare the results that have been got for three other samples, with those that have already been described.

If we first consider a steel containing 12.6 per cent. of chromium and 0.28 per cent. of carbon, after cooling at various speeds from 1,200 deg. C., we find that its hardening characteristics are widely different from those of a steel with 6.0 per cent. chromium and 0.63 per cent. carbon. The hardness-rate data for the two specimens are plotted side by side in Fig. 12. The hardness of the two samples in the annealed state—represented by the horizontal branches of the two curves—are substantially different, and there is a similar difference between the maximum hardness obtained by quick cooling. Perhaps the most interesting feature is that with 6 per cent. of chromium, the cooling rate at which hardening appears is 12.5 minutes, whilst the corresponding rate for the steel containing 12.6 per cent. of chromium is 50 minutes. An even better conception of the effect of composition in this connection will be gained by an examination of the curves in Fig. 13, which relate to steels having the following compositions:

	Chromium.	Carbon.
A	6.18	0.37
B	6.15	0.63
C	6.16	0.97

In this series the chromium is practically the same in each case, whilst the carbon varies from 0.37 per cent. to 0.97 per cent. It will be seen from the respective curves in Fig. 13, that sample A was more readily hardened than B, but that B was more easily hardened than C. This statement is not intended to apply to the degree of hardness which can be attained, but purely to the critical cooling rate. These facts lead us to rather a novel idea from a metallurgical standpoint, for it would appear that by starting with a steel containing 6 per cent. of chromium and 1 per cent. of carbon, if the carbon content could be reduced in any given part of an article to something below 0.60 per cent., it would then only be necessary carefully to adjust the rate of cooling to get those parts with the low percentage of carbon intensely hard whilst the other portions would remain relatively quite soft. In other words, by a process of decarburizing any required surface it should be possible to produce the well-known case-hardening effects which are now produced by carburizing other steels.

Some rather crude laboratory experiments have been made in this direction, and the results have shown that case-hardening can be accomplished in this way. Whether this is likely to prove to be of any real practical value or not the author is at present unable to say, but it would be well worth making further experiments with that in view. It might be possible to control the process as easily as the carburizing of the nickel steel already cited, and if that is found to be the case, in ordinary times the chromium steel should be considerably cheaper.

Tempering of Chromium Steel

For discussing the influence of chromium upon the tempering properties, attention will be confined to one example which has been selected on account of its indirect bearing on the question of high-speed cutting tools. Results are plotted in Fig. 14, which illustrate the effect on the hardness of tempering a hardened steel, containing 6 per cent. of chromium and 0.63 per cent. of carbon, at progressively increasing temperatures. These results may be summarised as follows: As the temperature is raised to a little above 300 deg. C., the Brinell hardness falls from above 700 to well below 600. After heating between 300 deg. and 500 deg. C. the hardness becomes a little higher than it was after treating at 300 deg. C. With temperatures above 500 deg. C. there is a rapid fall in the Brinell hardness. It should be noted that the percentages of chromium and carbon in this steel are the same as are usually present in a high-speed cutting tool; there is, however, no tungsten present, and without that element such a steel cannot be used for cutting at high speeds.

Tempering of Tungsten Steel

The effect of heating a hardened steel containing 0.63 per cent. of carbon and 19.28 per cent. of tungsten is shown diagrammatically in Fig. 15. With the exception of the absence of chromium this material is typical of a high-speed steel. In this instance it will be observed that the Brinel hardness of the steel after hardening in an air blast from about 1,300 deg. C., is only 500, but that this value does not fall after the material has been heated to temperatures up to 500 deg. C. Further, by increasing the secondary heating to a little over 600 deg. C. a marked increase in the hardness takes place, and reaches a value

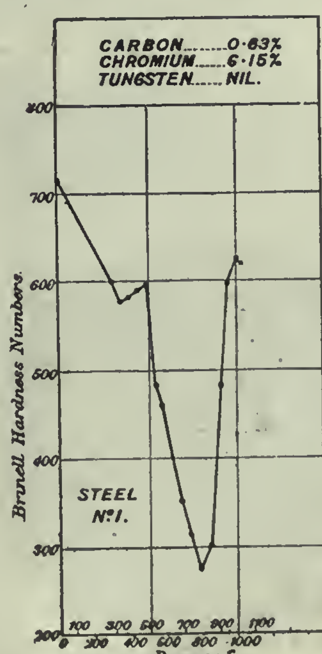

FIG. 14.

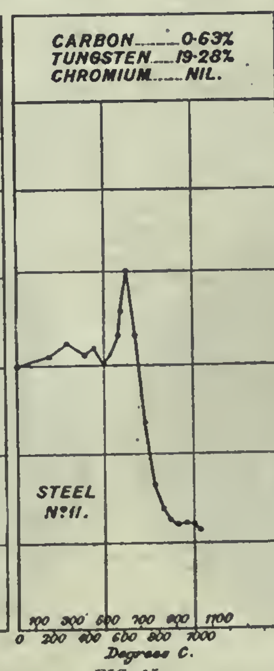

FIG. 15.

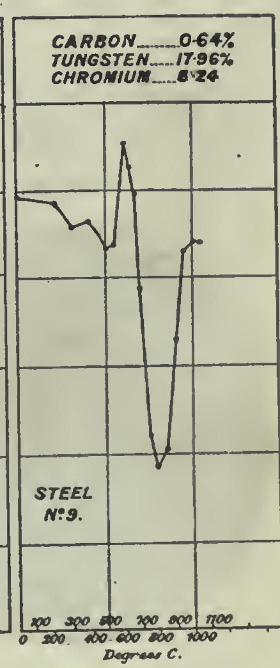

FIG. 16.

which is greater than it was when first hardened.

Tempering of Chromium Tungsten and High-Speed Cutting Steel

With steel containing 18 per cent. of tungsten, 6 per cent. of chromium and 0.63 per cent. of carbon, the effect of reheating properly hardened samples is shown in Fig. 16. Here it will be seen that the steel is very hard in the air-hardened state, and that the hardness falls rather markedly as the reheating is raised to 500 deg., but at 600 deg. C. a substantial secondary hardening sets in which makes the material much harder than it was in the initially air-hardened state.

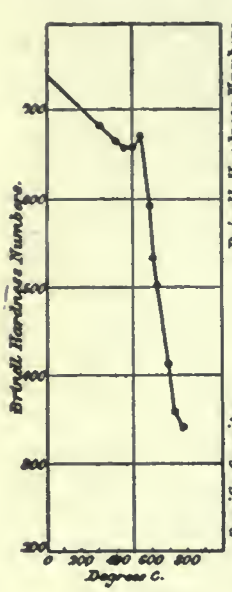

FIG. 18.

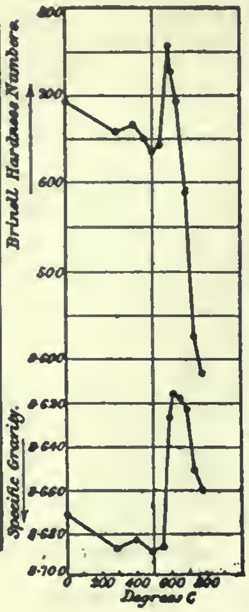

FIG. 17.

These facts are of considerable importance from the point of view of the machine shop, for they mean that high-speed tools should be treated in such a way that they possess this secondary hardness before they are put into use. This can be effected in one of two ways: (1) The tool may be air-hardened in the usual manner and then reheated to the necessary temperature, or (2) the same results can be obtained by hardening the tool by quenching, from the hardening temperature, in a bath of molten lead or suitable liquid which is kept at the correct temperature.

It has been suggested by some workers that this secondary treatment is not necessary in order to get the best cutting speeds out of a tool, and that the same results can be obtained by using the tool in the airhardened state and slowly increasing the cutting speed to the maximum. It is quite true that if this is done the frictional heat of the work done will indirectly subject the tool to the secondary heating, but in so doing it must be remembered that the tool becomes unduly worn as a result of its having unnecessarily to pass through a relatively soft condition.

Hardening Temperature

The temperature from which high-speed steels are hardened is perhaps the most important in the treatment of this class of steel. Broadly speaking, this should be practically as high as possible short of actually melting the metal. This is very clearly demonstrated in Fig. 17, which represents the influence of reheating samples of the same high-speed steel referred to above, that have been air-heated from 1.050 deg. C. In this instance it will be noted that the steel loses its hardness more quickly than if it had been hardened from, say, 1,250 deg. C., and further it does not show anything like the same degree of secondary hardening.

The difference in this respect is due entirely to the fact that the tungsten present in these steels does not completely go into solution until temperatures approaching 1,250 deg. C. are attained; and since it is to this element when in solution that we owe the property of secondary hardening and the power of retaining hardness at high temperatures, little or no return is obtained from that costly element unless the tool is heated to a high temperature prior to hardening. It should be stated that care must be taken not to heat the steel to such an extent that a partial melting occurs, for this leads to an embrittling of the tool.

Experiments have been made to determine the variations in the specific gravity of high-speed steel after being air-hardened and tempered at different temperatures. A series of these results are plotted in Fig. 18, along with the hardnesses. A change in the hardness is apparently always accompanied with a corresponding alteration in the volume. Thus, with each increase of hardness there is an increase of volume.

Photomicrograph No. 19 is typical of the structure of all chromium-tungsten cutting steels when in the annealed condition; No. 29 represents the normal structure of a properly hardened sample; whilst No. 21 shows what occurs if the steel is overheated, that is, partly melted in the hardening operation. The white irregular-shaped areas or constituent at the crystal boundaries in No. 21 are ex-exceedingly brittle, and impart very inferior cutting properties to a tool.

CONSERVE OR PERISH

Whether we have a high tariff or no tariff, an income tax or a head tax, direct or indirect taxation, bimetalism or a single standard, national banks or state banks, are matters which concern, to be sure, the temporary convenience of the members of society, but their prejudicial adjustment is easily remediable; when ill effects become apparent, the inconveniences may be removed with but little harm to the community and none to mankind at large, or to the future. But whether fertile lands are turned into deserts, forests into waste places, brooks into torrents, rivers changed from means of power and intercourse into means of destruction and desolation—these are questions which concern the material existence itself of society, and since such changes become often irreversible, the damage irremiable, and at the same time the extent of available resources becomes smaller in proportion to population, their consideration is finally much more important than those other questions of the day... Only those nations who develop their national resources economically, and avoid the waste of that which they produce, can maintain their power or even secure the continuance of their separate existence.

IRELAND has a number of ancient water power developments. Some of the corn mills have been uninterruptedly operated by water power since the seventh century, one of which is known as St. Fechin's in County Westmeath. Mills driven by water power were known in the fifth century.

British Government Calls for Increased Production of Shrapnel

By A. G. WEBSTER
Associate Editor Canadian Machinery

THE new 18 pounder shrapnel Mark XII. shell which is now being manufactured in Canada differs from Mark IX in one or two particulars but is essentially the same shell. The Mark XII. shell is .615 in. shorter than the older type; the walls are a shade thicker but the base is the same. The high outside diameter of the body is 3.290 in. and the low 3.280 in., whereas the Mark IX. shell was H 3.29 in. and L 3.27 ins. The powder cup is deeper and smaller in diameter, as also the diaphragm. These variations do not necessarily involve any great change in the method of production although the firm at which the methods are employed as described below, has introduced a number of new features as a result of the experience gained in making the preceding types of shrapnel. New devices have been developed and adopted for certain operations, with the result that production per machine has been increased with a corresponding gain in effeciency. In view of the fact that more shrapnel contracts are being placed in Canada, the method of manufacture as described below will not be without interest.

Cut Off Open End

The first operation is to cut off the open end, which is done on regular cutting-off machines built by John H. Hall & Son, Brantford. The shell is held in the machine by a universal chuck and the correct position obtained by means of a rod gauge carried in a bracket on the bed. When the shell is placed in the chuck, the rod is pushed down the bore as far as it will go and the shell pulled out until the rod bottoms in the shell. The shell is then tightened up in the chuck, the rod gauge withdrawn and cut started. There are two parting tools, back and front, both working simultaneously and operated by the same feed screw in the cross slide.

Rough Facing Base

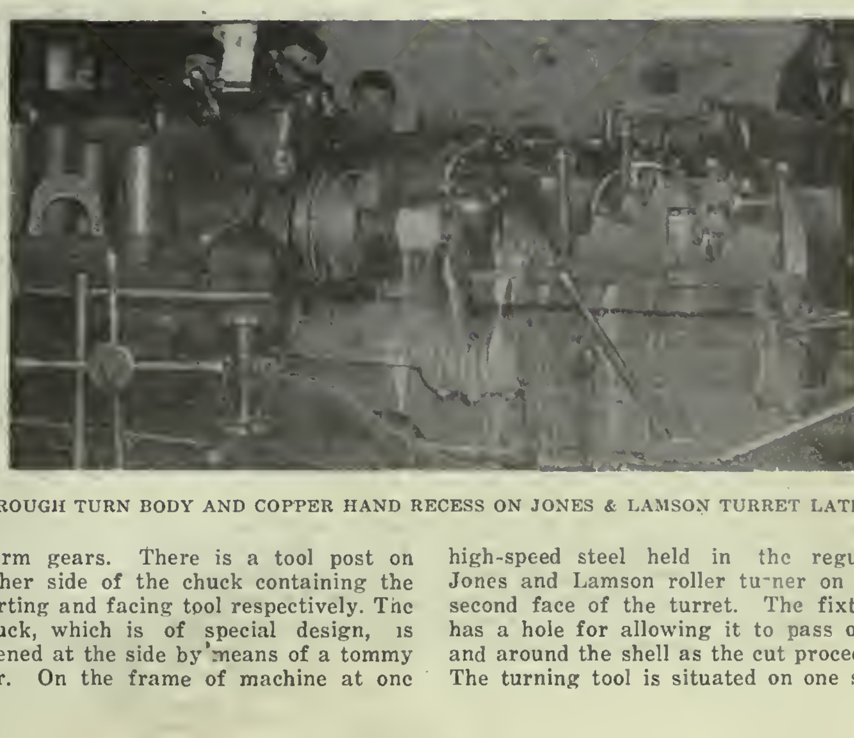
The second operation, rough facing the base, is done on a Hall cutting-off machine and also a special machine built by the Hamilton Gear & Machine Co., Toronto. The Hall machine has one facing tool on front of cross slide. There is a rod in the head for fixing the position of the shell. One roughing cut is taken across the base to remove superfluous metal preparatory to the next operation.

The standard Hall tool blocks were changed so that the high-speed steel tool may be cut off the bar without forging, the tool being set at a slant of 16 degrees, the same as an Armstrong tool holder. This construction saves all forging and about half the grinding of a standard tool.

The Hamilton Gear & Machine Co.'s cutting-off machine is used for cutting off the open end and base at one operation. The machine is belt-driven through gears from the main spindle, the tool slides being driven through worm gears. There is a tool post on either side of the chuck containing the parting and facing tool respectively. The chuck, which is of special design, is opened at the side by means of a tommy bar. On the frame of machine at one side is a bar held in a bracket for locating the shell in the correct position.

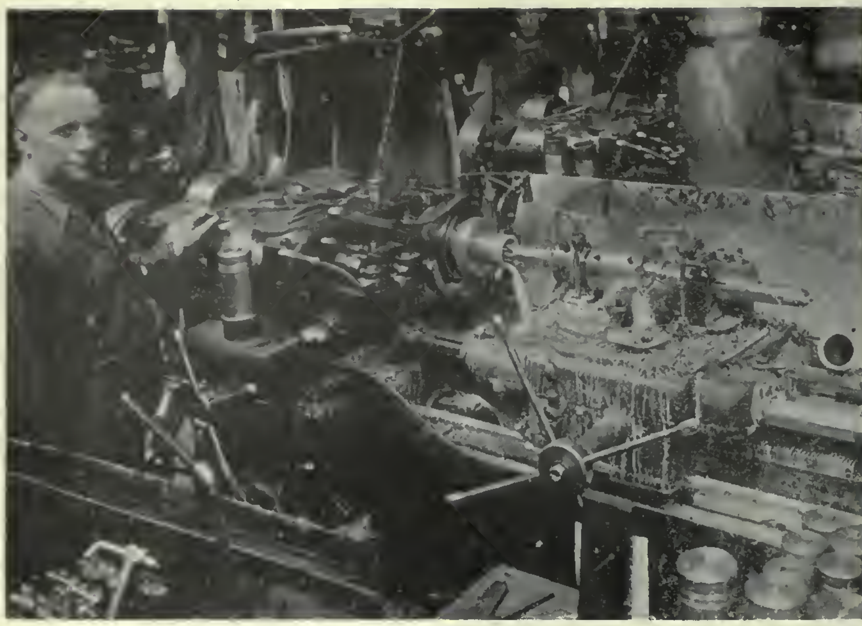
Rough Turn Body

At the third operation the body is rough turned, copper band recess rough formed and base faced. Hartness flat turret, double spindle lathes which are used exclusively for this work were built by the Jones & Lamson Machine Co., Springfield, Vt. This type of lathe is well known but the tooling fixtures were specially designed for this particular service. The turret which is square has three sets of tool fixtures, each set is in duplicate as the lathe has two spindles and two shells are thus machined at a time. The tools on the first turret face chamber the base diameter to help the tools when beginning the cut for rough turning. The shell body is rough turned for a distance of about 7⅝ ins. from the base. The tool used is ½ in. by 1 in high-speed steel held in the regular Jones and Lamson roller turner on the second face of the turret. The fixture has a hole for allowing it to pass over and around the shell as the cut proceeds. The turning tool is situated on one side



ROUGH TURN BODY AND COPPER HAND RECESS ON JONES & LAMSON TURRET LATHE.

of the fixture and there are two rollers on the opposite side. The function of the rollers is to hold the shell up to the tool and at the same time support it. The rollers engage with the shell after it has been machiner and follow immediately behind the turning tool. The turning tool works in a rocker so that it can be moved away from the work by a small lever when the cut is finished and so allow the turret to be drawn back.



ROUGH AND FINISH BORING, NOSE TAPER AND FACING NOSE ON JONES & LAMSON TURRET LATHE.

The third set of tooling fixtures was developed by the company for facing the base, forming the base radius and rough machining the copper band recess. The tool ladder is L shaped and has three tools. One tool set in a forward position faces the base. The next tool at the root of the L then forms a small radius and the third tool roughs the recess. This fixture has also two rollers set opposite to the tools for supporting the shell.

The shells are held in universal scroll chucks with floating scroll so that the pawls do not govern the position of the shell. The shell is mounted on a mandril fitted to the interior of the lathe spindle and is centered by two conical collars sliding on the mandril and driven into the tapering bore of shell by coil springs which are compressed by one action of shoving the forging on the mandril. This latter is accomplished by moving the turret forwards towards the head.

Forming Base Radius

The fourth operation is a short one and consists of finishing the base radius. An engine lathe which is used for this operation has a special fixture attached to the cross slide. This fixture has a forming tool on one side and a roller on the opposite side to steady the shell. When the shell has been chucked, the lathe carriage is brought up to the work. A bar on the fixture, operated by hand, feeds the tool forward by means of a rack and pinion and forms the radius.

Powder Cup Pocket and Diaphragm Seat

At the next operation the fifth, the shell is faced to length, the open and tapered, the powder cup pocket, diaphragm seat and the part of body just above the seat are machined. This operation is done in a Jones & Lamson flat turret, single spindle lathes, the shell being held in an automatic chuck specially designed for this purpose. The turret has four sets of tools.

The first tool is a boring bar with a forming cutter at the end for roughing the powder cup seat, diaphragm seat and the part of shell body immediately above the diaphragm seat. The second tool is a boring bar, the same as the first which takes a second cut on the powder cup seat, etc. The bar holder on the turret has a mortice carrying a cutter for facing theh open end. The third tool is a cutter for forming the taper on the open end, while the fourth is a boring bar which is similar to the first and second, finishes the powder cup seat etc. The cutters on the boring bars are in one piece and are the same shape, conforming to the contour of shell at the base, inside. The lubricant is fed through the bars to the tips.

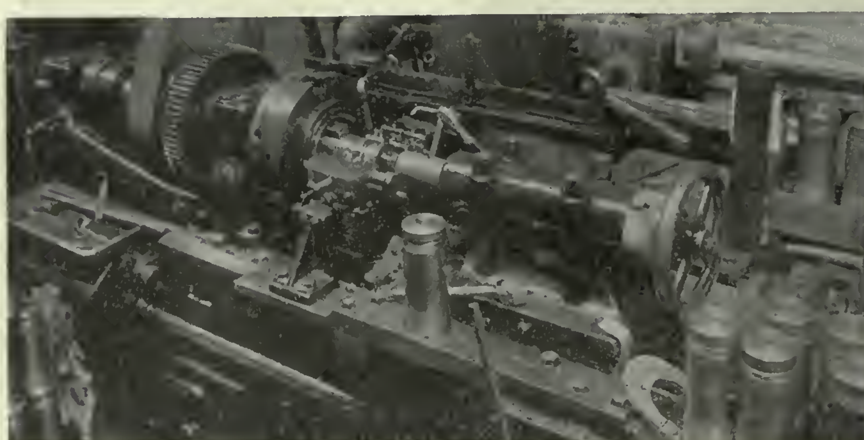
Wave and Undercuts

The sixth operation forming the wave lines and undercuts in the copper band recess is done on heavy duty Le Blond lathes equipped with Bertram attachments. This attachment which is fixed to the lathe bed consists briefly of two fixtures, the front for waving and the back one for undercutting. The waving fixture has a roller which engages with a cam on the chuck face and is pressed against the cam by means of a spring. The cam causes the fixture to oscillate and form the waves. The fixture holding the waving tool is fed in by means of a cam fastened to the lathe carriage, the cam forcing theh tool in when the carriage is traversed.

The fixture at the back carries two undercutting tools, each being fed in at an angle by cams in a similar manner to the waving tool. The waving and undercutting is done simultaneously. The back fixture also carries a guide pin which is swung over to locate the shell in its correct position. The front part of shell is held in a universal chuck and the base is carried in a cup centre on the tailstock. Oil is used in a lubricant.

Heat Treatment and Forging Nose

The heat treating installation at present comprises coal-fired furnaces, but continuous oil-fired furnaces for hardening the shells. This is the seventh operation. The shells are first hardened and then tempered. The shells are heated for 40 minutes in a temperature of about 1,450 degrees Fahr. and then quenched in oil. When a batch of shells have been quenched the oil flows out of the tank by gravity to an underground tank equipped with cold water coils which cool the oil before it is pumped back to the quenching tank. The shells are removed from this tank when practically empty. The oil is circulating almost continually in order to keep it cool. A Bristol recording thermometer is used for noting the temperature of the oil in the tank.



WAVING AND UNDERCUTTING COPPER BAND RECESS WITH BERTRAM ATTACHMENT.

The shells are tempered in a gas furnace for 40 minutes and are then allowed to cool gradually. The degree to which the temperature is drawn is regulated by the resultant schleroscope reading.

The eighth operation, the schleroscope test, now follows. Before being tested the shells are buffed in three places on the body, the band recess is cleaned up and base cleaned up on a grinder. The bore of shell is also cleaned with a wire brush. The shells are then placed on the schleroscope and several readings taken on the scale, the readings ranging from 32 to 35 degrees. At this stage one shell from a series of 500 is selected for the tensile test. The test piece 5 in. long is cut out from the body of shell, from the band recess up towards the nose, machined to the required shape and sent to the government laboratory. The requirements of the test piece are a tensile strength of 48 tons, yield 30 tons and an elongation of 12 per cent.

Lead pots are installed for heating the open end of shells before being closed in. The hydraulic nosing press was built by the Hamilton Gear and Machine Co., and operates at a pressure of 1,500 lbs. per sq. in. Closing in the nose is the ninth operation.

Nose Threads and Profiles

The tenth operation consists of boring and facing the hole in the nose, inside and outside profiles and threading the nose. This operation is done on a Jones & Lamson, flat turret, single spindle lathes equipped with an automatic chuck. There are five sets of tools on the turret. The first set rough bores the holes, faces the nose and roughs the inside profile for a short distance behind the threads. This set of tools consists of two round steel bars one turned over at the end for profiling and the second ground with a square side for rough boring the hole, while the third is square tool for facing the nose. The second tool in the turret consists of a short bar holding a forming cutter for finishing the inside profile. The third tool consists of a bar with a single pointed tool and a facing cutter. The former finishes the bore and the cutter forms the fuse socket seat bevel. The fourth tool is a collapsible tap for threading the nose. The tap was made by the Geometric Tool Co., Newhaven, Conn. The fifth tool consists of a fixture with a cutter for rough forming the outside nose profile. All the stops are set on this machine when it is being tooled up, the stops being located under the turret.

BORING AND THREADING NOSE. FORMING PROFILES AND FACING NOSE ON JONES & LAMSON TURRET LATHE.

Grind Base Diameter

The eleventh operation is grinding the base diameter, that is the part of shell between the band recess and base. This operation is done on an ordinary engine lathe equipped with an automatic chuck. The grinding wheel is on a fixture attached to the lathe carriage and it has an independent drive, and also a fan exhaust for carrying away dust.

Finish Turning Body

Finish turning the body and outside profile is the twelfth operation. This is done on an engine lathe equipped with a forming cam on the carriage. The base of shell is held in a chuck and a threaded centre is screwed into the nose and carried on the tailstock centre. A single pointed turning tool is used, the feed being controlled by the came which is located under the cross slide. A spring keeps the tool box against the cam and also forms the correct profile. The cut starts at the band recess, travels along finishing the body and then the nose profile.

Inspecting and Marking

After the shells have been finish-turned they are washed in a hot solution of soda and water to remove the grease, etc. The preliminary government inspection follows when the shells are carefully examined, gauged and weighed.

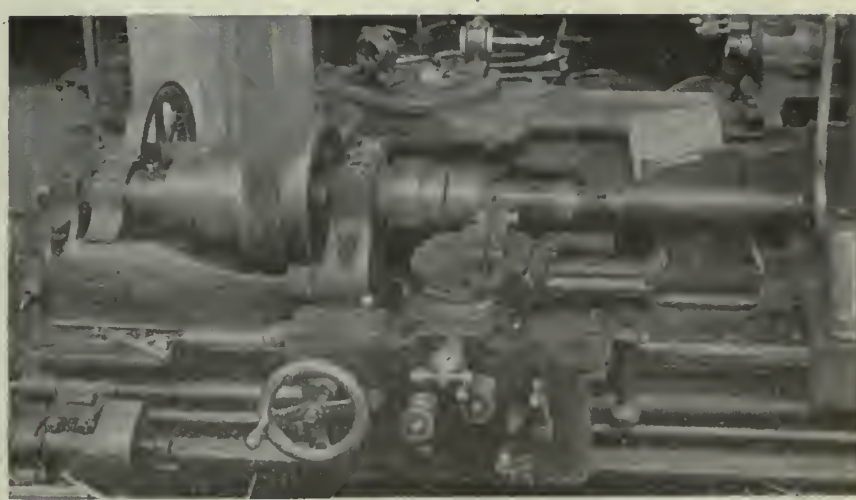
The shells are also arranged according to their series and passed along to the marking machine. This machine, which was built by the Hamilton Gear & Machine Co., is power driven and has a die holder which marks the shell resting in a horizontal position on two rollers. The marks are 18 pdr. XII., initials of the manufacturer, date, and series number. The heat number is marked on the shell body by a similar machine.

Copper Band Press

The copper band press was made by the Hamilton Gear & Machine Co. It has six hydraulic cylinders and operates at a pressure of 1,600 lbs., per sq. in. In the centre of the press there is a plunger operated by a foot lever outside. When the shell is put in the press it is raised up a short distance by means of the foot lever and the pressure applied twice. The shell being given a turn between each squeeze. This applies the pressure to the middle of the band opposite the waves. The foot lever is then released and the shell settles down to the normal position. The pressure is then applied three times, the shell being again given a turn between each squeeze. The pressure is applied on the side of the band completely filling the recess and forcing it into the undercuts.

Copper Band Turning

The copper bands are turned on engine lathe fitted up for this purpose. The base end is held in a chuck while the nose which has the screwed centre is carried on the tailstock centre. A fixture on the lathe bed carries two tools, front and back.



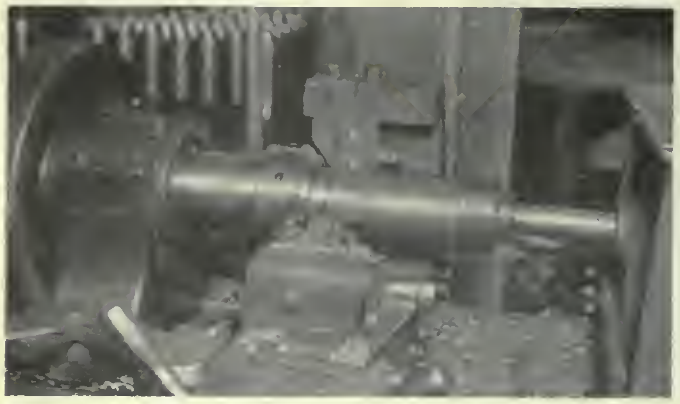
FINISH TURN OPERATION ON SHRAPNEL BODY AND PROFILE.

The tools are mounted vertically, the back tool being inverted. The band is roughed by the back tool while the front tool makes the finishing cut, the operator traversing the tool slide back and forward to marks on the rim of a 9 in.

hand wheel, giving a very fine control over the diameter of the finished band. The fixture also carries a rest for a hand turning tool which removes the burrs.

Assembling and Loading

The shells pass on to the assembling department where the tin powder cup, diaphragm and firing tube are placed in position. The tube is screwed into the diaphragm. The shells are then loaded. A shell is placed under a hopper which measures each charge of bullets. At the bottom of the hopper is a box containing approximately the quantity of bullets required. When the box is pulled out it discharges underneath, the bullets falling through a funnel into the shell. At the same time a slide on top of the box closes the exit from the hopper preventing the bullets from falling down when the shell is being loaded. A stop on the bench locates the shell in the proper position for loading. Each shell holds about 292 bullets, ½ in. diameter, and weighing 41 to the pound. The charge of bullets weighs rather over 7 pounds. The shell is rapped to settle the bullets and then weighed.



TURNING COPPER BAND.

The shells then pass on to be filled with hot resin at 350 degrees. There are two resin boilers, one above the other and heated by gas burners. To prevent any possibility of fire the top boiler has an overflow into the bottom boiler which also has an overflow into a tank under the table and away from the fire. There is a thermometer on the lower boiler. The shells are filled from the lower boiler by a ¼ in. stream of resin up to the middle of the threads in the nose. The shells are then weighed, and weight corrected by bullets or buckshot.

The brass nose socket is first entered in the threads by hand and then screwed in tight on a drill press equipped with a special three-bladed tool, something after the style of a box mill which grips with the blades, digging into the brass socket as the drill spindle is faced down by hand.

The firing tubes are at present being soldered into the brass socket but a new method is being developed for doing this work. The new device is something along the line of a boiler tube expander, which, when turned round in the tube, expands it in the socket. The new type of socket will not have a level at the edge of the hole.

Finishing Socket

The brass socket is finished in a single purpose lathe built by the Hamilton Gear & Machine Co. At this operation the inside face of socket is finished, socket profile turned and recess formed. The fixture on lathe carriage has three tools. The first is a cutter at the front which roughs the socket profile. The second tool in the centre removes the projecting end of firing tube and cleans up the face of socket. When this tool has finished its work the third tool at the back forms the recess. The middle tool holder carries a swinging stop for locating the shell in the correct position. This stop is swung back before the operation begins.

The socket is then cleaned and hand tapped, the ¼ in. grub screw hole hand tapped and powder cup cleaned out with compressed air.

Final Operations

The brass sockets are first inspected and the shells sorted into their proper series. The shells are then weighed; this is the final weighing. The proof shell is taken out, one from each series and the shells then undergo the final inspection.

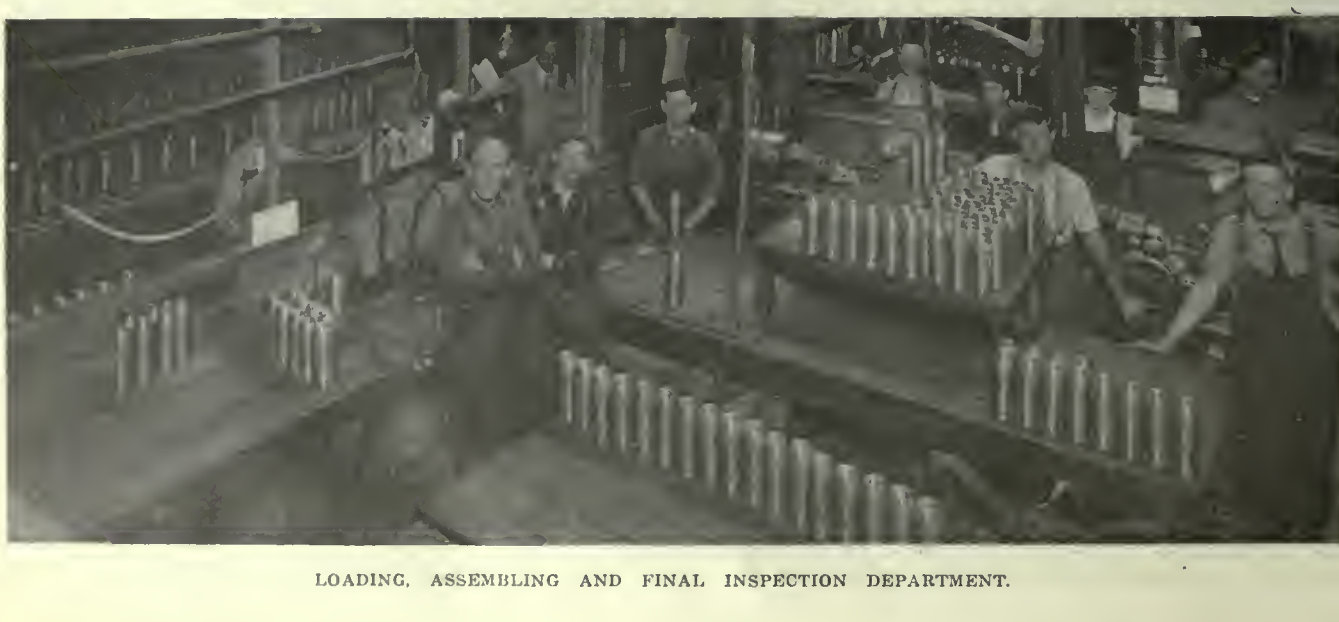
The shells are given two coats of black paint on a machine having six spindles rotated by power. The second coat is put on when the shells are dry, the body being painted lack and the nose red. The shells are afterwards placed on shelves to dry and the paint inspected. A nose plug is screwed into the nose socket and the shells are packed, six in a box.

Weights

The 18 pdr. shrapnel weighs 18 lbs. 8 ozs. with fuse and powder charge and 16 lbs. 10 ozs. 14 drs. without the fuse. At the preliminary inspection before the copper band is pressed on the shell weighs 7 lbs. 10 ozs. 8 drs,

The shell forging comes to the plant with the heat number on the base. This is transferred to the open end after the base is cut off. A symbol is used to represent the heat number throughout the various operations until marking when the original number is substituted for the symbol. The symbol or mark is transferred to the body when the open end is tapered and again to the base in the hardening room. It is transferred finally to the body at the marking operation.

The shells are inspected and gauged after each operation, in addition to the preliminary and final government inspections. An economical method of using tool steel is in vogue at this plant. Pieces of tool steel, too small to be used in the ordinary way are electric arc welded to mild steel shanks. one or more tips to a shank. These welded tips have proved both serviceable and economical.



LOADING, ASSEMBLING AND FINAL INSPECTION DEPARTMENT.

CANADA MACHINERY CORPORATION'S NEW SHOP

THE Canada Machinery Corporation has recently made an important extension to its plant at Galt, Ont., which will enable this progressive concern to extend the scope of its activities and take care of the increasing volume of business. The new building which was erected by P. H. Secord & Sons of Brantford, Ont., will be used as a machine shop, and the machinery that will be installed there will be built in the company's own shops. The new shop will be particularly useful for building the larger types of machine tools as the layout will permit of heavy machinery being installed and ample space for handling big castings. The building is of steel and brick construction and is practically fireproof. The building is 182 feet long and consists of three bays.

The centre bay is 51 feet wide and 36 feet high and covered with a gable roof. As this portion of the building projects above the other bays ample light for the centre of the building is procured by means of lantern windows. These windows, swivelling in the centre and being under control from the floor, give excellent ventilation. A twenty-five ton Niles electric crane, 24 feet above the floor, makes it possible to handle the heaviest castings or machines along the entire length of the building and to load or unload same to or from the G. T. R. switch, which enters the building at the south end.

The second or west bay is 46 feet wide and is lighted by what is practically an all glass wall. The east bay, which is 89 feet wide, is covered by a modern saw tooth type roof, which provides the maximum amount of light and ventilation. The smaller cranes are installed in this bay.

What at once attracts the notice of every practical shop man is the entire absence of steam, water, or heating pipes or electric wiring, all these services being contained in underground distribution ducts. These ducts, into which one may descend by trap doors in the floor, are very large and act primarily to convey heat to the various portions of the building, and are built of solid concrete.

INTERIOR VIEW OF NEW SHOP AT THE CANADA MACHINERY CORPORATION.

The heating apparatus consists of a large steel plate fan with direct connected steam engine, and headers of steam coils installed by Sheldons, Ltd., of Galt. It is situated in the centre of the east bay. This system of heating has the advantage in that while it will rapidly warm up a building, it provides an even distribution of heat as well as a constant change of air.

The matter of daytime lighting having been fully explained in the preceding description it remains only to say that every effort has beben made to have the artificial lighting unexcelled. While the lower portions of the building interior are painted black, the upper portions are white for the purpose of making the building as bright as possible.

CENTER BAY, FROM THE NORTH.

Both of these latter portions of the building have a clear overhead space of 16 feet. The total area of the building is 34,400 sq. ft., unobstructed by interior walls or other obstructions excepting the steel columns.

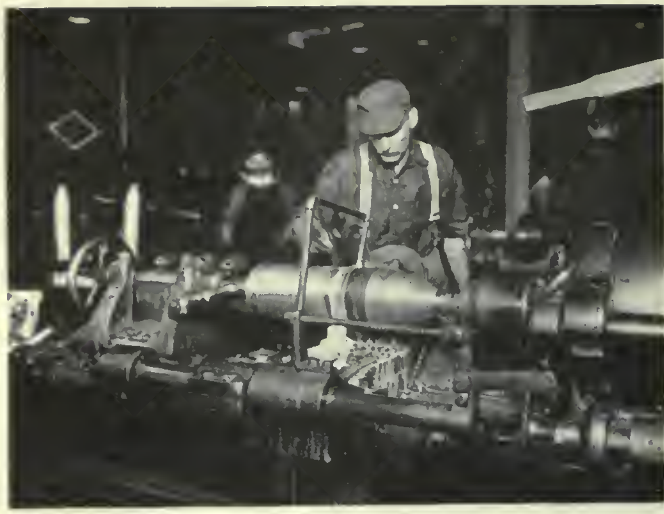
The flooring consists of a thick concrete base overlaid by 2-inch pine planking bedded in pitch, and in turn covered by hardwood matched flooring.

The centre floor is to be used in part for the placing of some of the heaviest tools used in this section of the country, including 10 ft.-16ft. boring mill, large planers, and large horizontal borers, the remainder being utilized to build such large and heavy iron tools as have previously been built by this firm only with difficulty. The west bay will be filled with somewhat lighter machinery, while the east bay will consist of an erecting floor for lighter tools and of a smithing shop, which will be located at the south end. The blacksmith shop is provided with a cement floor.

Electricity generated by steam in the company's present power house and conducted to the various points of service by underground ducts is the form of power to be used, but by means of a rotary transformer Hydro current can also be used for overtime work and lighting.

SCIENCE AND BUSINESS

In several British industries, native raw materials are now being utilized where before the war such materials were imported from the continent simply because the manufacturer did not happen to know that ample supplies of the same were at his very door, a fact of which he would have been informed had he consulted competent scientific authorities. This is well illustrated in the case of one of the largest steel corporations of England which, until 1914, had been importing from Austria, through a German firm, a certain material for lining its converters. As time wore on, and the supply diminished, complacency gave place to anxiety. Finally, the directors decided to call in scientific advice. They were referred to the geologists who informed them that a bountiful supply of the material in question was available in the immediate vicinity of their own plant. The information was acted upon, a shaft was sunk at no great distance from their furnaces, and, as a result, the company is now mining in sufficient quantities on its own account the material formerly imported.



Manufacturing the British 6 in. Mark XIII. H.E. Shell

By A. G. Webster*

AT the present time the munitions plants in Canada are producing more 6 in. H. E. shells than any other type, and in the particular plant covered in this article the methods used will be of some value in view of the fact that production has considerably exceeded contract requirements, thus indicating unusually high efficiency. In passing it may be mentioned that very good production records have been obtained in the past on other types of shell. To enable the reader to judge as to the size of the plant it may be stated that at the present time production is running at the rate of 3,700 shells in 24 hours with every possibility of the 4,000 mark being reached at no distant date.

The shell shop is divided into two sections, "A" and "B" plant. Each plant is distinct in its layout, but the system and character of the operations are identical. The machine tools used for certain operations vary in some cases, but the same results are being obtained, so there is in reality very little difference between the two plants, at least not sufficient to draw any fine distinctions and for the sake of brevity both plants will be included together.

The outstanding feature in the layout of this plant is the system of tables installed to facilitate the handling of the shells. After the shells leave the cutting off machine, at the first operation, they never touch the floor until they are boxed for shipping. Not only does this system tend to increase efficiency, but it also saves an enormous amount of time and energy, the latter being a particularly important factor when considering the weight of the 6-inch shell. A number of women are employed, which would be hardly possible except by having some system of handling the shells with a minimum amount of lifting and carrying. The tables extend in rows practically the full length of the shop while the machines are arranged in rows, in groups, on either side of the tables. In some cases as many as 5 rows of machines, with 4 in a row, are installed. The general system of drive is from line shafts motor-driven and hangers equipped with S K F ball bearings. The shells start one end of the shop, proceed up one side and down the other, finishing at the end where they started. Wherever possible air chucks are used with collet chucks or expanding mandrels according to the character of the work.

The shell which is being produced at this plant is the British 6-inch Mark XIII. high explosive. The forging weighs 120 pounds, is 6⅝ inches diameter and not less than 23 inches long.

Cut Off Open End

The first procedure is to mark the shell at the point where the open end has to be cut off. The shells are lifted from the ground to a table by an air hoist. A gauge is placed on the shell and a mark punched on the outside body, near the open end. The mark is gauged in relation to the bottom of the bore. The shells are then rolled along to the cutting-off machines supplied by John S. Hall & Sons, Brantford, Ont., and are arranged between rows of tables. The machines have two high-speed steel cut-off tools set opposite and operated simultaneously towards the centre by a cross feed screw which is operated by worm gears driven from the head-stock gear. The shells are lifted from the tables to the machines by pulley blocks and overhead runways, one for each machine. Production per machine per hour is 18.

Centering Base

The second operation, drilling the centre in base, is done on a machine equipped with an expanding mandrel and a sliding fixture holding a No. 5 combination drill and countersink. This fixture, which has an independent drive from the countershaft, is moved out of the way when the shell is placed on the mandrel and then placed in a central position. The handwheel on the spindle feeds the drill forward when forming the centre in the bore.

FIRST ROUGH TURN OPERATION ON A MONTREAL LATHE

*Associate Editor, Canadian Machinery

First Rough Turn

Bridgeford and Montreal lathes are installed for rough turning the body, which is the third operation. The Bridgeford lathes are driven through a friction clutch while the Montreal lathes have a clutch in the headstock and a friction pulley driven direct from the countershaft. The thrust-bearing is equipped with S K F ball bearings. The mandrel, which is of the short expanding type, has four rollers which grip the bore tight immediately the tool begins to cut. One roughing cut is taken the entire length of the shell. The tool used is "Stellite" welded tip, the cutting speed being 60 feet per minute with ⅛-inch feed. The rough turning reduces the outside diameter to 6.13 inches. Overhead runways and Wright hoists are installed for handling the shells between the tables and lathes. Production per machine per hour is 8.

Boring Operations

The fourth operation comprises the first and second rough bore and finish bore. Hepburn single purpose machines are used for this operation. They are equipped with Hyde air-operated chucks and S K F thrust bearings. The loose pulley is also equipped with S K F ball bearings. The first rough boring is done with a single pointed tool which roughs the straight part of the bore. The second rough boring is done with a boring-head, which roughs the bore, the contour and base. The third tool is similar to the second and it finishes the shell inside. The second and third boring bars have a straight cutter on the bar proper, while the end section or point carries the forming cutters for contour and base. Cutting lubricant is fed through each of the bars to the point. High speed steel is used for this operation, the speed for the roughing being about 60 feet per minute with a ⅛-inch feed. The bore is 4.24 inches in diameter after machining. Production about 15 per hour.

FORMING CHAMFER ON OPEN END OF 6-INCH SHELL

Rough Face Base

The fifth operation is cutting off the base, which is done on a number of cutting-off machines by various makers, principally the John S. Hall & Sons, Allatt Machine Tool Co., and T. H. Symington. These machines have universal chucks with a stop in the centre to fix the position of the shell. The lathe carriage is stationary and the cross slide carrying the tool post provides for the feed. A high speed steel tool is used for this work. Production 14 per hour.

Re-Centre

The base centre has been removed at the previous operation so the base has to be centred. The re-centreing is done on Le Blond lathes having expanding mandrels operated by Hyde air chucks. The tool holder or cross-slide holds a No. 5 combination drill and countersink. The drilling fixture is moved out of the way when putting the shell on the mandrel and then moved back to a central position. The feed is taken care of by the lathe carriage. In this case the shell rotates and the drill is stationary.

Second Rough Turn

Another rough turning operation now follows. This is the second and turns the shell concentric with the new centre. Le Blond and Davenport lathes are used on this work. The mandrel has self-tightening rollers, as used on the first rough turn. A "Stellite" tool is used at this operation, the speed being 90 feet per minute and feed ⅛ inch. The outside diameter is now 6.08 inches. Production 14 per hour.

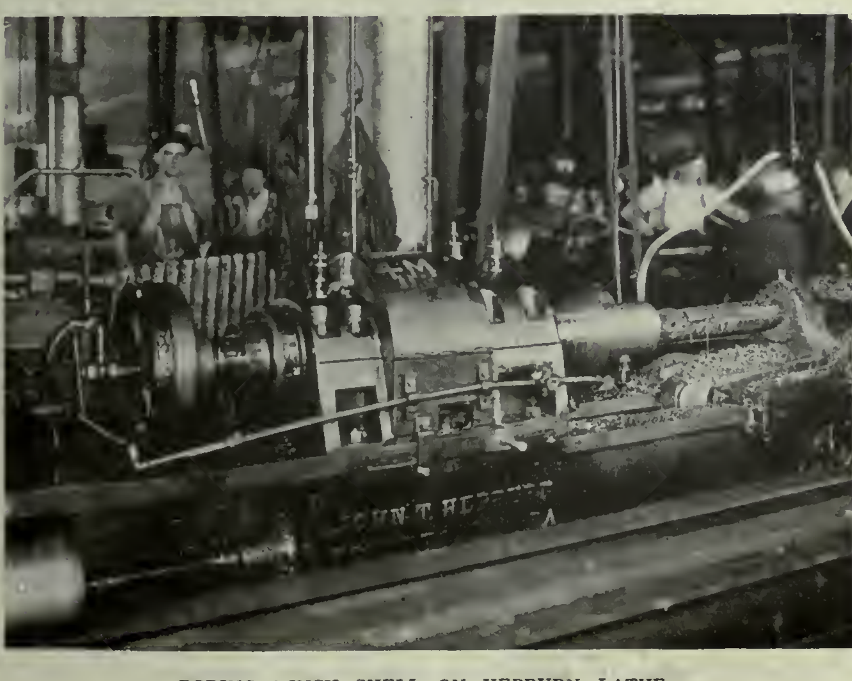
Chamfer Open End

At the eighth operation the open end is chamfered for about 2 inches down to relieve the nose for the forging. Hepburn lathes equipped with Hyde air chucks are used for this work. A fixture is mounted on the lathe carriage, having two tools, one is at an angle for hogging and forms the chamfer while the other is square and faces up the open end. The outside diameter of open end after chamfering is 5.14 inches. Production 60 per hour.

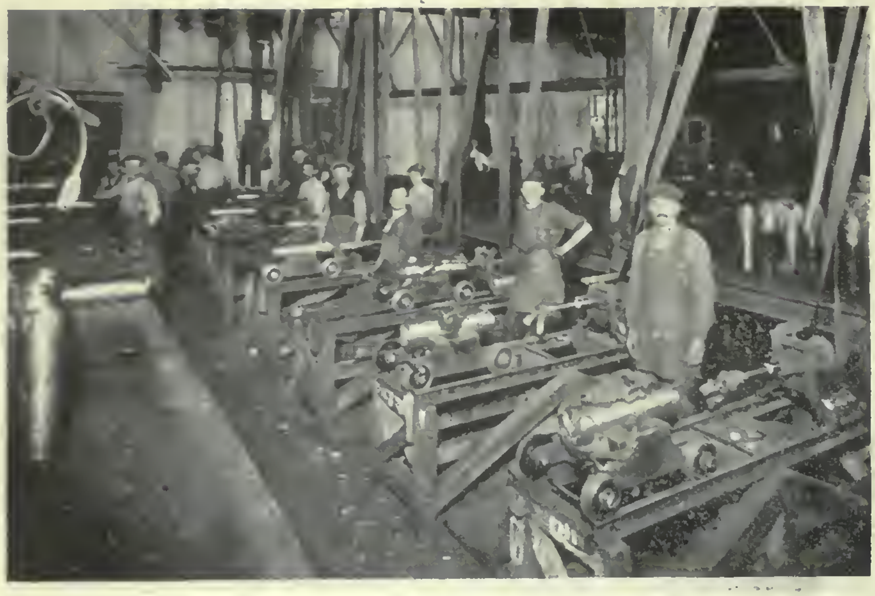
Buffing Bore

The continuity of the long table is at this point broken by a cross table. The shells which have been rolling from one operation to another, now are transferred to cross table and examined. A letter is also painted on the body to indicate more clearly the heat number. The heat number was transferred to the body from the base before the base was cut off at the fifth operation.

Near the cross table is a row of grinding machines for buffing the bore which is the ninth operation. The buffing machine has a long horizontal spindle, at the end of which are two short fingers, each holding a piece of abrasive material. The high speed of this



BORING 6-INCH SHELL ON HEPBURN LATHE.



BUFFING BORE 6-INCH SHELLS

spindle, 3,000 r.p.m., causes the fingers to fly out by centrifugal action. The internal buffing machines were built by the Roelofson Machine & Tool Co., Galt, Ont.

The shell which rests on a carriage fitted with roller-bearings is moved back and forth while the spindle is rotating and the bore being ground. This operation gives a smooth finish to the bore by removing tool marks. The spindles of these machines run in S K P ball-bearings and the countershaft is also equipped with these ball-bearings. The shells are then carried back to the cross bench and cleaned out.

Forging Nose

The tenth operation is forging the nose. In the "B" plant there are five "Mecol" six-hole furnaces, and three Perrin hydraulic presses. In "A" plant there are three "Mecol" furnaces and two Perrin presses. The pressure for these presses is supplied by a vertical, motor driven, triplex pump, built by the Canadian Boomer Boschert Press Co., Montreal. Accumulators are installed in connection with the presses and pumps. The furnaces are arranged in one row and have a gravity conveyor running the entire length in front. The shells roll from a table to the conveyor and are then pushed along the conveyor to the furnaces. The furnaces are oil-fired and the correct heat is judged by the appearance of the nose. Too much heat causes a coating of scale and too much air in the furnace will also produce the same result. If the nose is heated too far down it is liable to buckle when in the press.

The presses are situated in front of the furnaces and have an overhead runway. The shells are lifted from the furnace by tongs suspended from the runway and placed on the press table. The dies are in the head of the press and the table is pushed up by the ram underneath. When the nose has been forged the shells are carried by suspended tongs to a table. A continuation of the overhead system extends out into the machine shop and the shells are carried by tongs to another table where they remain until cool. The profile extends 6.28 inches from end of nose.

Ream and Seat Fuse Hole

A resumption is now made of the machining operations. The nose having been forged, the fuse hole can be machined. This operation is done on turret lathes or on engine lathes equipped with a turret. The machines used are LeBlond and Davenport lathes equipped with Hannifin air chucks.

The turret contains five high-speed steel tools. The first is a flat hogging drill for roughing the hole. The second is a single pointed tool for rough boring, while the third is a double cutter for forming the fuse seat bevel. The fourth is a single pointed tool for finishing boring the hole, while the fifth is a reamer for reaming the hole. The hole is 1⅝ inch diameter after this operation.

Finish Turn

The twelfth operation is finish turn on Le Blond, American and also Bridgeford axle lathes equipped with self-tightening mandrils, as used at the other turning operations. The profiling attachment is carried on brackets at the rear of the lathe. The brackets carry a shaft with a clamp attached, acting as a pivot for the radius bar which connects with the cross slide carrying the tool post. The tool starts cutting at the base end of shell and travels forward parallel to the shell up to the shoulder. During this time the carriage and profile attachment travel along together until the bar at the back comes up to a stop. When this bar hits the stop, profiling begins. The clamp being fixed to the bar remains stationary against the stop and therefore draws the tool post by means of the radius bar, thus forming the profile. The profiling attachment was developed at this plant. Before the shell is removed from the lathe the carriage is moved back to the base end, and the base diameter turned to 5.91 inches for a distance of 1½ inch from the base. The body is now 5.97 inches diameter outside. The radius of the outside profile is 11.92 inches. The tool used for this operation is "Stellite" 1 3/16 inch round and the cutting speed is 75 feet per minute, with 1/16 inch feed. Production 9 per hour.

Inside Profile

The thirteenth operation is forming the inside profile behind the nose. This is done on American lathes equipped with Hyde air chucks. A special tool is used for this work. It consists of a curved bar held in the tool holder, the bar having a curved high speed stetel cutter to form the profile to the required curve. The bar is put through fuse hole and fed up to the work by means of the cross slide upon which is the tool holder.

FURNACES AND PRESSES FOR CLOSING IN OPEN END AND FORMING NOSE OF SHELL

MACHINES FOR SANDBLASTING BASE OF 6-INCH SHELL

The radius of the profile is 11.92 inches. Production 8 per hour.

Rough Base Recess

Roughing the base recess and forming the radius is the fourteenth operation. The lathes used are principally Le Blond and Davenport equipped with Hannifin air chucks. There are also some Phoenix and Miller lathes equipped respectively with Hannifin and Hyde air chucks.

The tooling fixture is of special design and has two high speed steel tools. One is a square cutter for hogging out the base, while the other tool, which is close to it, forms the riveting strip and the radius. Production 15 per hour.

Finish Base Recess

This operation, the fifteenth, is similar to the preceding one except that the base recess only is machined. This is the finishing operation for the base recess which is ⅝ inch deep and 4.5 inch diameter. The machines used are practically the same as above but there is only one tool which is a plain high-speed steel cutter.

Copper Band Recess

At the next and sixteenth operation the recess, undercut and waves are formed for the copper band. Le Blond lathes with Hannifin air chucks are principally used for the operation. The fixture holding the tools is fastened to the lathe bed. The front tool forms the recess and waves, while the back tools form the undercut. The wave forming tool is oscillated by means of a cam on the chuck face, a spring being utilized to keep the roller on the fixture up to the cam. The back fixture has two undercutting tools which feed in at an angle of 20 degrees.

The feed for all the tools is taken care of by the lathe carriage. Attached to the carriage are two shaped bars, one for each fixture. As the carriage moves forward the bars cause the tools to travel in while cutting. When the waves and undercuts have been formed, a lever pivoted to the back fixture and carrying a small cutter, is brought over to clear up the recess. There are two waved ribs ¼ inch apart, and the recess on the outside is .67 inch wide and 8 inches from the base. The wave ribs have an angle of 70 degrees. Production 38 per hour.

Nose Recess

The seventeenth operation is forming the recess in nose behind the threads. The recess is 2 inches diameter and about .14 inch wide. The operation is performed on Le Blond lathes equipped with air chucks. A bar in the tool holder has a small high speed steel tool at the end for cutting the recess. Production 50 per hour.

Threading Fuse Hole

The eighteenth operation, threading the fuse hole, is done on Holden-Morgen and Cowan thread milling machines. The shell is put into the head of machine from the back and the cover fastened on. The milling hob is on a separate fixture, with independent drive. The shell makes one revolution while the threads are being cut. A high speed steel hob is used and the cutting speed is 75 feet per minute. The threads are 14 to the inch, right hand. Production 20 per hour.

Sand Blast

At this stage the shells are washed in a solution of soda and hot water to remove the grease, etc. They are then laid in a horizontal position on revolving rollers and dried with compressed air.

The next operation, No. 20, is sand-blasting the bore. A number of machines built by the Gray Mfg. Co., Toronto, are installed for this operation. The shell is held in a fixture nose down and slowly rotated while the sand blast is injected from below. Sand-blasting removes the tool marks and gives a smooth finish to the inside of shell.

The shells now undergo the preliminary Government inspection, all the shells being carefully examined, gauged and weighed.

Base Plate

The base plate which is riveted into

RIVETTING BASE PLATE WITH AIR HAMMER

FINISHING BASE RECESS AND FORMING RIVETING STRIP.

the shell base is a drop forging 4½ inches diameter and ½ inch thick. The base plates are turned up and faced on Davenport lathes equipped with air chucks, in two operations. At the first, the diameter is turned and bevel formed while at the second the plate is faced. When turning the diameter the plate is held up tight by pressure from the tail centre, against a knurled driving plate. When the plate is being faced it is held in a chuck. Davenport and American lathes are used principally for this operation. The base plates are fitted in the base recess after the preliminary Government inspection.

Copper Band

The shells are rolled along the table to have the copper band put in the recess prior to being pressed in. They then go to the presses.

The copper band presses were built by the West Tire Setter Co., and are operated by hydraulic power. An eye bolt is screwed into the fuse hole and the shell is lifted from the table to the press by a chain hoist. A pressure of about 1,300 pounds is applied twice, the shell being moved round between each application. The shell is then lifted out and rolled along the table to the base rivetting machines.

Rivet Base Plate

Rivetting the base plate is the twentieth operation, which is done on a machine built by the Roelofson Machine & Tool Co., Galt, Ont., from suggestions furnished by the firm to whom the machine was supplied. The machine is similar in design to the copper band turning machine built by the same concern, but it has one or two special features embodied in its construction. The spindle has a worm gear drive and is fitted with a quick acting collet chuck. The spindle rotates at 10 r.p.m. The machine has a fixture on the bed for holding the air hammer at the required angle. During the first two revolutions the strip on the base is rivetted over. The hammer is then moved in a short way and the operation completed. A feature of the machine is the accuracy obtained in the method of holding and operating the air hammer.

Face Base

The bases are now faced up, twenty-sixth operation, on a row of "American" lathes equipped with air chucks, an ordinary facing tool being used.

The shells then travel along the table, pass over the scales, and are weighed. The mean weight of shell at this stage is 85 pounds, 12 ounces, the high being 86 pounds 3 ounces and low 84 pounds 14 ounces.

The following marks are then stamped on the base: 6-in. H. R. XIII. L., date, and firm's initials. The heat number is stamped on the body.

Tap Fuse Hole and Reseat

A number of minor operations now follow, the first being to tap the fuse hole, which is done with a hand tap. The fuse seat is then finished on a drill press, having a special reseating tool. The fuse hole is then retapped.

The shells are again washed in a solution of soda and hot water and dried by compressed air while being revolved on rollers fitted into the table. A Gray sand blast machine is installed in this department for removing varnish from the shell bore if they have failed to pass inspection after varnishing.

Varnish and Bake

When the shell is being varnished it is laid on revolving rollers fitted in the table, sprayed inside with varnish and brushed. Only a very thin coat of shellac varnish is applied.

The shells are then baked for two hours at a temperature of 400 degrees. The oven, which is heated by electricity will hold three trucks or a total of 80 shells at a time. The shells are placed on the trucks, which are mounted on wheels, and placed in the oven. When the baking process has been completed the shells are removed to a table to cool off. The varnish is then inspected. A "Tycos" electric contact type pyrometer is installed in connection with the baking oven.

Turn Copper Band

When the shells are cool and the threads and container seat have been cleaned, they are moved along to have the copper band turned. This operation is done in a Roelofson Machine Tool Co. band turning machine. The forming tool is held in a tool post at the front, and the band is finished with a hand-turning tool. The hand tool removes the burrs at the side of band down to the shell body. The production is 120 per hour.

The final inspection is made after the copper band has been turned. This is a Government inspection and all the shells are carefully gauged, weighed and examined. A plug is screwed in the fuse hole and the shells are then greased and packed two in a box.

The final weights are as follows: High 85 lbs., 15 oz. 2 drs.; mean, 85 lbs., 8 oz., and low, 84 lbs. 10 oz. 11 drs., the tolerance is thus about 1 lb. 4½ oz. The mean weight after the inside profile has been formed is 87 lbs., 4 oz., and at the preliminary inspection the mean weight is 82 lbs., 11 oz. The base plate weighs 2 lbs. 1 oz. finished, and the copper band 18 oz. rough and 12 oz. fin-

TURNING COPPER BAND 6-INCH SHELL

ished. The shells go through the various operations in series of 300. There is no tensile test for 6-in.shells, but two shells are taken from each series, one which is cut up in four sections and one proof shell for the firing test. The test shells are taken out at the final inspection.

CUTTING TEST PIECES FROM SHELLS

A new machine for cutting test pieces from shells by means of an oxy-acetylene torch, has been developed and put on the market by the W. R. Carter Welding Co., York street, Hamilton, Ont. The machine is being built for 6-inch, 9.2-inch and 12-inch shells.

The frame of the machine consists of angles welded together, forming a stand for carrying the shell and cutting outfit. As will be seen from the illustration, the oxy-acetylene torch is carried on a fixture which can be moved lengthways on the machine as well as across. The fixture is traversed by means of a screw and handwheel.

The shell as shown in the illustration is resting on longitudinal rollers revolved by the crank through gears. The test piece is first cut out from the shell body as shown, the fixture carrying torch travelling along while cutting in a longitudinal direction. When cutting across, the shell is turned by means of the crank, while the torch is in operation. While the base is being cut off the torch is stationary and the shell is turned round. The complete operation has been done in four minutes.

WOMAN IN WORKSHOPS

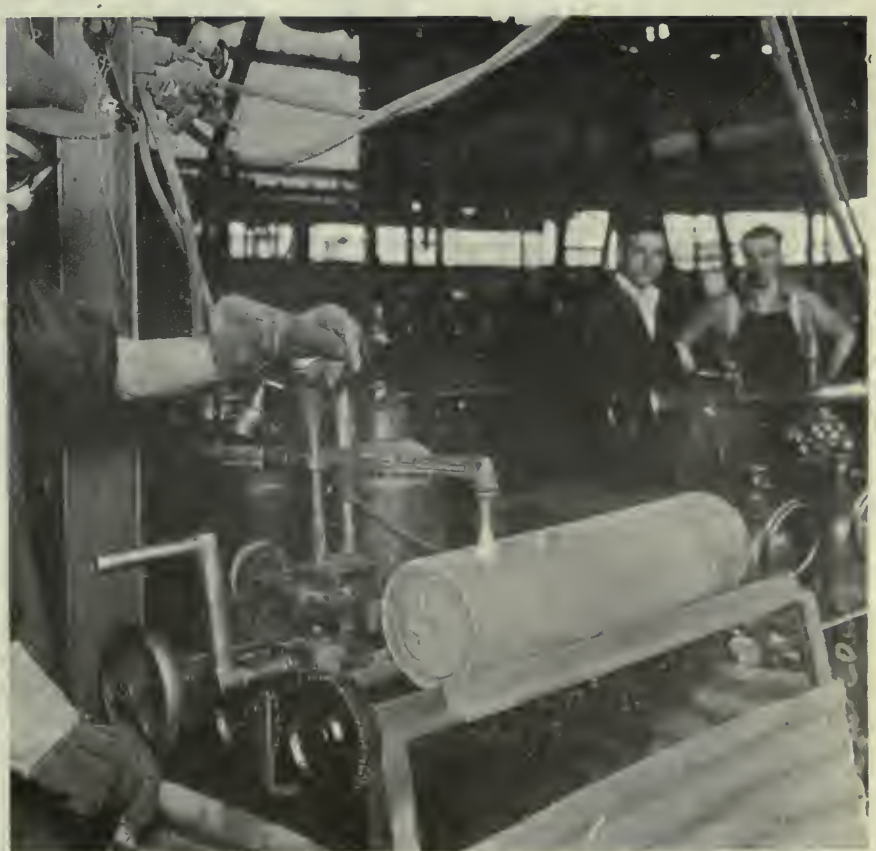
By R. E. D.

There is very little attention being paid to the future of female labor in engineering, although it is generally admitted that it will be one of the most difficult problems we shall have to solve during the period of reconstruction. It is surprising that women were not engaged in engineering before the war considering that they were employed in many industries that were manifestly less suited to them; but there is some consolation in the thought that insular conservatism was not responsible for this, as even in Germany their value was not realized until some sufficient male labor could not be had. They have become so important a part of the producing machine now that it is difficult to see how they can be ejected from it when the most pressing need for their labor is past. This is looking at it from the purely economic standpoint and ignoring the social danger that would be incurred by throwing these women on the labor market. Many of them will return to their domestic duties when their husbands return from the army, but many more will desire to make their new vocation their life work, and it is in the interests of industry that they should be allowed to do so. But their sphere of usefulness is limited, and their greatest value is not realized when they are employed at work for which they are unsuited. For example, girls or women may be useful in the coreshop, but the heavy labor of the foundry floor is the man's work. It would have been a wise policy if, when it was first determined to introduce women into the engineering workshops, a committee of experts had been appointed to consider any advice on the best method of training them for suitable classes of work. We might now have had a great army of really skilled women workers who would have released more men for the colors.

It is erroneous to suppose that the only opponent of woman labor is the skilled male worker. The foremen's opposition has been potent during the war. The workman's prejudice is logical, and is usually based on the fear of undercutting. The history of woman in industry is not pleasant reading. Invariably she has been used to keep down the rate of wages, and consequently, lower the living standard. The only way to eliminate the risk is to abolish sex rivalry. If workmen would open their unions to woman, they would find them loyal members of their craft. It may be admitted, however, that women in certain work require more help, because of the physical weakness, than men, and it may thus be economical to an employer to pay them the same rate of wages as men. This difficulty could be adjusted amicably. however, between the workers and employers in conference.

The war period has seen new developments in engineering. The petrol engine has advanced wonderfully, and the manufacture of aeroplanes, while it is not likely that it will continue in its present conditions or proportions, is a permanent addition to engineering activity. It is probable that it is in motor car and aeroplane work that women will score her greatest successes. although even in the general works there is room for her. It will be interesting to observe the effect of women's entrance into engineering shops on workshop conditions. She enters with a mind unbiased and unbittered by the memories of industrial struggles and unprejudiced by worn out customs. Women may be inherently no more conscientious than men, but the "ca canny" policy is not likely to be favored by them; indeed, it is more a disease than a policy, a disease which has become chronic because of the stupid relations between employers and men in the past. Apart altogether from their influence on wages, however, it is probable they will demonstrate a zeal of reforms effecting the hygiene and sanitary conditions of the shops, which will make for efficiency and, consequently, increased productivity.

ACCURACY is a prime factor of conservation. An American engineer stated recently that he had seen a British plant employing eleven thousand persons making over American-made fuses.



CUTTING TEST PIECE FROM SHELL FORGING BY OXY-ACETYLENE TORCH.

The Chemist and Metallurgist in the Munitions Industry

Growth of Munitions Industry Stimulates Demand for the Technically Trained Man—Particularly so in Chemical and Metallurgical Fields—Every Plant of Sufficient Size Now Recognizes Need for Skilled Supervision of All Plant Processes

By F. E. Gardiner

Chief chemist and Metallurgist for the Dominion Bridge Co., and the Dominion Copper Products Co.

THE marvelous growth of the munitions industtry in Canada during the past three years has ed to an ever-increasing demand for men of technical training along chemical and metallurgical lines. Before the war it was the exception rather than the rule to see men of this training employed, even in the large industrial plants; to-day almost every plant engaged in any form of munition activity employs at least one man thoroughly trained in chemical and metallurgical practice. The duties of the works' chemist and metallurgist are many and varied, depending on the work in which his engaged, as well as the laboratory facilities at his disposal.

CHEMICAL LABORATORY AT DOM. BRIDGE CO.

Since the spring of 1915, when they first embarked on their munitions activities, the Dominion Bridge Co. and the Dominion Copper Products Co. have manufactured a wide variety of products. All sizes of shells, from the 18 pounder shrapnel to the 9.2 high explosive shell, British, Russian and Belgian cartridge cases, copper driving bands from 3 inch to 9.2 inch, marine engines and boilers, brass and copper tubes and sheets, and miscellaneous smaller components of many kinds, have been some of the munition products which have been manufactured at these plants. Looking at the question from the light of their experience I will endeavor to show in a general way the part the metallurgist plays in the different operations which go to make up the finished product. The same work that is carried on by the metallurgical department in the plants of these two companies, will be carried on to a greater or lesser extent in any of our large munition plants.

The general work of the chemist will lie along the following lines:

1. Chemical analysis of raw materials or finished product.
2. Supervision and regulation over all heat treatment necessary to produce the finished product.
3. Physical testing of all materials, both in course of manufacture and as a finished product.
4. Microscopic examination of the various materials used.
5. Miscellaneous testing and experimental work.

Heat Treatment of 75 m.m. U. S. Shells

The specifications laid down for nearly all shells of a small calibre call for them to be heat treated, after which they must satisfy certain physical requirements. The United States 75 m.m. shell after treatment has to have an elastic limit of 45,000 lbs. per in., an ultimate tensile strength of 90,000 lbs. per sq. in., and an elongation of 15 per cent.

In heat treating steel to achieve any desired result it is a great advantage to know beforehand the chemical composition of the steel. Here is where the chemist comes in. He makes an analysis of the steel and passes it on to the metallurgist who uses this information as his experience directs. In hardening shells of any kind the following are the main factors influencing the success of the operation.

1. Uniform heat to the correct temperature.
2. Good quenching medium, kept at a low temperature.
3. Uniform tempering to the correct temperature.

The failure to observe any of these three factors will often lead to a failure in the steel and cause serious delays in the production of the shop, to say nothing of the additional cost of retreatment.

Uniformity of heating is dependent on several conditions, chief of which are the nature of the furnace used, the kind of fuel, and the efficiency of the labor. As a general thing it may be said that large furnaces of the automatic and mechanical types, using either oil or gas as a fuel, will give better and more uniform results than the smaller furnaces of the batch type. Their radiation losses will also be much smaller and thus lead to increased efficiency and lower fuel costs in operation. However excellent results can be secured from the batch type of furnace also, although these results are—to a much greater degree than in the case of the larger type of furnace — dependent upon the care and supervision exercised over their operation as well as the quality of the labor operating them.

Another factor that greatly influences the uniformity of heating is the use of pyrometers. Any good rugged thermocouple of the base metal type used with a high resistance indicator is suitable, and it will be found that once the men get accustomed to working by pyrometer control, using their judgment as to time and color as a check against the pyrometer readings, very uniform and successful hardening will result.

A good quenching oil should have a high flash point, high thermal conductivity, a low volatility, good specific gravity, and uniform viscosity. A well blended fish and mineral oil possessing a flash point of 400 degrees Fahr. and a specific gravity of about .900, will generally be found to meet these requirements. The reason for keeping the oil at as low a temperature as possible is something that is obvious to everyone. An oil that is continually kept at a high temperature suffers a great decrease in quenching power and is bound to distil off a certain fraction of its lighter and more volatile constituents, leaving the heavier ones behind, which still further lessens its effectiveness.

The correct temperature for hardening and tempering sheel steel depends upon its critical point, which is determined by the percentage of carbon present. In general, the lower in carbon the steel is the higher the temperature it is raised to for hardening, and the lower the temperature it is drawn back to. The range of temperature that we have found to give good results in hardening 75 m.m. shells varies from 1,500 to 1,575 degrees Fahr., according to the carbon content, and the tempering range from 950 to 1,100 degrees Fahr.; the carbon content of steel treated under these conditions has varied all the way from .35 to .55 per cent.

Forging 6 Inch and 9.2 Inch Shells

Another branch of the munitions industry in which great strides have been made is the manufacture of shell forgings. All sizes of shells from the 18 pounder weighing only 25 lbs. in the rough, to the big 9.2 inch shell weighing 375 lbs. have been successfully forged in this country. The Dominion Bridge Company have been forging the 6 inch high explosive shell for the Imperial Munitions Board for the past two years and are now making 9.2 inch forgings for the American government. The billets are heated in underfired furnaces equipped with Ferguson burners and use oil as a fuel, and are subsequently pierced on 700 ton Southwark hydraulic presses. After forging the shells must pass certain physical tests.

The British specifications for forgings of this size call for a yield point of not less than 19 long tons per sq. in., a tensile strength of from 35 to 49 tons, and a minimum elongation of 17 per cent. Needless to say these requirements are not always met with, so that a subsequent treatment of the steel is very often necessary.

The chief cause of failure will usually be found in the overheating of the steel before forging, and it is very hard to make the average heater realize the great effect that any severe overheating has upon the physical properties of the steel. Constant supervision and care over the heating of the billets is the chief essential to successful forging work. Billets which have been slowly and uniformly heated to a temperature of from 1,900 to 2,000 degrees Fahr. will be found to forge just as easily as those whose heating has been hastened and which emerge from the furnace dripping at a temperature anywhere up to 2,300 degrees Fahr. Not only will the correctly heated billet forge just as readily as the overheated one but the results from its physical tests will be immeasurably superior and the steel will have a very much better structure. Knowing the analysis of the steel we can often greatly affect its physical properties by the method of cooling after forging. Cool high carbon steels as slowly as possible, the reverse for low carbon ones.

For purposes of heat treating the forgings which fail to pass the tests may be classified as follows:

Forgings failing in yield or tensile.
Forgings which fail in elongation.
Forgings which exceed the high tensile limit.

The failures of forgings from the first cause may generally be ascribed to overheating, but it often happens that the steel is so low in carbon that the ordinary methods of cooling after forging are not sufficiently rapid to enable it to pass the physical tests even if it has been forged at the proper temperature. The steel in any forging whose failure has been due to overheating alone can usually be brought into a condition which will enable it to pass the test, by the heat treatment known as "normalizing." This merely consists of heating the forgings slowly and evenly to a temperature, well above their critical range and holding them at this temperature for a length of time which depends upon the severity of their previous treatment, and the results of their first physical tests, removing them from the furnace, standing them on end to cool, as far apart as possible, and allowing a good circulation of air to pass around them. A temperature of 1,550 degrees Fahr. will be found to be good average practice for this operation, which should be carried on as a continuous one, if possible.

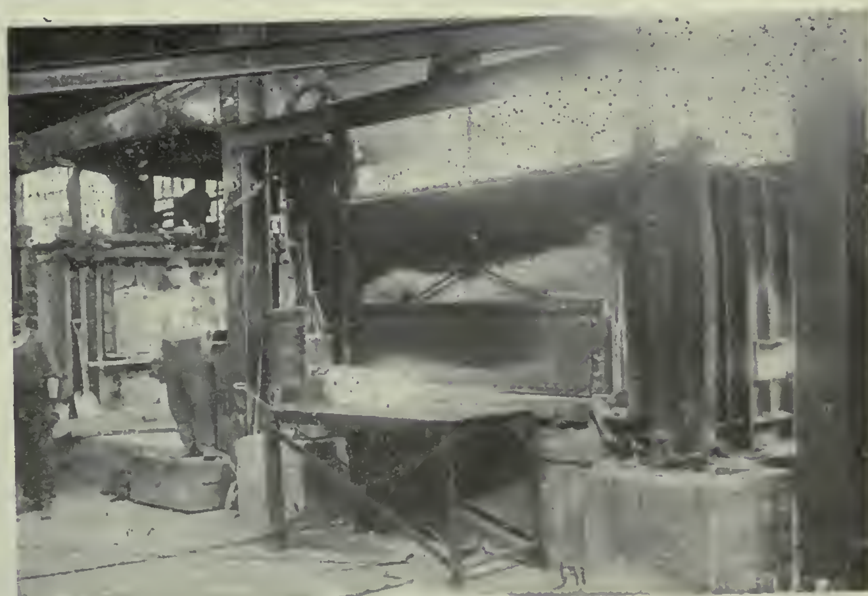
Those forgings whose failure is due to a combination of low carbon and overheating will require a quicker cooling than that given by the normalizing treatment. This treatment is known as "air cooling," and as its name implies, it cools the forging by the artificial use of air. The apparatus used for this purpose differs in construction in almost every plant using it, but in the main its general features are the same. The apparatus designed and adopted by the Dominion Bridge Company cools four 6 inch forgings every 9 minutes and consists in essential, of an inner pipe of 3 inches diameter, which enters the shell, and an outer casing of 8 inches diameter into which the shell slides. The outer casing is hinged so that when the shell enters, the hinged section is clamped down and the air blast turned on. The air used is at a pressure of about 8 ounces, and is supplied by a No. 9 Sturtevant blower. The temperature of the shell as it enters the apparatus, varies from 1,550 to 1,660 degrees and its cools in 9 minutes to about 600 degrees Fahr.

The results achieved by the use of this appliance are very good and the tensile strength can often be raised anywhere from 2 to 8 tons, with a corresponding increase in yield. This plant has successfully treated steel by this method, as low as .35 per cent. carbon.

Failure in elongation is usually caused by overheating, but also may be due to forging at too low a temperature. This latter condition, however, is seldom met with in everyday forging practice. Another cause of low elongation is to be found in the nature of the steel itself, flaws often appearing in the fractured test bars. It is almost impossible to do anything with steel whose failure is due to flaws, but where the failure in elongation has been caused by overheating, the steel will usually respond to the normalizing treatment, or if not, to a light anneal.

Failures on account of high tensile can generally be traced to the high percentage of the hardening elements, carbon and manganese in the steel, to overheating or to a combination of both. In order to lower the tensile strength of a steel it is necessary to retard the speed of cooling, or in other words to anneal it. For steel possessing very high physical properties, with a high percentage of carbon and manganese, furnace cooling may be necessary, but as this is a very expensive proposition and also greatly slows up production, it is only resorted to in cases of extreme necessity. Removing the forgings quickly from the furnace after they have reached and been held at the desired temperature long enough, piling them in layers in an iron box or pit, carefully protecting them from all drafts, and covering them with a heavy layer of ashes, will invariably be found to give the desired results. The tensile strength may easily be lowered 5 tons by this method of treatment and production will not be held up as in the case of furnace cooling.

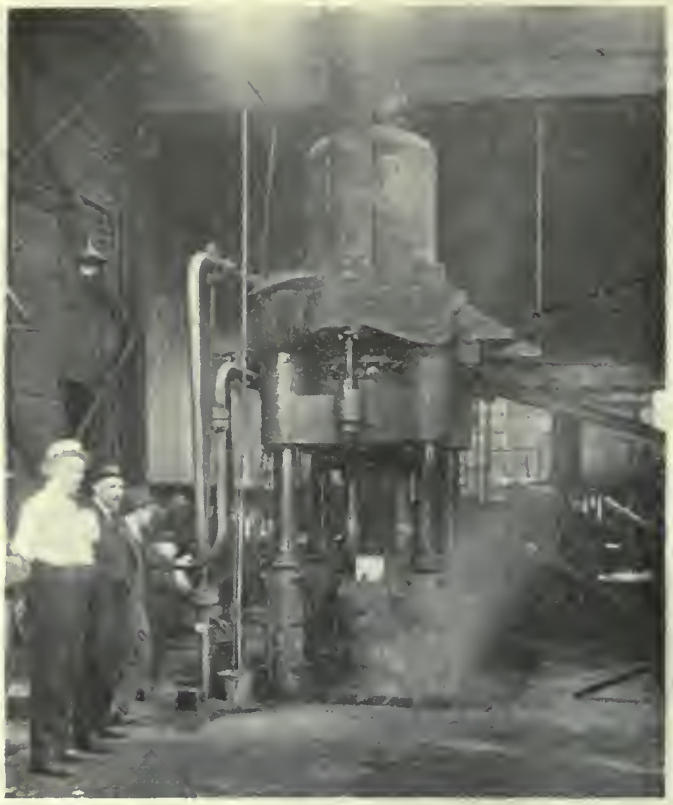
In treating forgings by any of the above processes, it is needless to say that a knowledge of the chemical analysis of the steel treated, as well as the result of its previous physical test, is necessary to achieve the best results. Careful temperature control, which can only be obtained by good pyrometer regulation is also very essential.



HEATED 9.2 BILLET EMERGING FROM THE FURNACE.

Treatment of Marine Engine Forgings

The building of marine engines is another new industry to a large number of plants in this country. Every marine



FORGING 9.2 SHELLS AT THE PLANT OF THE DOMINION BRIDGE CO.

engine has to have a large number of its parts, such as connecting rods, piston rods, crank shafts, etc. made out of forged steel. These forgings all have to be annealed and have to meet very exacting physical requirements. Take for instance Lloyd's specifications for marine engine forgings. These specifications call for a tensile strength of from 28 to 32 tons per sq. in., area of the test piece being ¼ inch, with a minimum elongation of 25 per cent. over 2 inches for steel of 32 tons tensile, and 29 per cent. for steel of 28 tons tensile. In addition to this tensile test a bar cut from the test coupon of section 1 inch by ¾ inch, must stand bending cold through an angle of 180 degrees.

A steel that will conform to these rigid requirements is not always easily attained owing to the enormous and ever increasing demands upon the steel mills. Such being the case, it is the duty of the metallurgist to use whatever steel he can obtain, if it has any chance at all of passing specifications, and endeavor to put this steel in such a condition after forging, by an intelligent application of the rules of steel heat treatment, that it will conform to the required physical requirements. Generally speaking, when a steel of any given carbon content possesses its lowet tenile properties, it also possesses its maximum, or very nearly its maximum, ductility. Thus, if we are using a steel whose carbon content is on the high side, this steel must be annealed very carefully, and slowly cooled, in order to meet the physical requirements as given above.

Slow cooling, especially through the critical range of the steel, enables the maximum amount of ferrite, or pure iron crystals to separate out from the iron-carbon alloys, and this gives us the results we are after; that is, low tensile strength and high ductility. Sometimes even this treatment will not enable the steel to successfully pass the bend test, in which case a double annealing may be resorted to. This consists in heating the steel well above its critical range, say to 1,500 degrees Fahr., slowly cooling in the furnace to 1,200 degrees, reheating to just under the above critical point, which depends upon the carbon content of the steel, but is generally in the neighborhood of 1,350 degrees, and then allowing the steel to cool in the furnace. This treatment will invariably raise the tensile a little, but gives the steel great ductility and cold bending properties. The steel also shows a large reduction of area and breaks with a well cupped silky fracture.

Steel low in carbon should not be given such a thorough anneal and should be allowed to cool in the air whenever possible. Our own experience has been that any steel ranging from .25 to .35 carbon. and from .40 to .80 manganese, will meet these requirements if intelligently handled. A steel that will always give good satisfaction for marine engine work would be one of .30 carbon and .50 manganese. If a steel of this composition is carefully annealed at from 1,450 to 1,500 degrees its physical properties will always be found to come within the limits laid down above.

The method of handling any forging work of this character in use at the plant of the Dominion Bridge Company is as follows: Every billet which comes into the shop is numbered consecutively, drillings taken and a chemical analysis made. When forgings are made from this particular billet, the original billet number is stamped on each forging and also on the test coupon, which is left on the end of one of the forgings made from every billet. In this way one test covers all forgings made from the same billet and all duplications of testing is thus avoided. The forgings are grouped together in the annealing charge, according to the chemical composition of the billet from which they were made, and all forgings of approximately the same chemical composition are annealed together and receive identical treatment.

Cast House Practice of the Dominion Copper Products Co.

Passing now from the ferrous branch of metallurgical operations as examplified by the products of the Dominion Bridge Co., we come to the non-ferrous field in the Dominion Copper Products Co. From a metallurgical standpoint one of the chief differences between steel and the non-ferrous metals and alloys such as copper and brass, is the fact that we can bring steel from a dead soft to a glass hard condition by simply heating it above its critical point and quenching it in water. Such is not the case with copper or brass. In order to harden either of these metals it is necessary to change their structure by the application of some mechanical strain, and the

FURNACE USED FOR HEAT TREATMENT OF FORGINGS SHOWING AIR COOLING APPARATUS IN PLACE.

CASTING BRASS TUBES IN CAST-HOUSE OF DOMINION COPPER PRODUCTS CO.

greater this strain is the harder the metal becomes, with a consequent decrease in ductility.

In any copper or brass rolling mill the first place where any chemical or metallurgical work occurs, is in the cast house, where the different alloys are made. The raw materials that enter into the composition of the different alloys are first carefully sampled and analysed to insure that no foreign elements are added to the alloys by impurities existing in the virgin metals. Copper, zinc, tin and lead, are the chief metals used in rolling mill alloys. After the virgin metals have satisfied the chemical requirements, the charge for any given alloy is weighed out into pans and conveyed to the cast house to be melted and cast into different kinds of moulds. The furnaces used for melting at the plant of the Dominion Copper Products Co. are of the pit fired type, the fire chambers being 15 by 15 inches in cross sectional area, with a grate at the bottom on which the fuel and the crucibles rest. The fuel used is anthracite coal and the draft for combustion is supplied by stacks 86 feet high and 2 feet 8 inches in diameter, each stack supplying 20 fires.

The charge is melted in graphite crucibles of different sizes, holding from 160 to 220 lbs. In making ordinary cartridge brass the procedure is as follows: The scrap is placed in the bottom of the crucible and the copper ingots are laid on its rim to heat up. After the scrap has melted, about a handful of coarse salt is added, then the copper, and the charge is completely covered with charcoal. When the copper has melted the spelter is added little by little about 10 or 15 minutes before pouring. The average time for a charge of 200 lbs., including charging, melting and casting, is about two hours. The molten charge is then poured into moulds and allowed to cool.

The chief alloys made are Muntz metal, an alloy of 60 per cent. copper and 40 per cent. zinc, used chiefly for condenser heads and tubes made by the hot piercing process; Admiralty metal, 70 per cent. copper, 29 per cent zinc, and 1 per cent. tin, used for condenser tubes on account of its great resistance to corrosion; cartridge brass, 70 per cent. copper and 30 per cent. zinc; 2 and 1 brass, as its name implies, an alloy containing 2 parts of copper and 1 of zinc; and several kinds of bronzes which generally contain varying amounts of tin in addition to the copper and zinc.

In order to insure uniformity of product it is necessary that frequent samples of the various mixtures cast be taken daily. This is done by the foreman caster, who marks the number of the mixture on the sample button, and it is then sent to the laboratory and analyzed. Any variation from the desired analysis is rectified by changing the mixture, in this way the different alloys are cast to a composition very closely approximating that desired.

One of the main objections towards the melting of copper and zinc alloys in fuel fired furnaces is the unsanitary conditions existing in the cast house, especially in the summer months, and the consequent inability of the plant to keep experienced help. Other objections are to be found in the high cost of fuel, crucibles and labor, and the high metal losses, generally due to the volatilization of the zinc. All these facts contribute to a feeling among brass men that a solution of these difficulties will be found in the electric furnace. Numerous electric furnaces have been tried out in the various mills of the United States during the past two years. The experience derived from these different experimental furnaces has seemed to show that an electric furnace of the induction type is best suited for the melting of these brasses high in zinc. This type of furnace is capable of very accurate heat control, has a high thermal efficiency, and keeps the metallic losses down to a very low point. The Dominion Copper Products Co. is at present installing an induction furnace of the Foley type, having a melting capacity of 1,000 lbs. per hour. The electric furnace as applied to brass melting is only in its infancy, but if it meets with anything like the same success that it has in the steel industry it will eventually find a very wide application in the non-ferrous field.

Copper Refining Furnaces

In any rolling mill handling copper there is always large scrap accumulations which it is not economical to return to the cast house for remelting. Such products are usually in the form of light turnings, metal recovered from cast house ashes, mill sweepings, black copper from the cupola and miscellaneous copper scrap of all kinds. To handle this metal, as well as other metal they receive from outside sources, the Dominion Copper Products Co. have two copper refining furnaces of 15 and 25 tons capacity per 24 hours. These furnaces are of the ordinary reverberatory type, fired by

CASTING COPPER SLABS.

soft coal. They are set up on cast iron plates resting on brick piers, and the bottom and the inside of the furnace which come in contact with the molten copper, are made of silica brick. The draft is supplied to each furnace by meaus of a brick-lined flue of two feet interior diameter, which leads into a 60-foot firebrick-lined stack, of three feet interior diameter.

A charge is tapped from each furnace every 24 hours and the refined copper is either cast into ingots for use in the cast house, bowl cakes to be drawn out into tubes or bands, or cake copper to be rolled out into sheets. The moulds are placed on a circular rack revolving about a central post by which it is supported. The molten copper is tapped from the furnace into a clay-lined tilting spout, and from there into the moulds.

A typical analysis of the copper which comes from these furnaces would be. copper 99.87 per cent., oxygen 0.08 per cent., other impurities 0.05 per cent. This percentage of oxygen which exists in copper in the form of cuprous oxide, is necessary, as it enables the copper to be cast free from blowholes and also checks the ill-effects of any other impurities which may be present in the copper. Copper containing this amount of oxygen is in its "tough pitch" condition, and it is in this state that it exhibits its best physical properties. When fractured it should show a rose pink color and have a silky structure.

During the process of refining copper considerable slag is made, the amount and composition of this slag depending to a great extent on the nature of the charge to be refined. The following is a typical analysis of a refined slag: Copper, 40.0 per cent.; silica, 29.5 per cent.; iron, 9.4 per cent.; lime, 2.5 per cent.

As will be seen from the analysis this material is very high in copper and consequently of considerable value.

BACK VIEW OF THE 15-TON FURNACE SHOWING CHARGING FLOOR.

Black Copper From the Cupola

The next step in the scheme of metallurgical operations is therefore to recover this copper from the slag. This is done by smelting the slag in a cupola, using coke as a fuel and roasted pyrites and limestone as a flux. Besides the refining copper and fluxes, the charge usually consists of mill sweepings, fine material recovered from the cast house ashes, ashes from the cupola flue, and old bricks from the worn out refining furnace linings which are generally impregnated with copper to a considerable extent. These various materials are weighed and charged into the cupola in regular sequence, as many as 75 charges being melted down in 24 hours, and from 5 to 7 tons of black copper averaging 95 per cent copper recovered per day. This material goes back to the refining furnace and completes the cycle of operations.

Daily analyses are made of the slag from the cupola. This is necessary in order to keep it of the proper composition to get the requisite degree of fluidity, and the right fluxing action to insure a good copper recovery. The fluxes that are used are also sampled and analysed as any considerable amount of impurities present in them would have deleterious effects upon the melting operations. For instance, the occurrence of much alumina in the limestone with the presence of much sulphur in the pyrite under would form a quantity of copper matte which would lead to considerable trouble in the subsequent refining.

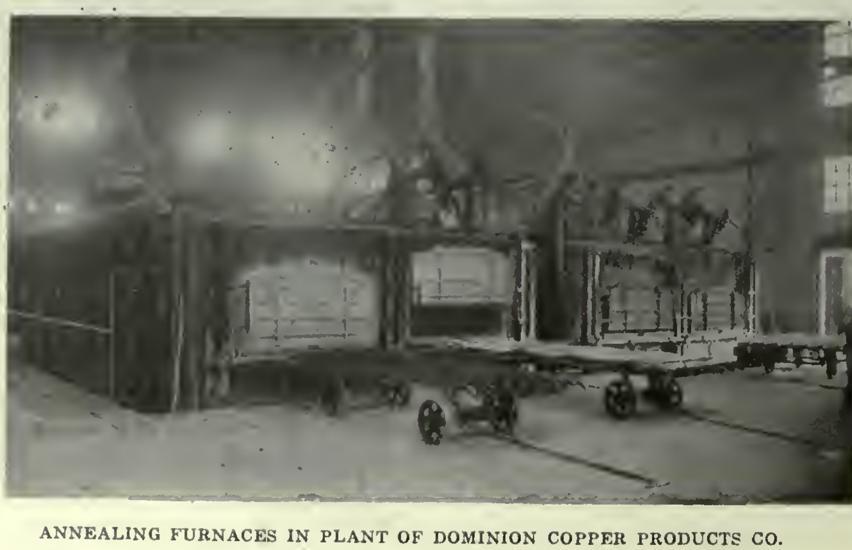
Annealing of Brass and Copper

Another part of the metallurgist's work in a brass rolling mill deals with the annealing of the material in the process of manufacture. After a certain amount of work has been accomplished on either brass or copper it is necessary to anneal it before more work can be performed. Annealing changes the highly distorted and elongated structure of rolled brass to a uniform crystalline structure and the metal becomes soft and ductile. The temperature and time of annealing depends upon the previous work performed on the brass and also upon the degree of softness required. To anneal brass or copper to a dead soft condition a uniform heat of from 1,200 to 1,250 degrees Fahr. will usually be found to be sufficient. The same applies to the heat treatment of brass as to that for steel, namely, that good temperature control cannot be effected without the use of accurate pyrometers.

The annealing furnaces in use at the plant of the Dominion Copper Products Co. are of the underfired type, using oil as a fuel. The material to be annealed is loaded upon sheet iron pans, drawn into the furnace by long hooks, passes through the furnace and out at the opposite end where it is either sprinkled with water or left to cool by standing in the air.

Microscopic Examination of the Metals

The foregoing resume of the everyday work of the plant chemist and metallurgist has dealt with his work mainly from a strictly chemical and metallurgical standpoint. Another branch of work which comes within the field of the met-



ANNEALING FURNACES IN PLANT OF DOMINION COPPER PRODUCTS CO.

TAPPING BLACK COPPER FROM THE CUPOLA, DOMINION COPPER PRODUCTS CO.

allurgist and in which great strides have been made during the past few years, is the science of metallography or the microscopic examination of metals. By means of this science the metallurgist is able to ascertain if the treatment he has given any metal in process of manufacture has achieved the desired results and imparted to the metal that structure which it must have if it is to meet the requisite physical tests. A microscopic examination of a piece of metal, steel or brass, will often give the metallurgist information which it might take days to find out by other means. Not only will it justify or condemn the accuracy of his treatment but it will often locate for him causes of failure or deterioration in metals which could never be detected by ordinary chemical or physical examination.

A case in point came up at the plant of the Dominion Bridge Co. a short time ago. Several furnace plates which were used in the construction of marine engine boilers, when heated and flanged, showed serious cracks and flaws in the steel. At first sight these defects looked as if they might be due to overheating or to red shortness in the steel due to a high sulphur content. A chemical analysis showed the sulphur to be low and a physical test cut from the portion of the steel adjacent to the cracks gave results well within the limits for a steel of that quality. A specimen that contained several cracks was then polished, etched and examined under the microscope. The structure of the steel was good and no signs of overheating were in evidence. Finally about 1-32 was filed off the face of the specimen and it was repolished. An examination then disclosed the cause of the failure. Embedded in the steel were particles of slag and all around the edges of the cracks broken up particles of slag could be seen, showing that these cracks had all taken place where the larger slag particles had originally existed in the steel. This is only one instance of the use of the microscope for the examination of metals.

Physical Testing and Miscellaneous Work

In the larger munition plants the metallurgist generally also performs the duties of a testing engineer. He carries out all the tensile, compression, bend and any other tests called for in the specifications for the finished product. A well equipped testing laboratory where physical tests can be made at a moment's notice will often save the manufacturer considerable money, especially at the beginning of a new industry when things are generally more or less in the experimental stage.

Other tests which the works chemist may be called upon to make include the testing of a coal or oil for calorific power or for some impurities such as sulphur, which might be detrimental to a certain melting or heating operation if present in excess. The testing and analysis of refractory materials of all kinds such as fire brick, clays, sands, and graphite also come within the scope of his work. The examination of quenching oils, cutting compounds, greases, scraps, and in fact any of the innumerable materials of this nature which enter into the various shop processes may also be a part of the chemist's daily work.

From this outline of the work of the chemist and the metallurgist in one of our large industrial plants engaged in the production of munitions it will be seen that he enters directly or indirectly into some stage or other of almost any of the finished products of the shop.

To sum up, the chemist and the metallurgist have played a prominent part in the development of the munitions industry in Canada and all signs point to the probability that in the future, when the industrial expansion will lie along more peaceful lines, the chemist will be able to still further widen the scope of his many activities.

FROM THE MEN WHO PRODUCE

Methods, Machining Devices, Systems and Suggestions From Shop And Drafting Room

Efficient Appliances for Economic Shell Production

BY J. H. RODGERS
Associate Editor Canadian Machinery

SUCCESSFUL munition production cannot be attained by concentraing on any one particular detail of manufacture but must be dependent upon the co-ordinate combination of every essential factor involved in the entire problem of shell making from the casting of the billet to the crating and shipping of the finished product. However, it will invariably be conceded that efficient equipment and shop facilities are probably the most important requirements for rapid, economic, and successful production. Apart from the well established effectiveness of the single purpise machine, the achievements of shell manufacturers are responsible, very largely, to the special appliances that have been developed for accomplishing certain operations in connection with this industry, and which have generally been designed to meet specific conditions. Varied experience on the part of plant superintendents, and their assistants, not forgetting the mechanics themselves, have been responsible for the many different devices constructed for performing identical operations. In certain instances shop atmosphere has been particularly accountable for the design of home-made equipment, as available material has very often been adapted to a purpose widely different from that for which it was primarily intended.

It is, therefore, not surprising to see the wide range of fixtures now in use in many of the large munition factories, and in almost every instance performing the work with the highest degree of satisfaction.

The following illustrations, with the accompanying descriptions, indicate a few of the large number of accessories that have been instrumental in the successful manufacture of the various shells, and likewise the maintenance of the different tools required for the work.

Determining a Basis for Machining Operations

Rough boring of the fuse hole in the nose of the shell is an operation in which much care is required to assure concentricity with the walls in the main portion of the forging. Owing to the slight variation in dimensions that are unavoidably created during the forging process, it is often very difficult to determine just the exact point from which machining should be based. While the piercing of a hot billet may, to the uninitiated, appear quite a simple operation, the production of uniform forgings is dependent upon so many different conditions that it is virtually impossible to find any two finished forgings exactly identical in every particular. Slight variation in the physical nature of the steel, uneven or irregular heating, presence of scale on the surface of the billet, careless placing in the dies, press out of alignment, etc., are some of the factors that decide the final quality of the product.

Generally, however, sufficient stock is available on all portions of the forgings to assure the production of the finished shell, at least respecting the specified dimensions; physical defects may arise from the same or other causes. The point therefore, is to select some place on the forging that will minimize the machining difficulties contingent on such irregularities. The superintendent of a plant that has had very good success on both the 8 inch and the 6 inch shells, has figured that a position on the profile about midway between the nose and the tangential point of the radius is the portion least subject to the discrepancies of the forging operations.

Invariably, the greatest wear on the forging punch will take place at the extreme nose or at the juncture of the lower taper and the long comparatively paralled section. Consequently, the neutral point will obviously be between these two positions; thus the reason for selecting the aforesaid point as a basis of operations. This method is adopted both for the initial centering and also the subsequent boring of the nose.

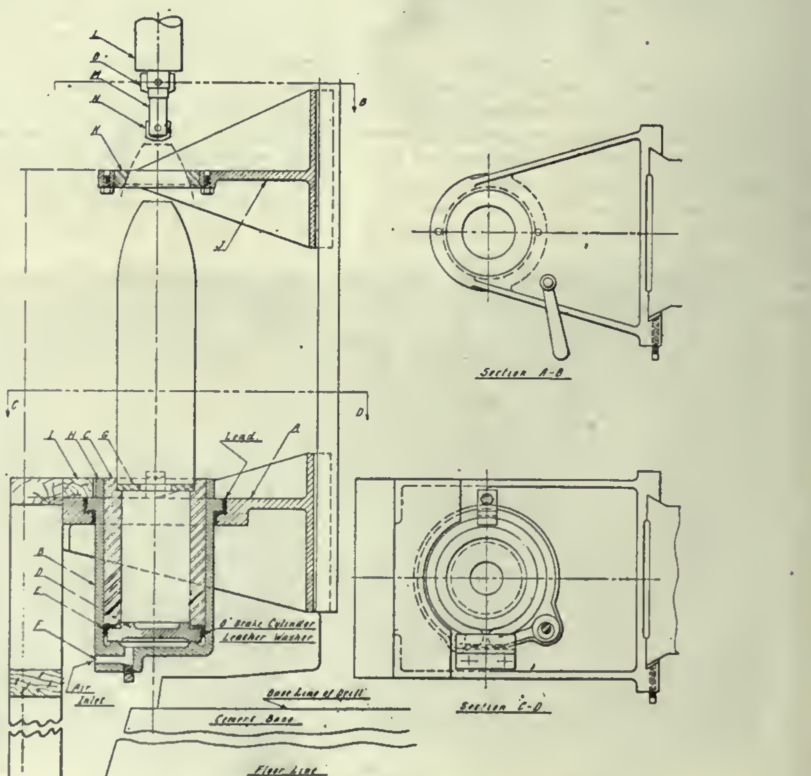

FIG. 1—FIXTURE FOR BORING AND CHAMFERING NOSE.

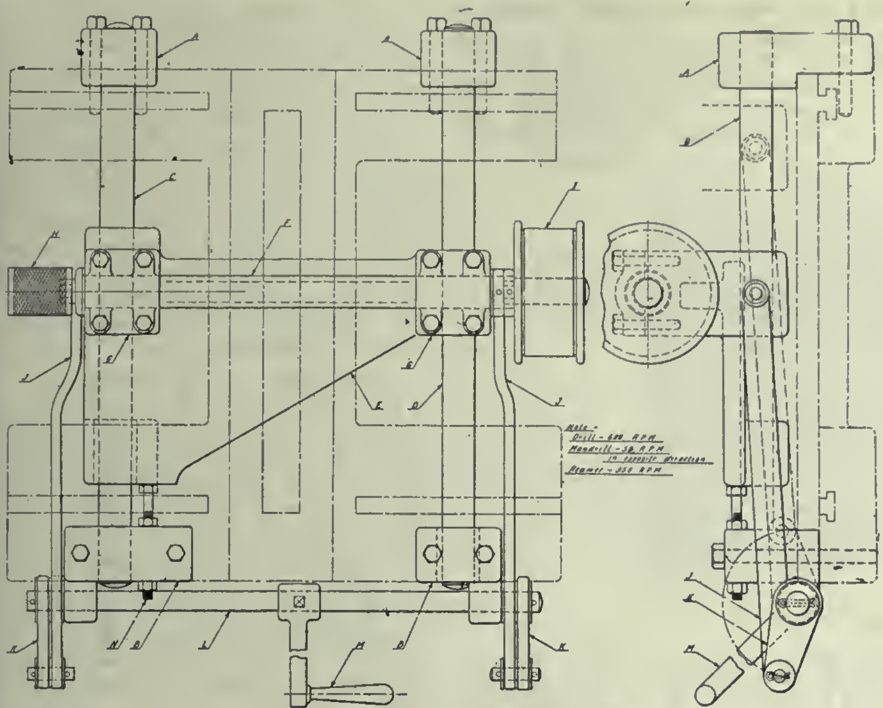

FIG. 2—CENTERING DEVICE.

Boring the Nose for Fuse Hole

In the sketch Fig. 1 is illustrated the device that has been devised for the boring of the nose on the 6 inch shells, after the outer portion has been machined. The attachment is applied to a Baker Drill, the main support for the shell being secured to the vertical slide of the main upright. Fitted to this casting is the cylinder B, in which the tubular plunger C is contained. To the bottom of this piston is fitted the head D and the ordinary air brake cylinder washer E; the inlet for the operating air is shown at F. A thin disc is fitted to the upper end of the plunger to support the base of the shell. Suitable wooden framework is provided on a level with the receiving and discharging runways to facilitate the handling of the shells. When the shell has been elevated to its working position the profile of the nose at the neutral point is forced into the receiving ring K which is held in position in the bracket J by means of the screws shown. For ordinary work, where the hole is comparatively even and not too small, the pressure of the air is sufficient to retain the shell in the proper position, but where excessive pressure is required in the drilling of the nose the shell can be additionally held by the action of a strap clamp H that is located on the upper end of the operating cylinder, and grips the plunger when the same has been forced upward. The roughing and the facing cutters are shown in position above the shell.

Importance of Initial Centering

A detail that is of vital importance in the ultimate success of the finished product, and one that has been often emphasized as an essential feature in connection with efficient production, is the initial centering of the shells prior to any of the following machining operations. Too much attention cannot be given to this simple but apparently insignificant detail. Upon the accuracy of the primary centering of the nose or the base, as the case may be, depends the final success or failure of the shell making process. Owing to the boring of the shell being the most difficult in the many operatios on the shell it is the recognized practice to work from the rough bore when a start is made on the gauging and drilling of the center from which the outer portion is to be turned. Common practice is to use expanding arbors for holding the forging while this centering is being performed. Generally the method adopted is to grip the inner walls on the parallel portion of the bore, but as stated above the better method is to select a neutral point on the inner profile where the irregularities are less likly to appear, or if so they are less pronounced. The chief feature in connection with centering devices is to have the mass rigid and as accurate as conditions will permit, and also to so design them that their operation will be as rapid as possible consistent with satisfactory work.

Special Centering Device

The devices that have been constructed for the efficient performance of this operation have been quite numerous and few plants have adopted the exact method for accomplishing the work, and it would probably be difficult to pick out any particular one that was more efficient than any of the others, each having their own pecularities and advantages. The one here illustrated has given very good satisfaction in the shop in which it is now used. The attachment is fitted to an ordinary engine lathe the spindle of which is equipped with a suitable extending arbor holding and revolving the shell. On the top of the traverse carriage is fitted the brackets A. A. and B. B., these brackets supporting the two cross slides C and D, which are lined in position by the pouring of babbit in one or other of the brackets when the complete fixture is in proper alignment. The main bearing casting E that carries the centering spindle F is fitted with three bearings to maintain alignment of the spindle. This is kept revolving continually and the center drill and the countersink are used alternately by changing in the small cam operated chuck H. The connecting rods J are attached to the lower portion of the cross slide and also to the operating shaft L by means of the short link K. By the movement of the handle M this toggle arrangement provides a rapid means for displacing the drill spindle out of a working position for the convenient placing and removing of the shell from the arbor. The positive stop N assures the exact alignment of the spindle when the same is returned to a working position. By running the arbor in the opposite direction to that of the drill spindle additional assurance is given to greater accuracy. In this case the work revolves at 50 R. P. M., the small drill at 600 R. P. M, and the reamer or countersink at 350 R. P. M.

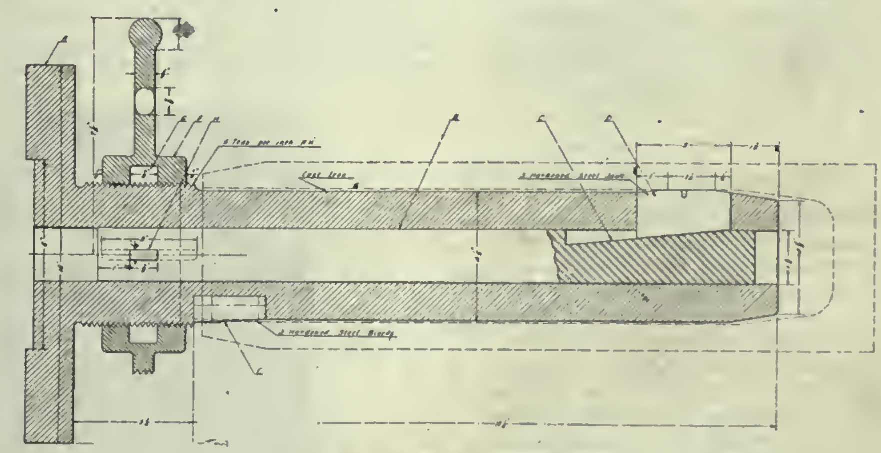

FIG. 3. RECENTERING ARBOR.

Centering Arbor

An arbor for recentering the shells after the boring has been completed is shown in Fig. 3. In this case the shell is centered at two points, at the open end and also at the section just adjoining the inner profile. The main portion of the arbor A, which is made of cast iron, is equipped with a large flange at the back end for bolting to the face plate of the lathe. Contained in the 1¾ inch hole through the center of this piece is the operating bar B, which has three equidistant tapered slots shaped in as shown at C, these being placed at an angle approximating 6 degrees. The gripping jaws D operated through slots cut in the outer end of the main arbor. These are collapsed by the action of the ordinary ring spring shown. For the centering of the open end the three hardened blocks E are fitted into the body of the arbor A. The handle for controlling the operation of the jaws is threaded to the rear end of the arbor, the position of the jaws being determined by the location of the said handle. The recess G in the handle is a close fit for the cross bar H which is a driving fit in the central operating rod. For screw operated arbors it is much better to have the control handle within easy reach of the operator, particularly where the actual machine work takes but a small portion of the total time.

Collet Chuck for 6-Inch Shells

Debate has often arisen as to whether the use of air operated chucking devices have any particular advantages over the hand operated type. When all things are considered, apart from the possible increase in the rapidity of operation, it is doubtful if the adoption of the air has any outstanding advantages over appliances operated by the hand method. The upkeep in both cases is often considerable but the initial outlay in respect to a complete installation of air generating equipment is frequently a subject not generally favored, by the small manufacturers in particular. An objectional feature that is often evident in the operation of screw chucks is the use of a sledge to free the jaws from the work after the handle has been released. To overcome this trouble one plant devised the simple attachment illustrated in the sketch Fig. 4. In many respects this chuck has similar features to those of other makes but the interesting point in connection with this particular one is the arrangement of the control at the rear of the lathe spindle.

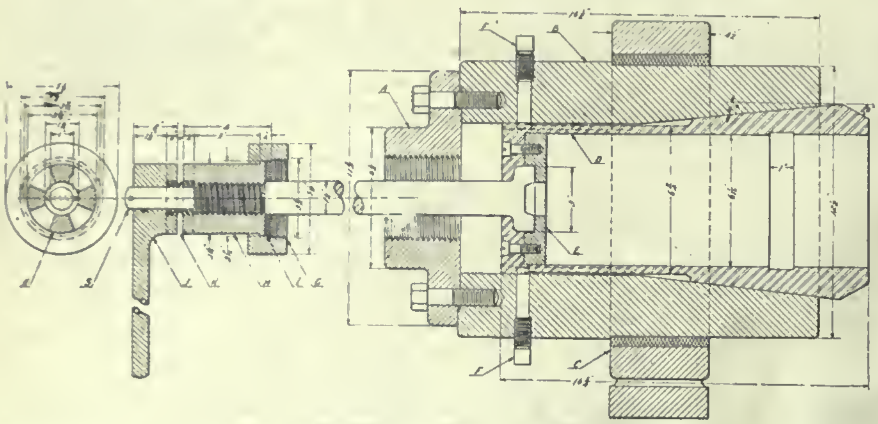

FIG. 4. ASSEMBLY OF COLLET CHUCK.

To the face plate A of the lathe is secured the main cylindrical portion of the collet chuck, the outer diameter running in the steady rest C for added rigidity. The split collet is provided with exceptionally long bearing on a taper of about 6 degrees with the axis of the lathe spindle. The inner end of the draw rod is fitted with a head that is located in a pocket formed by the tail of the collet and a special ring E, the latter having an opening in the center to allow the tit on the base of the shell to enter undisturbed. The screws F are fitted with hardened points which enter corresponding slots in the collet to prevent the same from turning under the action of the screw. Fitted to the rear end of the spindle is the collar G, which in turn supports the flanged bush H, a retaining bronze washer I being located between it and the end of the lathe spindle. The handle J, which rides free on the shaft S when the lathe is in operation, is fitted with a clutch face K, corresponding to that on the back end of the bush H, which is threaded to the draw rod S as indicated. To tighten or release the chuck the clutch K is used, and the action being positive in either direction, prevents the seizing of the collet jaws on the surface of the shell.

Expanding Driver

A simple expanding driver is shown in Fig. 4a. The steel container A is fitted to the spindle of the lathe, a recess being provided to take the inner end of the draw rod B, this recess adding to the rigidity and ease with which the screw may be operated. The hardened steel plug D is provided with three slots having a taper of 3 degrees with the axial line of the lathe spindle. The jaws E are the ordinary hardened type and may be serrated as shown for roughing operations.

Importance of Smooth Bores

Apart from the actual operation in connection with the machining of the shells, the upkeep of the tools is a detail that requires considerable attention to enable the work of munition making to be accomplished with maximum speed and economy. Successful production is dependent as much on efficient methods of tool maintenance as effective methods of machining operations. This is not only true in respect to some of the more important essentials but likewise to many incidental details that are very often put down as of minor significance. Probably few details are more important as having a vital bearing on successful shell production as the resultant work of boring cutters. In this particular it might be safe to say that more trouble has been occasioned than in all the others combined.

The importance of smooth bores entirely free from any irregularity of any kind has been emphasized ever since the inception of the shellmaking activity. The action of the shell in flight is such that dangerous consequences may result from even the slightest roughness or irregularity in the bore of the shell. To make this more clear, it must be understood that the charge contained in the high explosive shell is very susceptible to the action of the friction, so that the slightest scratch may form the basis of a premature explosion, an occurrence that must be guarded against by every means in the power of those responsible for the safekeeping of the men at the guns. The rifling action of the bore of the cannon has an instantaneous effect on the shell proper, and this revolving action cannot very well be immediately

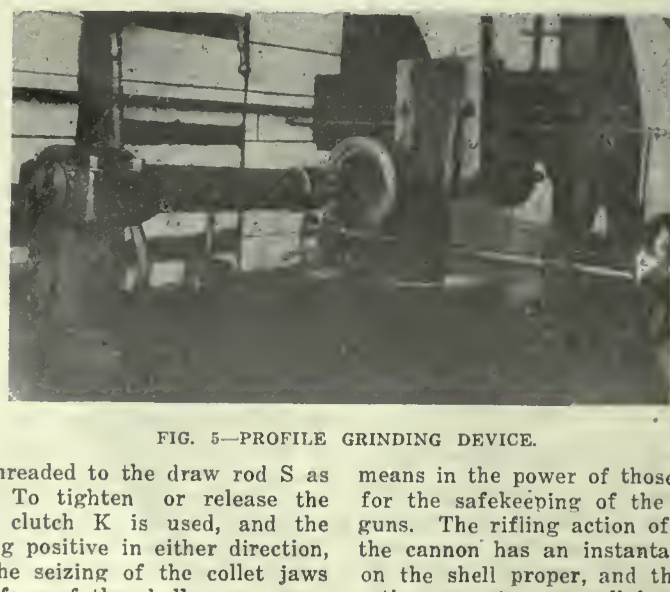

FIG. 5—PROFILE GRINDING DEVICE.

transferred to the inner explosive charge. The sudden centrifugal motion set up in the shell itself, when discharged, causes a relatively opposite motion on the inner charge; that is, the direction of motion of the shell and the charge are both the same but the speed of the former is much the greater, and until their motion becomes uniform, the possibility of premature explosion is ever present. For this reason it is imperative that every caution be taken to guard against such an eventuality, thus the care that is exercised in attaining a bore that will minimize, if not eliminate, the danger contingent to imperfect shells.

The smooth bore of the shell has been a feature in connection with shell production that has been given very much attention, but absolute perfection is next to impossible, as it may not be generally known that an exceptionally smooth bore may develop what appears to be physical defects that inexperienced inspectors may have difficulty in passing. This however, is a factor that might very well be overcome with a little instruction or enlightenment on the part of the inspectors. The essential consideration under known conditions is to produce a bore that will be as free from imperfections as present practice is capable of accomplishing.

Maintenance of Boring Cutters.

The maintenance and the accuracy of boring cutters are the prime factors in the production of work that will meet the strict requirements of shell specification. The numerous designs of boring bars and cutters that have been developed for this particular operation, together with many appliances constructed for the maintenance of the same, has clearly shown the efforts that have been made to overcome the difficulties incidental to maximum efficiency. The accuracy of the boring cutters, both as regards the shape and the dimensions, has invariably been left to the judgment and experience of the tool makers reserved for this purpose, the mechanical grinding of such tool to the proper contour not having been given much attention, owing to the difficulty of devising appliances to handle the work. Recently however, certain plants have constructed fixtures and other devices that have practically eliminated the possibility of inaccuracy resulting from the inability of the workmen to adapt themselves to this important detail. Such devices have not only aided in producing better work at less cost but have virtually removed the human element in the errors that might arise from faulty ground cutters.

FIG. 7—FACE GRINDING ATTACHMENT.

Interesting Grinding Fixture

One of these mechanical and almost automatic grinding fixturls is shown in Fig. 5. This cut shows the device as developed by the Montreal Tramways Co. for grinding the boring cutters for the 6-inch Mark XI. shell. The sketch Fig. 6 will illustrate more clearly the construction of the device. It was decided to utilize an old planer for the groundwork of this apparatus, owing to the unique advantages such a machine had for the operation and application of the parts. The main casting A, for supporting the boring arbor, is pivoted at the point B, by a pin which is secured to the table of the planer. The arbor D is held in position by the cap C, and is inclined at an angle with the axis of the grinding spindle, of about 6 degrees. The object of this is to alter the clearance on the cutting edge of the cutters. The inclination is such that with the tip of the bar in the circular direction, gives a variation of from about 7 degrees clearance at the nose of the cutter to a nil clearance at the extreme base of the cutter. This not only provides an ideal cutting angle for that portion of the cutter at which the bulk of the work is performed but also furnishes a non-cutting support and guide for that section of the cutter that has often, under other conditions, given no end of trouble. One of the difficulties that has frequently been experienced in the boring of the various shells has been the tendency of the cutter to gouge out a recess at the base of the shell, which could seldom be detected by the naked eye, but was quite evident under the examination of the inspectors with suitable instruments for the detection of such imperfections, the result being that many shells were rejected for this reason.

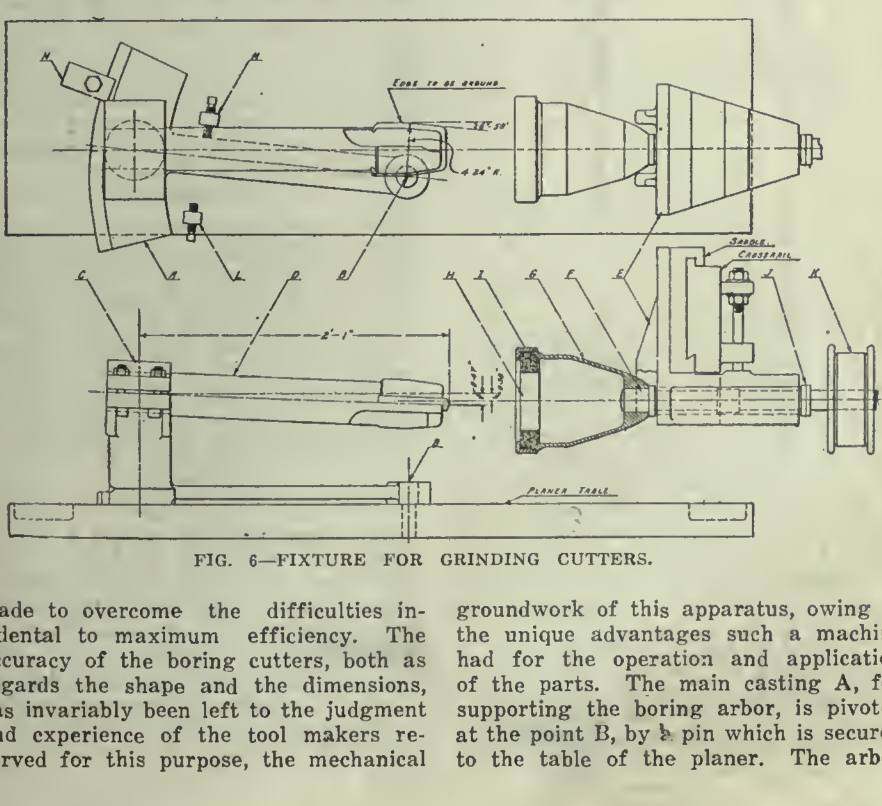

FIG. 6—FIXTURE FOR GRINDING CUTTERS.

Secured to the cross rail of the planer is a special casting that carries the grinding spindle F, to the nose of which is secured the wheel chuck G. It might be stated that this impromptu pot chuck is made from the upper portion of a spoiled shell, the walls having been lightened to facilitate the operation. The grinding wheel H is held in position by the large nut I. These wheels are made specially for this purpose, the diameter of the hole being such as to give the best results. Adjusting nuts J are provided on the rear of the grinding spindle to take up any lost motion in the shaft. Stops are located on the planer table to regulate the position of the bar when grinding the parallel and also the tapered portion. When grinding the straight sections the fixture is firmly clamped by means of the clamp N. The position of the pin B is so arranged that when the bar is being moved from one fixed position to the other the radius between the parallel and the tapered section, is automatically formed. After these cutters have been ground in this manner the only requirement is a slight application of the oil stone to remove any small burrs that have been formed. The longitudinal feeding arrangement is shown in the half tone cut Fig. 5.

Grinding Nose of Cutter

A somewhat similar device has been developed in the same shop for grinding the face and end radius of these same cutters. This is illustrated in Fig. 7, and a line drawing of the device is shown in Fig. 8. The foundation for this apparatus is a long piece of channel iron, upon which is secured an ordinary compound rest B, the upper portion C supporting the small angle iron D, to which in turn is bolted the small slide E that carries the electric grinder F. Lateral feed to the grinder is obtained by means of the small handle G. Also secured to the channel iron is the disc casting I, the central pin of which is located directly below the center of the nose radius of the cutter when the same is in a grinding position. Pivoted on the pin I, is the casting J, which, by the way, is a discarded trolley base; to this casting is secured the bracket K for retaining the bar M in position, an additional support being provided at N, in the shape of an adjustable Y support. A dust cap is provided to protect the bearing I from the dust of the wheel. As shown by the small end sketch, the bar is tipped in two directions so that when the fixture is swung around to grind the radius the clearance will correspond with that obtained on the preceding operation. Stops that are shown in Fig. 7 are provided to determine the exact position for either cutter.

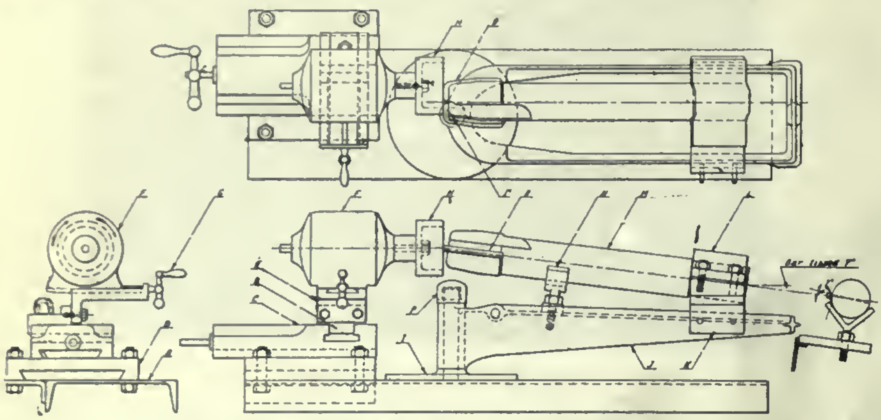

FIG. 8. GRINDING ENDS OF BORING CUTTERS.

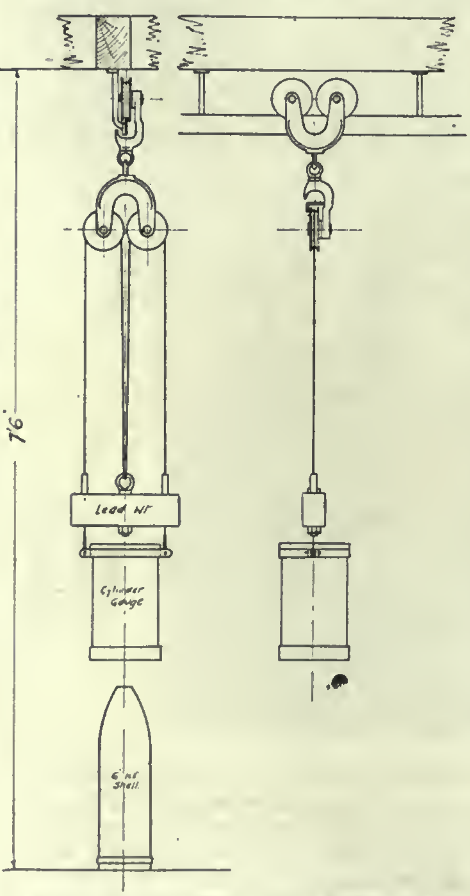
AN EFFECTIVE METHOD OF USING THE CYLINDER GAUGE ON 6-IN. H. E. SHELLS

By J. S. Downie

The cylinder gauge which is used for gauging concentricity of driving band with body of shell is often a very awkward one to use. It is heavy, weighing about 45 lbs., and if the band on the shell happens to be "high" in diameter or slightly eccentric, the gauge gets jambed down over the band and is often the occasion of considerable vexation and profanity before it is again got free. Unless properly suspended and balanced this gauge is apt to be the bugbear of any examination room and the "willing horse" generally gets the job of using it.

The method of using this gauge varies in different plants but it is usual to balance it in some way by means of a balance weight working through an overhead pulley. In small shops the gauge is generally suspended near to the weighing scales and each shell is gauged as it comes off the scales. This method is objectionable as it causes violent vibration in the vicinity of the scales and tends to make weighing inaccurate. It also necessitates the standing up of the shell immediately after coming off the scales which is a needless time and muscle absorbing operation. The most efficient method of using this gauge is by means of an overhead runway suspended immediately above where a line up of shells is to be examined on the bench.



METHOD OF HANDLING CYLINDER GAUGE.

The writer found the equipment shown on the accompany sketch answer the purpose admirably. The runway is formed of a special 'I' section of steel 2½ x ⅜ and can be bought in lengths suitable for any length of room and with the requisite fittings and equipment. The cylinder gauge is so arranged that it will hang from the runway and be free to run along a whole line-up of shells for the entire length of the room. The proper suspension of the balance weight is essential. A weight which is not properly hung or is not of the right form will frequently cause considerable bodily injury to the fingers or head of an unwary examiner.

The balance weight is of lead and is securely guided and held in place by the suspension wire rope and cannot injure the examiner or the surface of the gauge. The double runner which is a standard fitting, acts as a double sheave when inverted and linked together as shown. It also allows of the gauge being swivelled to any angle. This equipment has been found to answer all the purposes for which it was intended very satisfactorily.

Enlarging Business

The Cincinnati Iron and Steel Co. have changed their organization and are now known as the Cisco Machine Tool Co. The company have just lately erected a new building which gives them machine working space of two floors 64 x 230, this being exclusive of offices, warerooms, show rooms, shipping rooms and storage rooms which are in separate buildings. This building is equipped with all modern facilities, cranes, runways and every possible contrivance for the comfort of the workmen, while they have also installed considerable new machinery, including a 62 x 48 x 28 planer, a 3½ boring mill, 4-foot radial drill, two new milling machines, new keyseaters, arbor presses, upright drills and lathes, so as to increase production. The idea will be to double the number of men that are employed, and to keep up to its present quality the Cisco lathe.

ACID in oil will cause corrosion when in contact with moisture. The presence of sulphuric acid may be determined by a solution of barium chloride in distilled water, a few drops of which put into the oil after it has been thinned with an equal amount of gasoline or benzine will cause a whitish precipitate if acid is present. In the absence of moisture the acid is not so active and may escape notice.

A NEW polishing composition has been patented made of 8 oz. ceresin, 2 oz. beeswax, 2 oz. parafin, 6 oz. linseed oil, 28 oz. spirits of turpentine and 1 dram of carbolic acid. The first three ingredients are first mixed together and heated to the liquid form; the mixture is poured into the turpentine, the remaining constituents added, and the whole stirred until slightly cold.

The New Shell Has Brought Out New Methods in the Canadian Plants

Machining the 75-mm. in Modern Shop

BY A. G. WEBSTER
Associate Editor Canadian Machinery

THE 75 mm. shell being manufactured at the plant covered in this article is of the high explosive type, and a number of interesting methods have been devised for their production, some operations of course differing from those used for other types of shell.

The 75 mm. forgings, which are made in Canada have a minimum length of 11.825 in., a maximum diameter of 3.3 in., and weigh 22 lbs. The forging is very similar to the shrapnel, having the nose end open, but at the base there is a tit or boss. The shells have to be heat treated and the nose closed in as in the shrapnel shell. All forgings have a heat number stamped on the base and forgings bearing the same heat number are kept in a separate group. Each group is put through the various operations as a unit and a certain percentage is taken from each group for testing purposes. Each group is held until the results of the test have been made known when the remainder of the operations are proceeded with.

Cutting Off Open End

The first machining operation is cutting off the open end on cutting-off machines built by John Hall & Sons, Brantford, Ont. The shell is held in a universal chuck, the point to start the cut being determined by putting a gauge inside the bore, the outer end of gauge returning over the shell and the front cutting-off tool being placed in line with the end of gauge. There are two tools, front and back, mounted on the carriage, both feeding in and cutting simultaneously. When the end has been cut a beveled reamer at the end of a bar is inserted in the bore to remove burrs from the inside edge of hole. The cutting-off is only a roughing operation, the extra metal being removed when the nose is being machined after closing in.

Centering Base

After the open end has been cut off a center is drilled and countersunk in the tit on the base. In this operation the shell is held on an expanding mandrel while the combination drill and countersink is attached to a fixture on the bed of machine. The drill is fed forward by means of a hand lever. The buttons on the mandrel are drawn in before the shell is placed on it by means of a system of rods and levers operated by a foot lever. When the shell is placed on the mandrel the foot lever is released and the buttons forced outwards by springs, grip the bore of the shell. The rod operating the buttons on the mandrel passes through the head of the machine and is connected by rods and levers to the foot lever.

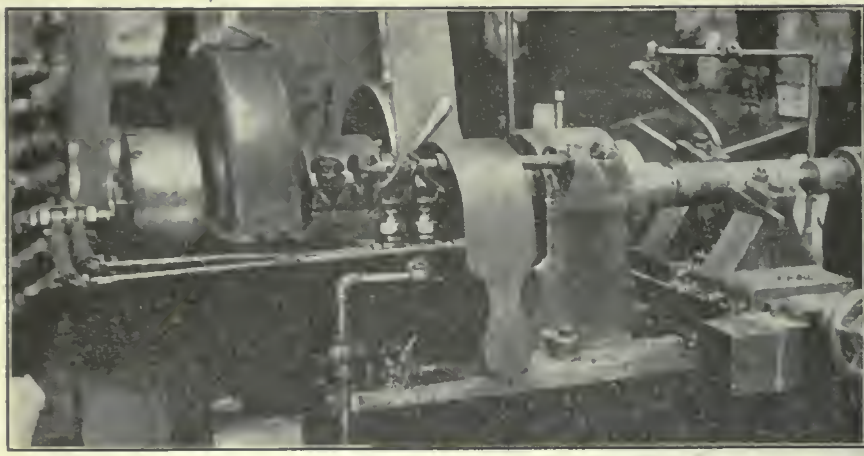
Rough Turning Body

The third operation consists of rough turning the body on a Bertram lathe equipped with an air chuck operating a short expanding mandrel for holding the open end of the shell while the base is supported by the tail center. The mandrel has two serrated buttons which are forced out by the action of the air chuck and grip the bore of the shell.

Two tool rests, back and front are mounted on the cross slide, the front tool makes the first and heavier cut, beginning at the base end, which is immediately followed by the back tool making a lighter cut. Both tools used are Stellite, and the cutting speed is 67 ft. per min.

Inside Boring

The next and fourth operation is rough and finish boring the inside of shell on a Bertram turret lathe. The lathe is equipped with a Manufacturer's Equipment Co.'s air chuck and a Bertram collet chuck for holding the shell. There are three tools held in the turret which are employed in the following sequence. The first tool is a bar with a forming cutter at the end for roughing the base inside. The second tool is a boring bar for roughing the inside contour of shell. This bar has also small cutter at its base for rough facing up the nose. The third boring bar has a similar cutter for finishing the contour and also a forming cutter for finishing the base inside. This bar has also a small cutter at its base for finishing the face of nose. The finishing cut is made at a slower speed than the first two. All three bars have a small hole drilled the entire length to convey the cutting lu-



ROUGH AND FINISH BORING OPERATIONS.

bricant to the tip to wash away the chips as well as lubricate the cutter. A flexible tube is attached to the base of each boring bar, connecting it with the lubricant supply tank.

Grinding Bore

A minor operation is performed at this stage to clean up the base inside. This is a grinding or buffing operation. The machine has a horizontal spindle at the end of which is a grinding wheel of special shape. While the spindle is being revolved the shell is held up to the wheel and the base inside finished.

Cut Off Base

The next operation is cutting off the base on John Hall & Sons cutting-off machines equipped with air and collet chucks. There is a bar stop inside the head to locate the shell in the correct position. The machine has two tools, back and front, both cutting simultaneausly. This operation removes the tit which has carried the countersunk centre.

Re-Turning Outside Body

The seventh operation consists of returning the outside of shell to make the outside concentric with the bore of shell. This operation is performed on C.M.C. lathe equipped with a Manufacturers' Equipment Co.'s air chuck and an expanding mandrel. The mandrel has four serrated buttons for gripping the bore of shell. The machine has two tools, back and front, which take one light cut the entire length of the shell and then another cut from the base up, for about 2 inches.

Finish Base Thickness

The next operation, the eighth, is to bring the base to the required thickness. Before the shell is put on the lathe it is gauged to ascertain how much metal has to be removed to bring the base to the required thickness. The gauge used for this purpose consists of two parallel rods connected at one end by a swinging arm. One rod is put in the shell until it bottoms and the other has two feet which rest on the shell body while at the end it has a centre punch for marking where the shell has to be cut off at the base.

A C. M. C. lathe equipped with an air chuck and Bertram collet chuck is used for facing the base. There is a stop in the collet chuck to locate the shell in the correct position. Usually a light cut is all that is necessary to make the base the required thickness. The shell is then gauged again to see if the proper amount of metal has been cut off. The base is left on the "high" side after being machined. At this stage the shells are carefully gauged and the bore examined by inspectors to catch any imperfections before the shells are taken to the heat-treating department where the nose is closed in and the shells heat treated. This is the first government inspection.

Closing In Nose

This heat-treating department contains a furnace and press for the nose operation and two continuous furnaces for the heat treatment. The furnace for the nosing operations will heat nine shells at a time. It is fired with oil fuel. The press is a rebuilt Bertram power-driven punching machine with the dies bolted to a plate attached to the ram. The seat for the shell base is fixed to the table which is stationary. The seat is so designed that the shell can be slid into it; thus requiring less head room when lifting the shell in and out. The press is located quite near the furnace so that the operator can take the shell from the furnace and place it in the press at one motion. The ram is released by a foot lever when the shell is in position.

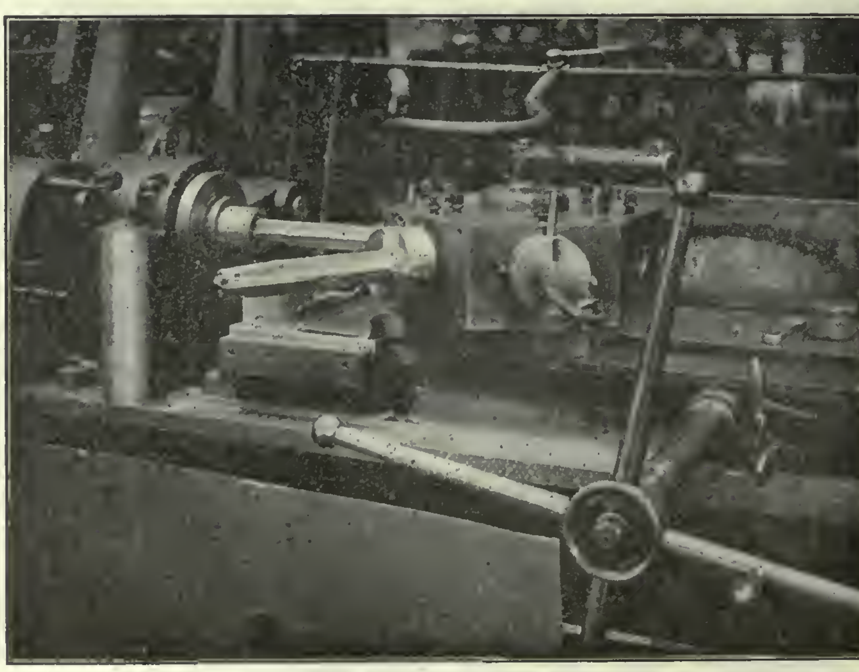
Heat Treatment

The hardening and tempering furnaces are both of the continuous type and are the same design and size. This type of furnace has two oil burners at each end, one at each side near the bottom. The hearth of the furnace is inclined so that the shells when fed in at the back can roll down gradually towards the front end. The rolling motion is assisted by a pusher at the back which is located just outside the furnace and at the point where the shells are fed into the furnace. The pusher has a reciprocating motion and is operated by a pulley through a belt from the line shaft. Two rows of shells are fed through the furnace giving a production of about one thousand in a twelve-hour shift.

The hardening furnace is maintained at a temperature of 1,550 degrees Fahr., and it takes each shell about 38 minutes to pass through. After being heated the shells are quenched in an oil bath and then passed on to the tempering furnace. The oil is cooled by pumping it to a tank outside and then back again to the quenching tank. The temperature in the tempering furnace is around 1,100 to 1,150 degrees Fahr. and the time occupied is the same, viz., 38 minutes. The shells are cooled off gradually after being in the tempering furnace. Hoskins thermo-electric pyrometers are installed for controlling the temperature in these two furnaces and also indicating and recording instruments.

Brinell and Tensile Tests

At this stage of manufacture it is necessary to prove that the shells possess



ROUGH TURNING, OUTSIDE BODY.

FURNACE AND PRESS FOR CLOSING IN OPEN END AND FORMING NOSE.

the required degree of hardness. It is essential that the physical properties of the shell should be within certain well defined limits which are obtained by the heat treatment. There is a Brinell test, which corresponds to the schleroscope test, and also a tensile test. There is also a hydraulic test which will be referred to later.

For the Brinell test, ten per cent. of the shells are tested, which is equivalent to 50 out of each group of 500. In this method each shell to be tested is placed on an Olsen testing machine. A flat spot is first ground on the shell body when it is placed on a V block which is so adjusted that the pressure will always come in a radial line with the axis of the shell. A hard steel ball is then pressed into the shell making an indentation 10 mm. across under a pressure of 6,600 lbs. The readings which are taken through a microscope should give between 3.9 and 4.5 mm. The pressure is applied for 15 seconds, but as slight variation in the dimensions of the indent may arise from unequal length of time of applied pressure, it is desirable to check the period of time accurately.

For the tensile test, one out of every thousand shells is selected and two test pieces cut out on a milling machine. The test pieces are machined to the required shape and sent to a government laboratory for the tensile test, each group of shells is held up until the result of the test is known.

Boring Nose and Recess

After the shells have been heat treated and tests have proven satisfactory they are taken over to have the nose finished off. This is done on a number of turret lathes built by the Davis Machine Tool Co, Rochester, N.Y. All these machines have air and collet chuck equipments for holding the shell. The turret holds five tools, the first consisting of a stop which bottoms in the bore and a double end cutter for facing up the nose end. The second tool rough bores the nose and recess. A reamer is then passed through the nose, finishing the part that will be threaded, while the fourth tool finishes the recess behind. The fifth tool faces off the end of nose to length.

Threading Nose

The nose-threading operation is done on a Bertram turret lathe, the turret being equipped with two Murchey collapsible taps. The lathes have air and collet chuck equipment. Two collapsible taps are used for this work, it has been found that better results were obtained than by using one tap only. The strain on the taps is diminished and more accurate threads are formed.

Finish Turning Body

A number of C. M. C. lathes are used for this operation which consists of finish turning the nose profile and body as far as the copper band. These lathes are also equipped with air chucks and collet chucks for holding the base of shell. The screwed centre which has been inserted in the nose is carried on the tail centre.

Th forming cam which is situated under the work has a spring for holding the roller on the cross slide up to the cam, thus forming the correct profile. A light cut only is taken at this operation.

Grinding the Bourrelet

A special operation is necessary for finishing the bourrelet as there are practically no limits to the size, and it also must be very smooth. The bourrelet is finished on a Ford-Smith grinding machine, equipped with air and collet chucks. The screwed centre is retained in the nose and carried on the tail centre.

Facing Base

Two or three short operations now follow. The first is facing the base and the second is finishing that part of the body near the base not machined when the body was finished. Both operations are performed on C. M. C. lathes equipped with air and collet chucks, and a light cut is taken with an ordinary turning tool.

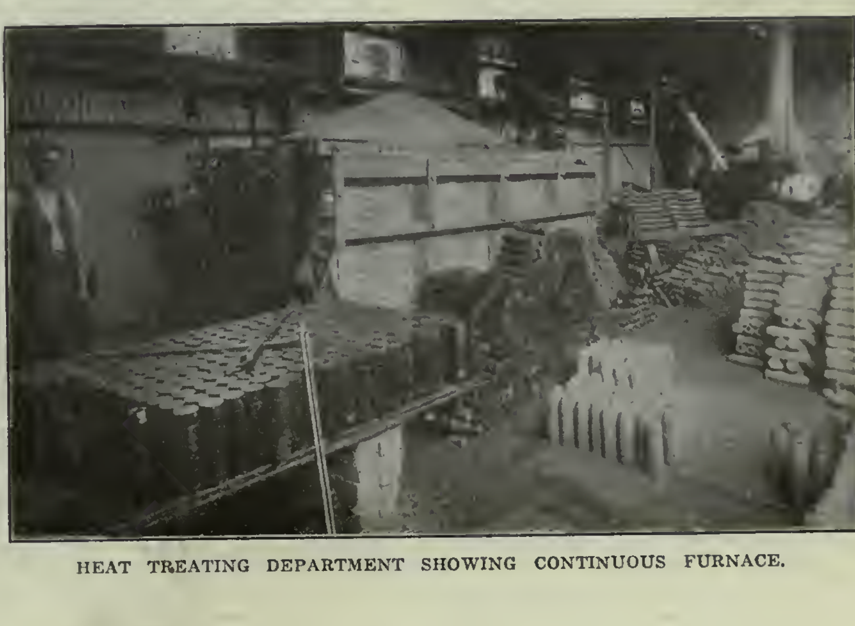
Copper Band Recess

The recess for the copper band for the 75 mm. shells differs from the shrapnel in that it is knurled instead of having waved ribs. The purpose, of course, is the same, to prevent the copper band from moving round. The machine for this work has the standard air and collet chucks.

The tools are mounted on the cross slide, back and front, with a drop down stop between them. The stop is for the purpose of adjusting the shell in the correct position. The front cutter which forms the groove is used, first by being fed up to the work, when the groove has been formed the back tool is brought into play and a straight rib formed.

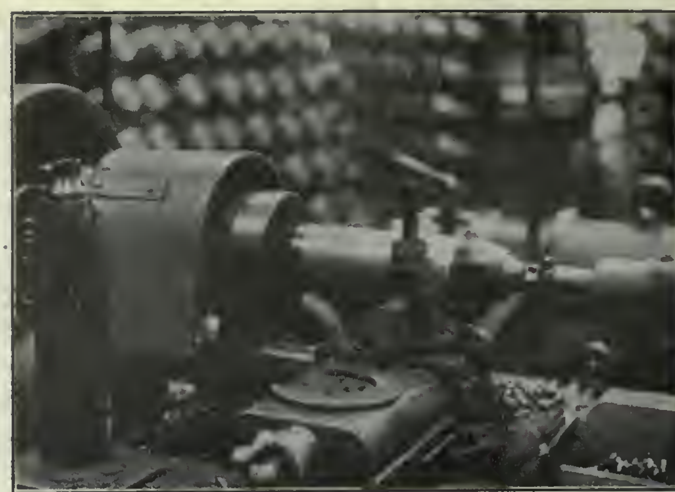
Knurling

The shells are then taken over to a machine nearby to be knurled. The knurling machine consists of a cradle with four smooth rollers for carrying the shell in a horizontal position. A lever forces the cradle, and with it the shell,



HEAT TREATING DEPARTMENT SHOWING CONTINUOUS FURNACE.

FINAL INSPECTION.



FINISH TURN, BODY AND PROFILE.

up, bringing the groove in contact with the knurl. The knurl is fixed on a horizontal spindle and is driven by a pulley from the line shaft. While the knurl revolves, the groove is pressed up against it, thus forming the knurl in the groove.

Chamfering

The end of the shell body at the base is chamfered to take the cartridge case and a chamfer is also formed near the copper band groove, on the base side. The angle of chamfer in the first case is 9 degrees and in the second 4 degrees.

The machine is equipped in a similar manner to that used for forming the groove as described above, except that the tooling is slightly different. One tool holder is mounted on the cross slide with two chamfering tools. Between them is a roller which engages with the shell body and allows the cutters to work concentrically.

Base Cover Groove

The 75 mm. shell has a brass base cover to protect it from the corrosive action of the explosive. A circular groove is formed in the base in which this cover is secured. A Bertram lathe with air and collet chuck equipment is used for this operation.

The tooling arrangement which was designed specially for the work consists of a fixture containing two tools. The first tool roughs the groove and is fed up to a stop. The second tool which is operated by a lever and has been moved away from the work is then fed forwards towards the shell base and forms the undercut. This tool slides forward at an angle to form the undercut.

Hydraulic Test

The next operation is the internal hydraulic test done in a Metalwood hydraulic testing machine. There are two of these machines each having a capacity ranging from 1.200 to 1,500 shells per day. The shell is first filled with water, or sealed, in the tank and placed nose down in the press. A pressure of 10,000 lbs. per sq. inch is applied inside the shell. This test is made in order to detect by excessive expansion any defects such as leakage or defective and porous material, as well as heat cracks, resulting from improper heat treatment. The permanent expansion of any shell over .003 will cause rejection. The pressure is applied for 15 seconds and the expansion readings are taken at a point about ½ in. below the bourrelet.

The extension of the shell body is measured while the pressure is being applied. The measuring device consists of a clamp which grips the shell body and also carries an indicator. When the shell expands outwards under pressure the indicator shows the amount of extension. Ten per cent. of each group of shells are subjected to this test.

Cleaning and Sand Blast

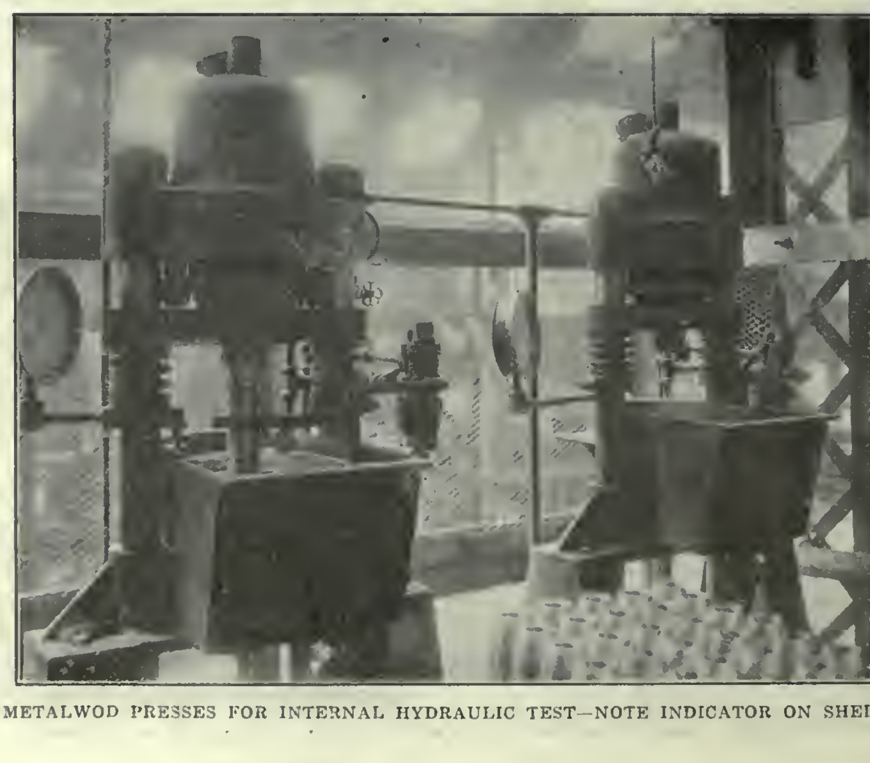
A series of less important operations now follow, the first being sizing the nose threads which is done with hand taps. The shells are then washed in hot soda water to remove grease and dirt, etc., and then taken to the sand or shot blast. This operation, which removes tool marks and scale from the shell is done on two machines supplied by the Gray Mfg. Co., Toronto. The shell is held nose down in a fixture which is revolved slowly, while shot drawn into the air line is injected into the shell bore.

Nicking the nose is the next operation, being performed on a bench miller. The shell is clamped in a horizontal position on a fixture on the table of the machine, then a small slot or nick is milled in the nose. The shells at this stage are carefully examined, gauged and weighed, etc. This is the second government inspection.

Copper Band Operations

The shells are now ready for the copper band. The band is pressed into the groove, cold, on an hydraulic wheelpress rebuilt for this particular service.

The copper band is turned on a Symington machine equipped with air and collet chucks. A stop in centre of chuck fixes the correct position of the shell. The shell nose is carried on a



METALWOD PRESSES FOR INTERNAL HYDRAULIC TEST—NOTE INDICATOR ON SHELL.

TRUCKS USED FOR CONVEYING SHELLS BETWEEN THE VARIOUS OPERATIONS.

cup centre on tailstock centre.

The forming tool is at the back on the cross slide, while at the front is a tool rest used for hand turning when trimming the band.

Pressing Base Cover

At this operation the base is finished. A lead disc with the brass cover is laid on the base of shell and the cover rolled into the groove, machined out at an earlier operation. The base cover is pressed on in a drill, the spindle being equipped with a special device containing three hard steel balls. The shell is held in a box vise on the drill table while the base cover is being rolled. The rolling expands the brass cover, forcing it into the groove. The middle of the cover is pressed down against the base during the operation by a spring stop in centre of rolling fixture.

The flat lead disc is 2.2 in. diameter and .03 in., thick. The brass base cover which is slightly cupped, is 2.56 in. dia., and .02 in. thick.

The body of the shell is now marked with the firm's initials and the lot number. The machine used for this operation is a Bertram marking machine.

Shot Blast and Wash

The shells are again cleaned in a Gray shot blast machine, the same type as described in a previous operation. The shells are then washed in hot solution of borax and water and rinsed with cold water by means of a bubbler. The shells are afterwards laid on a bench and dried with compressed air.

Varnish and Lacquer

The shells are coated inside with a thin layer of shellac varnish to protect the steel from the corrosive action of the explosive. The shell is varnished while rotating on belt-driven rollers let into the table. The varnish is sprayed in by an Eclipse air-brush after which the varnish is air dried. A brass bushing is placed over the threads in the nose before the varnish is sprayed in.

A coat of blue lacquer is applied to the shells, lacquer being used instead of paint. This operation is done on a Canadian Fairbanks-Morse painting machine which enables six shells to be lacquered at a time. The machine has six stands for the shells, the stands being rotated slowly by an endless chain drive. A wheel upon which the stands are mounted is rotated by hand. The wheel is mounted on ball bearings and requires very little effort to turn it round as each shell is finished. The varnish and lacquer were supplied by Lowe Bros., Toronto.

Final Operations

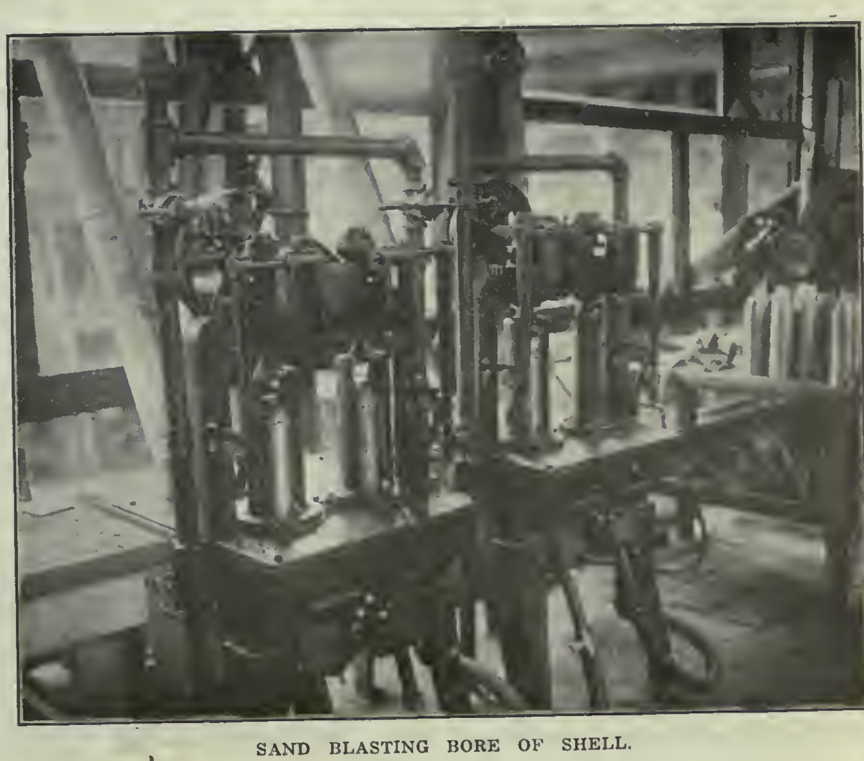
A wooden plug is screwed into the nose after the threads have been greased with vaseline. The shells are then packed nine in a box and shipped.

Final Inspection

The final government inspection is made after the varnishing operation. All shells are carefully examined, weighed and gauged before shipment. The mean weight of a 75 mm. shell finished without the fuse, is 9½ lbs. with 9 ozs., tolerance between the high and low limits. All shells are gauged after each operation.

The air chucks referred to above were supplied by the Manufacturers Co., Chicago, and the collet chucks by John Bertram & Sons, Ltd., Dundas, Ont. The shells are moved from one operation to another by means of trucks holding 112 shells each. The trucks were supplied by the Lansing Co., Lansing, Mich., and also by John Watson Mfg. Co., Ayr, Ont.

Electrical Fittings, Engineering Plants and Accessories, Metal Works, Etc.—A well known English manufacturing firm wish to get into touch with good Canadian houses willing to act as their agents for definite territories in the following lines: Electrical light fittings, engine details for automobiles, aeros and marine work, machined parts, sheet and tube metalwork, architectural and art metalwork, wrought ironwork, engineering plants for electrical power, pumping and other purposes, heating, ventilating and cooking plants and accessories, automobiles, etc. (Address British Trade Commissioner in Canada, 367 Beaver Hal' Square, Montreal, referring to British Trade Inquiry No. 3003.)



SAND BLASTING BORE OF SHELL.

OPTICS AND MECHANISM

By A. L. Haas

The matter of precision and the ability to work to fine limits is intimately bound up with the means open for exaggeration and multiplication of error. Indeed, fine work is only possible by extending the range of normal vision to detect the infinitesimal. Magnification steps in to the aid of the limited human senses of touch and sight and large scale reproduction is the only means open for comparison of small differences. Whitworth relied upon touch, or as the mechanic terms it, feel, and when he utilized a gravity piece to render difference in feel immaterial, he referred the matter of exact size to the impartial pull of the earth's mass.

Vision Extension

Mostly, however, precision is a matter of vision extension; although the old-time mechanic by trained touch obtained exact duplication within very small limits, and so obtained comparative size, he was for want of vision unable to determine end length.

The sense of vision has a very limited range with any certainty, perception stops long before the minute differences which are of mechanical importance are reached; hence extraneous aid must be given that these are appreciated and more especially determined.

All recent precision advance has been done by the application of optics to determine inexactitudes. A beam of light is the straightest thing known or imaginable and magnification originating in astronomy and microscope has received vast study from mathemetician and scientist. At present the field of optics as applied to the mechanical industry is perhaps the most fascinating of all the engineering combinations yet effected.

The Engineer's Position

One remarkable thing about the engineer is that he occupies the centre position in the web of science. He makes contact with the fringes of almost all material activity and takes and leaves at pleasure all the discoveries made in other quarters; and because such is his mission, wrests them to ends of direct practical utility.

This peculiar position has led to some hybrid activities. There are chemists with very fair mechanical knowledge, engineers versed in chemistry, chemical engineers who design and install the apparatus for chemical manufacture on a large scale.

There is also the side of materials; the specialist chemist who is termed metallurgist is often remarkable for his mechanical skill, while most engineers have at least a nodding acquaintance with metallurgy.

A Rare Combination

The combination of engineering and optics is rather rare, yet the mechanical expert with a mathematical turn will find in the subject of optics not merely an interesting hobby but one directly applicable to the problems of precision. Optical apparatus is the province of the instrument maker from whose ranks sprang James Watt, the patron saint of the engineer.

The marriage of mechanism with optics should give the mechanical industry,—indeed has already, and is still giving it—apparatus whose refinement magnifies error and determines infinitesimal size. It is a most promising field certain to afford considerable expansion in the near future. A beam of light is an exact straight line, a perfect mirror is a plane surface, angles can be determined by stellar observations and all easily determined and checked to an accuracy undreamed of in mechanical practice.

A Question of Apparatus

The sextant, level and theodolite need reapprehension in an infra-sense into the realm of the machine shop and while the problems and apparatus involved are complex, they are yielding to patient treatment. One thing certain is that the basis of mathematics as it concerns optics is already a well worked field so that it is more the practical determination by suitable apparatus which is in question.

The dial indicator, the micrometer, the measuring machine enlarged vision and determined fine errors; optical means may be expected to magnify such determination a hundredfold, making such determination more absolute pro rata.

The work of the N.P.L. in this realm deserves nothing but unstinted praise, and a large extension to engineering optics will be of the greatest value to the industry at large and the greater perfection of its product.

ACID RESISTING IRONS

By V. R. O.

The chief acid-resisting irons are silicon alloys, containing up to 15 per cent. of silicon. They are known under different trade names, such as Tantiron, Ironac, Duriron, etc. They are characterized by extreme hardness, which renders it impossible to machine them. Apparatus involving their use should be of simple form, and should not require any machining, except perhaps, facing by grinding. Their tensile strength is low, and they should not be subjected to high pressures. They are brittle, and a 4 per cent. silicon-iron shows a cubical crystal surface when fractured. There is considerable difficulty in casting to avoid soft patches. The effective life of a concentrated nitric acid pump may be as long as six months. The metal takes a very high polish and does not rust. Thick castings cannot be produced as internal stresses cause fracture.

The following are typical analyses of (1) Duriron and (2) Tantiron:

		Per cent.
(1)	Silicon	14 to 14.5
	Manganese	0.25 to 0.35
	Total carbon	0.20 to 0.60
	Phosphorus	0.05 to 0.10
	Sulphur	under 0.05

Melting point 2,550 deg. Fah. Sp. gr. 7.0. Compression strength 70,000 lb. per square inch Tensile strength 25 per cent. less than cast iron.

		Per cent.
(2)	Silicon	14 to 15.
	Sulphur	0.05 to 0.15
	Phosphorus	0.05 to 0.10
	Manganese	2.0 to 2.6
	Carbon (graphit)	0.75 to 1.25

Melting point about 2,550 deg. Fah. Sp. gr. 6.8. Tensile strength 6 to 7 tons per square inch.

C.P.R. DISPLAYS RESOURCES OF CANADA

Visualizing in a striking manner a large number of the diverse natural resources of Canada, the C. P. R. has just opened to the public an exhibit at the Windsor street station, Montreal. This exhibit, which is situated in a room immediately adjoining the main entrance to the station on Osborne street, has been prepared by the collaboration of the Quebec Government and the C.P.R.

One half comprises the Quebec exhibit, consisting of samples of the resources of the province—lumber, asbestos, and other minerals, grain, maple sugar, furbearing animals, such as the ermine, marten, mink, fox and beaver, and fish and game birds.

The C.P.R. exhibit has been gathered from the entire Dominion. A splendid display of grains produced in the fertile fields of Western Canada is a special feature. Supplementing this is a big collection of fruits, forestry products and minerals. A number of colored transparencies show the methods used in developing the forest resources of Canada, from the primary state to the finished product, such as wooden ships. Other transparencies illustrate some of the summer resorts along the company's lines. Complete and recent statistics of all the country's resources add conviction to the display. The exhibit is installed in handsome showcases, brilliantly lit; and it is interesting to know that all the material used in the construction room is Canadian material exclusively.

RESEARCH DIVIDENDS

The great laboratory of the General Electric Company at Schenectady is maintained at an annual cost of over $500,000 and employs seventy-five investigators, including among them several who are eminent in the world of pure science. One of the products is the tungsten lamp which is now manufactured by twenty-two factories scattered over the country. This lamp, according to a very careful estimate made in 1911, was, at that time, effecting a power saving valued at $240,000,000 per annum. Since then the consumption of this type of lamp has increased threefold and further research has increased its efficiency of light production nearly 25 per cent. The research workers are discouraged from thinking of financial results, as discoveries are more likely to be made by those who are working in the scientific spirit.

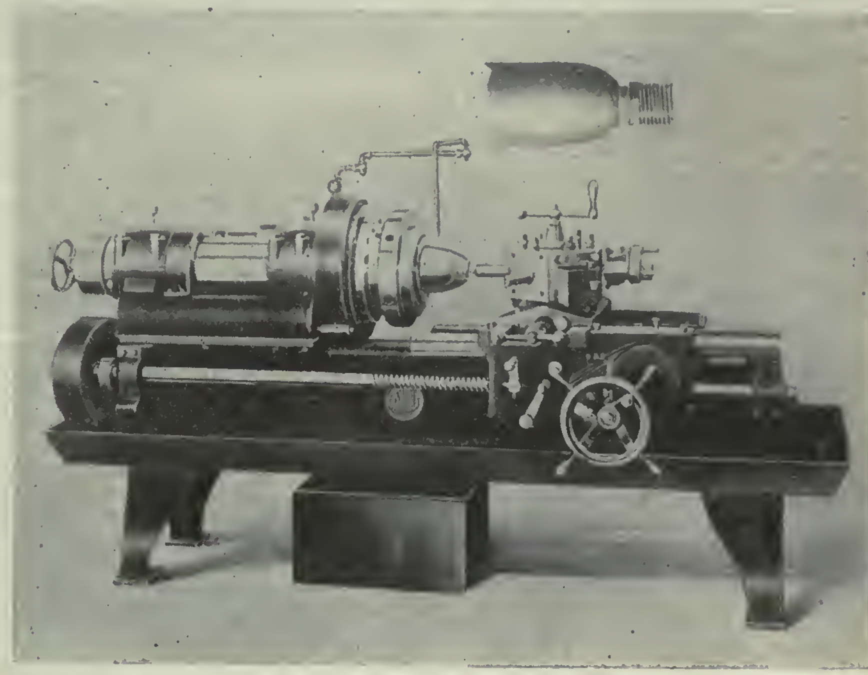
DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

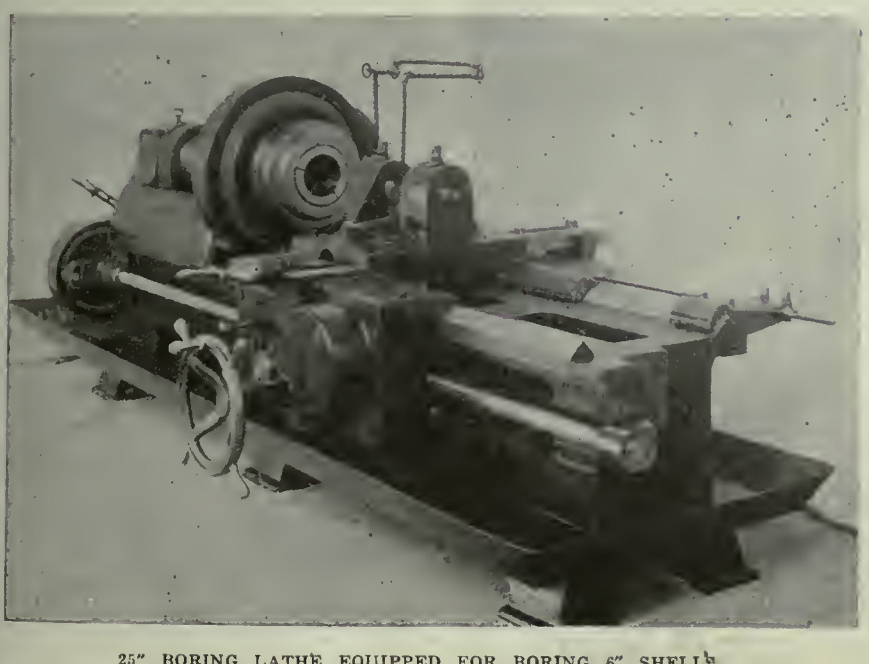
SPECIAL BORING LATHE IN VARIED MODELS

SHOWN in the accompanying illustrations are two of the several types of special lathes developed for shell work by the Gisholt Machine Company, Madison, Wis. Many of these machines have been built for shell work and are now installed and operating in munition plants in England, France and Italy. At the present time several lots are going through the factory and are destined for American shell shops, some being of the 25-in., and others of the 16-in. machine, both of which are shown. Though designed for shell work they are adaptable for other purposes. The 25-in. machine illustrated is one of an installation to be used in boring 6-in. or 155 mm. shells.

In one of the accompanying illustrations is shown a sketch of the 155 mm. U. S. howitzer shrapnel, and also one of the 155 mm. U. S. high-explosive shell. The letters A. B and C in the case of the shrapnel and A, B, C and D in the case of the high-explosive shell indicate the finished surfaces on the inside of both shells which can be advantageously handled on the new lathe, using either a single point cutter in the boring bar with a former block on the taper attachment, or boring heads located on the boring bar, and with the cross-slide carriage set central. The taper attachment is shown on the back of the machine.

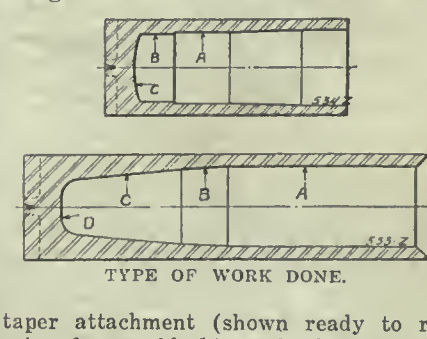


16" SIMPLIFIED LATHE EQUIPPED WITH COLLET CHUCK AND TOOLS FOR BORING AND THREADING NOSE END OF SHELLS UP TO 155-MM.



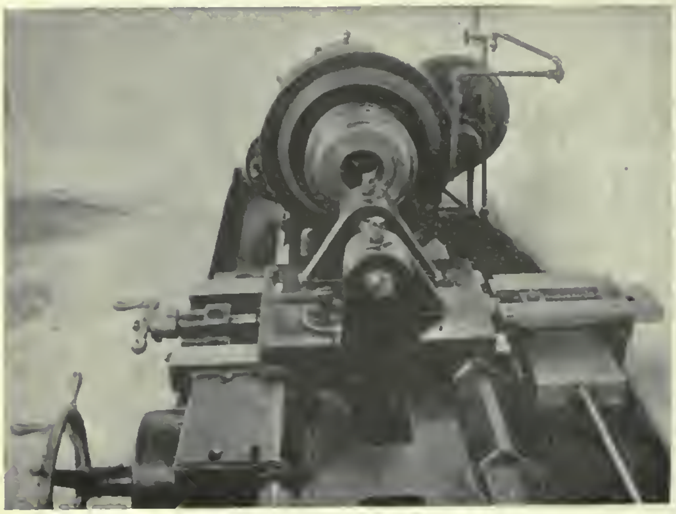
25" BORING LATHE EQUIPPED FOR BORING 6" SHELLS.

Notable in the machine is the rigid design and massive construction of the



TYPE OF WORK DONE.

taper attachment (shown ready to receive former block), and of the cross-slide carriage which is shown ready for the boring bar. In the machine illustrated the cross-slide carriage is bored to 3 inches in diameter, although the diameter may be made to vary with the



25" BORING LATHE EQUIPPED FOR STRAIGHT BORING OPERATIONS OR WITH BORING HEADS.

requirements. Also to be noted is that the cross-slide carriage bears the entire width of the slide, which is 18 in. wide and 24 in. long.

The 25-in. machines are made in several models, some carrying turrets, others simple tool posts, etc. They may be built with collet chucks as shown, or with 24-in. three-jaw scroll chucks, or four-jaw independent chucks as may be deemed best to handle the required work. The 16-in. lathes have a 3¾-in. and 6¼-in. spindle bore while all the 25-in. machines have a 6¼-in. spindle bore. The several models make possible combinations of chucks and carriage equipment adaptable for a wide range of work in general manufacturing as well as in the production of shells.

26-INCH SHELL BORING LATHE

The accompanying line drawing illustrates a recently designed lathe specially adapted for shell work. The bed is of particularly heavy construction, 24 inches wide, 18 inches deep, with an overall length of 10 feet, 6 inches. The head stock is made very rigid and is fitted with extra large bearings, the front being 15 inches in diameter and 12 inches long, and the rear bearing 6 inches diameter with a length of 10 inches. The spindle is fitted with an air-operated collet chuck, the pneumatic cylinder being located at the rear of the spindle. The power drive is very effective, the main pulley being 20 nch belt. Motion is transmitted by a train of heavy cut gears, the first pair having a face of 3½ inches of 4 d.p. and the second pair 4-inch face with a 4 d. p.

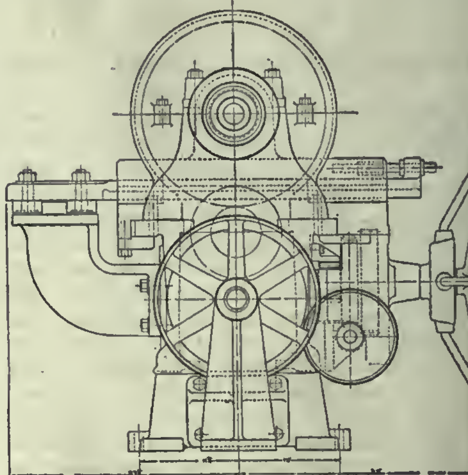
The carriage which is 36 inches low, is fitted with adjusting jibs at the back and the front. The feed rack is of extra strength, having a face of 2½ inches with 3 d. p. Carriage feed is of the friction type, a face with a contact of 1¾ inches by 9 inches diameter. This is located in the hub of the pilot wheel. Feed is obtained from a two-step pulley using a 3-inch belt. The carriage apron is of the heavy double plate type, back geared plate made of steel with bronze bushed bearings. The spindle thrust is taken by a special ball bearing fitted to the forward end of the rear bearing. The approximate weight of this machine is 10,000 pounds. The cut shows the lathe adapted for shell boring, but it can be readily converted for rough or finish turning by changing the attachment on the carriage. The machine is fitted with a profiling fixture and can be supplied with a turret if desired, by the manufacturers, H. W. Petrie of Montreal, Ltd.

7.5 MM. BORING LATHE

The Canada Machinery Corporation, Galt, Ont., has recently placed on the market a lathe for boring 75 mm. shells. The design of the lathe is new and was developed by this concern after an extended experience in the manufacture of shell making machinery. This lathe is of substantial construction, an essential feature in machines of this type, while it is also simple in design and easy to operate.

The bed is unusually deep and heavy and is made with solid cross bridges. It is also built with two large flat sheers on which the carriage traverses, ensuring ample wearing surface. The head is of strong construction, ensuring great rigidity at all times.

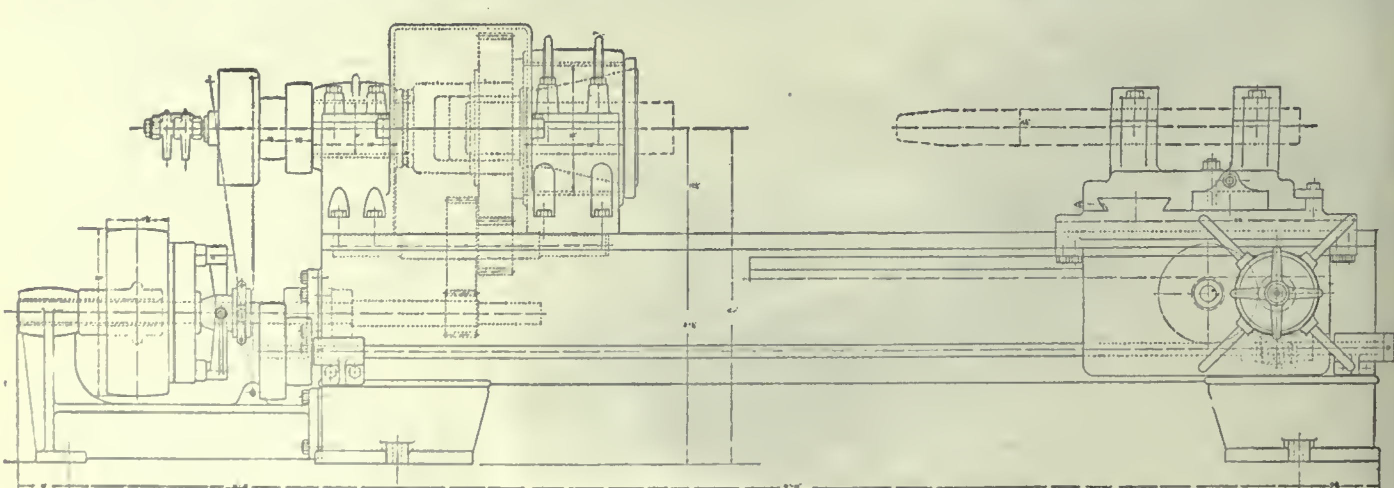
The spindle is a semi-steel casting of large size and is provided on one end with a compressed air cylinder operating a collet chuck. This chuck is controlled by a conveniently situated air cock and is so arranged that it extends within the



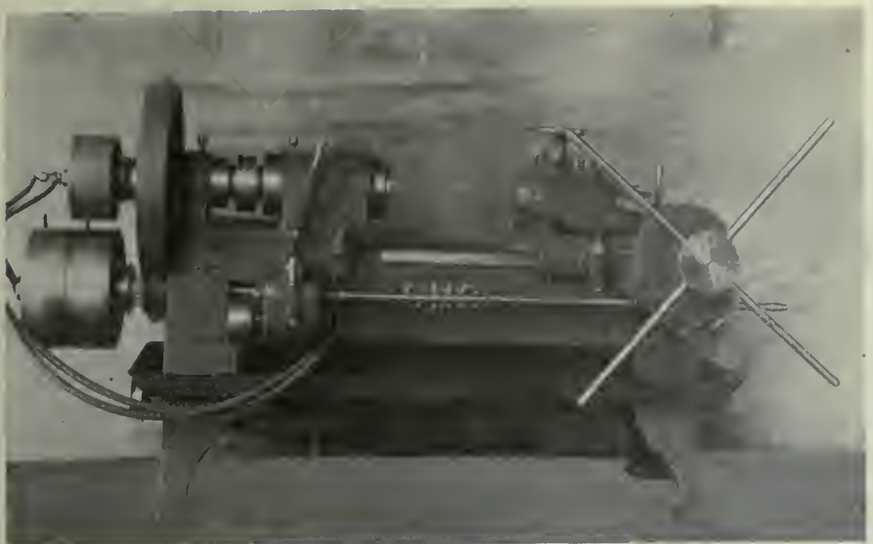
26-INCH SHELL LATHE. END ELEVATION.

spindle, thus bringing it within the front bearing, ensuring rigidity. It is instantaneous in action and will keep its alignment under the heaviest work. The spindle has taper bearings which are of large size, the front bearing being 7 inches diameter by 12 inches long and the back bearing 5½ inches diameter by 5 inches long, provision being made to take up the wear. One spindle speed only is provided on the regular machine but a two-speed countershaft can be supplied, at an extra cost, which will give two speeds of desired range.

The feed to the carriage is simple and efficient, obtainable by means of a feed rod which carries a heavy worm, which



26-INCH SHELL LATHE. SIDE ELEVATION.



75-MM. BORING LATHE.

by means of a conveniently situated lever engages a worm wheel and pinion operating on the rack bolted to the bed. This feed rod is driven through a two-speed gear box, which, in operation, is driven by a belt from the spindle. The feed, being thus belt driven, offers particular advantage over a positive driven feed insomuch that it may be left engaged to assist the operator in the difficult bottoming operation, which is impossible with the positive driven feed, thus increasing the speed of this operation.

An automatic trip is provided in addition to the hand trip. This trip is set at the desired point and the bars in the turret set for the correct depth.

The turret is mounted on a cross slide on the carriage and is solid and massive throughout. It is provided with three holes to hold the boring bars and is traversed across the carriage for different operations by means of a rack and pinion operated by a large hand wheel on top of the turret. A suitable stop is provided for locating each bar centrally and a clamp handle is also provided for locking securely in position.

A pump of approved design is provided to supply an ample and constant flow of cutting lubricant to the boring bars and the piping is so arranged that the bar which is working is the only one to receive this supply. A steel oil pan is provided to collect the cuttings and to return the cutting lubricant to the pump.

The gear ratio of drive is 5.17 to ' The fast and loose pulleys are 16 inch diameter by 5¼ inches face, the speed being 5.75 r.p.m. The holes in turret are 1 15/16 inch diameter. The weight of the machine is 3,000 pounds and floor space occupied 3 feet by 8 feet, cubic measurements, 150 cubic feet.

OVERHEAD CARRIERS AND HOISTS FOR MUNITION PLANTS

Adequate means for the handling of shells as they pass from one machine to another is a big factor in quantity production and an item which affects the balance sheet to a large extent.

The tracks conveying devices manufactured by the Richard Wilcox Co., London, Ont., have the advantage of years of prior development and experience in their production. The track used for the shell is a trolley track made up of a formed tube of sheet steel totally enclosing the carrier. These tracks are furnished in any length and adjustable brackets are furnished for support. The track section permits the use of switches, curves and turntables to any desired extent.

The carriers are made in plain or ballbearing types and for extremely heavy loads a sufficient number of carriers are linked together for strength and flexibility.

DETAIL VIEW OF CHAIN BLOCKS AND CARRIERS.

In the installation shown the shells are passed from one machine to the other on tables but are picked up off the table and placed on the machines by the block and tackle suspended from the carriers.

KNURLING MACHINE FOR 75 MM. SHELLS

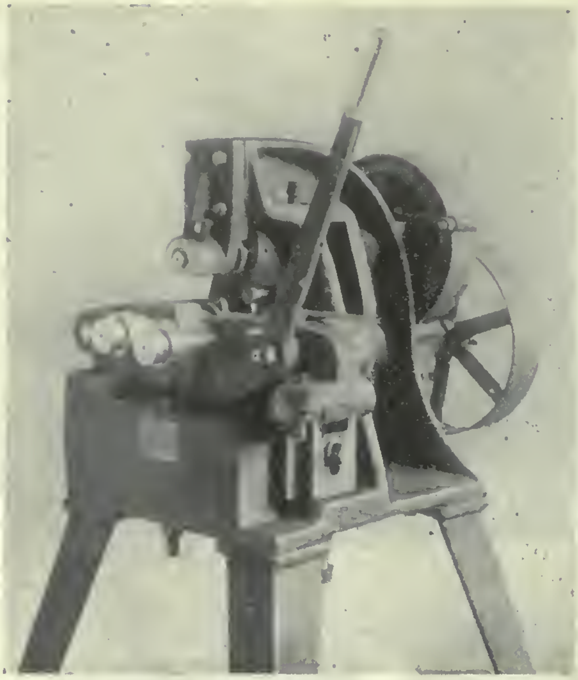
The Canada Machinery Corporation, Galt, Ont., has designed a new machine for rolling the knurl on the seat for the copper band on 75 mm. shells. The machine has already achieved considerable success, for it is being used by four of the largest makers of 75 mm. shells in Canada and also by a number of firms in the United States. The machine is also being built to use for the same purpose on 4.5 inch and 155 mm. shells. By substituting plain rollers for knurls the machine can also be used for rolling smooth the bourellet on the millimeter sizes of shells.

ARRANGEMENT OF CHAIN HOISTS AND CARRIERS SERVING LATHES.

The machine is of simple but strong construction as will be seen from the accompanying illustration. The operation of knurling is done as rapidly as the shells can be handled, the mechanism being so designed that no chucking is necessary, thus resulting in high production.

When the shell is placed in the machine it rests on a pair of adjustable cradles with its base up against a stop on the head to locate it in the correct position. A lever which is in a vertical position is then pulled down to the horizontal, this motion lifting a cradle or yoke which carries the two lower knurls and outer rolls. A steel eccentric 2½ inch face, acting on a roll of the same width, operated by the lever, which is 2 feet long, brings the shell into contact with the knurling collars. The outer rolls on the lower knurling spindles, referred to above, hold the shell in line while in operation. The motion of the yoke is governed by means of an adjusting screw located at the front of the machine.

The upper knurling collar only is driven, the lower knurls revolving by friction. The knurling collars are 2 15/16 inches diameter with 3/16 inch face, the



KNURLING MACHINES FOR 75 AND 155-MM. SHELLS.

upper one being driven by a 1 5/16 inch spindle running in long phosphor bronze bearings while the lower knurls are fastened to steel spindles running in bearings in the yoke. The spindle carrying the upper knurl runs at 100 r.p.m. and is geared up to 300 r.p.m. at the driving pulley. The outer end bracket bearing of this spindle is removable for changing knurls.

When the knurling operation has been completed, the lever is raised up, the lower knurls come away from the shell which now rests on the adjustable cradles. The cradles arrest the motion of the shell and hold it clear of the knurling collars while it is being removed from the machine, as is the case when the shell is being placed in the machine. The knurling machine weighs 1,200 pounds and occupies a space 36 inches by 48 inches.

When this machine is built for rolling the bourellet, plain rols are used instead of knurls. In this case all the rolls are power-driven through gears in the head of the machine. The shell is supported in the same way and the yoke is also used in the same way as for knurling. When rolling the bourellet the nose of the shell lies towards the head of the machine.

CUTTING OFF AND BASE FACING MACHINE.

No doubt 6 in. and 155 m.m. manufacturers will readily appreciate the operating advantages of the "Improved" No. 2 Globe cutting-off and base-facing machine, illustrated herewith.

In this machine, a powerful, easy drive is obtained by two sets of steel gears, 3¼ in. face, having ratios of 5.75 and 6.30 to 1. The shifting mechanism consists of a positive steel clutch of ample proportions, operated on the driving shaft by a steel lever conveniently placed. Plenty of belt surface is assured on the crowned 18 in. dia by 6¼ in. face driving pulley, eliminating the tight belt with its usual troubles. Equally satisfactory results are obtained, driving from either lineshaft or countershaft.

The chuck is integral with the spindle. Forgings are held by a simple method, sometimes called the "pot" system, consisting of 4 hardened steel set-screws of generous size. A second set of hardened steel set-screws acts as a concrete inside the spindle.

Several other minor changes have also been made.

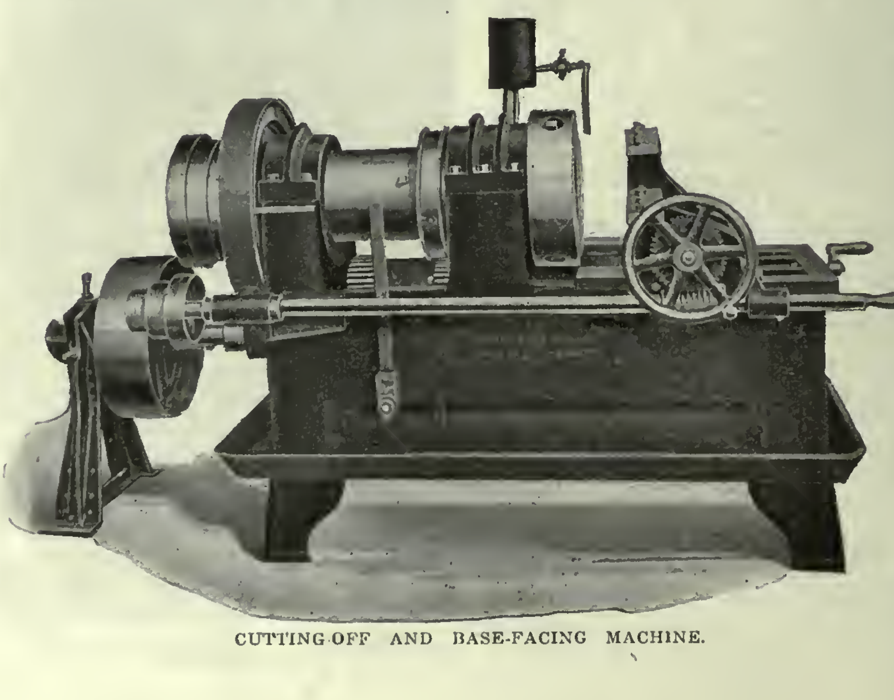
This machine is manufactured by The Globe Engineering Co. Ltd., Hamilton, Can. Additional equipment has recently been installed, making early delivery possible on further orders for these machines.

MOTORSHIP ADVANTAGES

By D. Street.

THE super-Diesel internal combustion engine will play a very important part in the near future in ship design and propulsion. This type of engine was invented by Otto, perfected by Daimler, and brought to its highest state of efficiency by Diesel and Junkers. Its operation is based on the principle of rational conversion of coal into power—in other words, it utilizes this fuel in the form of the by-products of coal, such as gas, benzol, and other inferior substances which are derived from the distillation of coal in coke ovens, gas retorts and gas producers. This method gives a distinct advantage in multiplying the usefulness of a ton of coal, resulting in a higher output of heat, light and power from the same. The values thus added to the national income are difficult to estimate. This type of engine has also opened up a new and extensive field for the exploitation of mineral oils, such as crude petroleum, etc., which formerly only had a limited range of usefulness and has set a new value on oil lands.

The oil engine has now become dominant in the navies of Europe, and the imperative need of the most up-to-date equipment applies to merchant vessels as well as those for war purposes. Motorships are coming to be recognized as far more economical than those propelled by steam, not only in economy of fuel and labor, but in the greater cargo space that the same sized ship of this type affords over that of a steam-propelled vessel. Due to the absence of boilers and funnels, motorships are clear of many working obstructions and give large unrestricted room for loading and discharging.



CUTTING-OFF AND BASE-FACING MACHINE.

CAN TAKE NO CHANCE ON SHELL INSPECTION

Defects Should be Caught Right in the Machine Making the Faulty Operation

By J. H. R.

The chairman of the Imperial Munitions Board in discussing shell making with a representative of this paper some weeks ago, made a point that is brought out in the following, viz., that each shell is a unit, and is either good or bad by itself. There is no such thing as a fairly good shell. It is either good or bad, right or wrong. Moreover, it may be the first operation or so that determines this. This article points out the need for close attention to points where the 100 per cent. efficiency standard is being broken down.

FEW problems relating to the manufacture of munitions have created more difficulties than that of inspection, and yet this important factor has often been so sadly neglected or overlooked as to result in gross inefficiency. The essential bearing that thorough inspection has to the successful production of munitions was not clearly recognized during the incipient stages of this industry, the consequence being that the percentage of rejected shells, due to faulty forging or machining, was very frequently so large that drastic measures were required to prevent an occurrence of such possibilities. One of the primary considerations in connection with the manufacture of ammunition is the high degree of accuracy that is required in the various operations; not that the working limits are finer than any hitherto performed, but that many of those firms receiving initial contracts had not been accustomed to work to the standardization necessary for quantity output.

The Supervisor's Work

Some impressions of a supervisor of inspection are set down in the following statements. "When it became apparent that all engineering concerns in Canada would be given the opportunity to assist the arsenals in producing the maximum quantity of ammunition that would be required, many contracts were accepted on the supposition of what had done another might easily accomplish. With the possible exception of a few tool manufacturers it is doubtful if more than 25 per cent. of the original shell makers had been accustomed to working to the fine limits or low tolerances required in shell specifications. With their past experience only as a guiding influence many firms failed, utterly, to realize the part which inspection would play in determining their intimate degree of success.

"It would be serving no particular purpose to enlarge very much of the number of failures brought about by the lack of foresight shown by some in their desire to ignore, or at least minimize, efficient shop inspection, but some of my experiences would have been almost ludicrous if they had not been associated with such loss of time and material, and waste of valuable highly skilled labor. For instance, in the early days of the war it was a common sight to see some shops making the most elaborate inspection of their product along similar lines to the Government and immediately before submitting to the same, while at the same time there were not enough inspectors at the different machines to check the work at a very low percentage. The result of this policy, in many cases, was that their shop inspection would send back for repairs anything from 50 to 75 per cent., and probably reject as scrap 25 per cent.

The Better Way

"By an efficient shop inspection whereby only reliable inspectors were placed at the various machines to check up 100 per cent. of the work, with full authority to immediately stop a machine at the first sign of faulty work, the following would have to and can be obtained:

(a) Operators on machines are able to give all their attention to the actual machining details and go straight ahead without the anxiety of knowing whether he was making bad work or not, as the inspector would be the person who would at once stop him on the first appearance of defective work. The tool-setter or foreman would become immediately acquainted with the trouble, so that the tools could be adjusted or repaired, or altered to suit the required conditions. Where the machine is at fault it may be necessary to stop the same until such time as it can be fixed or replaced. By this practice it is virtually impossible for spoiled shells to accumulate between machining operations.

(b) When shells have to be rectified a considerable part of the profit is lost on the shell, and good men's time is utilized in repairing the same when it might be better applied to the country's needs in other branches of engineering. Very few firms stop to consider the cost of this repair work, the machine installation required, and the number of shells that are returned for repairs, many of which eventually find their way to the scrap heap.

(c) A shell when lost in the machining means that a shell has been forged for nothing; surely this alone is a loss to the country in fuel, material, and labor, and involving the additional work required in replacing the shell that has been destroyed.

A Dangerous Trick

"Some superintendents are apt to exclaim—'We can afford to lose five per cent. scrap'—but never stop to consider how they are going to regulate it at the said five per cent., for as each shell passes through exactly the same sequence of operations it is obvious that if a bad piece is produced from a machine it is logical to assume that the same fault will occur on the next piece or subsequent shells at this specific operation, and considering that in the manufacture of some types of shells there are from 35 to 40 different operations, there is every opportunity of making 25 per cent. of scrap when the management are satisfied to tolerate a five per cent. rejection. A far better viewpoint is to look for 100 per cent. perfect, and even with good inspection, the best tooling, rigid machinery, and above all positive stops, errors are almost certain to occur, so that on the expiration of the contract if it is found that three per cent. has been rejected by faulty machining and in the Government inspection, the firm getting such results can feel highly satisfied.

Must Have Control

"To obtain these results requires an investment of five per cent. for inspection, in relation to the value of the article, providing the following conditions are adhered to. Procuring a man in charge of inspection controlling an organization entirely separated from the production department; that is, the man must be an engineer and thoroughly capable of taking responsibility, and guaranteeing absolute first class work to the directors who engage him. He must have a free hand to control any machine or group of machines, which is making material contrary to the drawings or specifications.

"By maintaining a very high quality of work throughout the shop further inspection of the finished article is hardly necessary except where parts are liable to become affected by subsequent operations. With detail inspection the great advantage to be derived is the regular flow in large quantities which pass through the Government inspection showing a minimum of defects, and is the state in which the Government expect it to be in when it reaches this department, as most Government inspectors have a very strong objection to performing inspection work for the company making the shells—work that should have been done in the shop, or further at the very machine that performed the operation for which the shell has been rejected. Slight errors, and cases where the operators consider they will take a chance, often exclaiming—'That is good enough'—will eventually lead to trouble before the shell passes the final Government inspection. The rule for inspection must be to insist on perfection of the product at each machine and in every detail, and then and only then will the contractor get the results which he hoped for and expected at the time when he took the contract."

Are Standing the Test Well.

ALTHOUGH reports that have been spread for some time might lead Canadians to expect a falling off in the number of shops operating, reports of closings are few and unusual.

So much was heard of drawing the deadline between essential and non-essential industries, and closing off the latter, that drastic measures were always supposed to be just around the corner.

As a matter of fact Canada's war performance is demonstrating that her industries, for the most part, are not of the non-essential kind.

The very fact that so many of them are being recognized by the War Board when they want to enter the market for supplies is sufficient proof of this. In many cases, although a shop may not have a direct contract, it is working on a sub-contract, and in this way helping to speed up production.

Some of the foundries making lines "that can wait" are suffering from a lack of pig iron or scrap of good enough grading to make a fit substitute.

On a broad scale, though, industrial Canada is standing the acid test of essential or non-essential in good shape. It is good evidence that Canada's industrial life is based on concerns turning out necessities rather than things that people imagine they want, but in reality are much better without.

Can You Run a Quarter Mile?

DOES the average man take care of himself? The individual might be inclined to answer such a query in the affirmative, but having given the nod of the head, he might have quite a time convincing any person else that he was right.

Here's what one real authority has to say of the matter: "Words are inadequate. Neither tongue nor pen can do justice to this subject. The average man would puff and blow like a porpoise if he attempted to run a quarter of a mile. He would be stiff and sore for days if he walked five miles at a brisk gait."

And the chances are that the man who made that statement was mighty close to absolute fact. Here and there is an exception to the case, but these exceptions are conspicuous by reason of their rarity.

If men were asked why they allow their muscles to become soft, flesh flabby and joints wheezy, they would have an array of excuses that would shape up fairly well. But sifted out, it would come to "Can't be bothered."

"Can't be bothered" in reality accounts for a heap of stuff that manages to crawl away under some other guise.

The man in the city is in many cases a poor prune when it comes to physical fitness. He rides in his auto or on a street car to work, rides to lunch, rides home, and imagines he's a regular bang-up Adonis if he can cut the lawn and carry out the garbage without having a vacation between the movements.

But when it comes right down to brass tacks there are few people who bother keeping in shape. The loss is to themselves, to their employers and the nation. And in the aggregate the loss in efficiency to the nation is staggering, for no man can allow himself to degenerate into a jelly-fish and keep the consequences entirely to himself.

Paving the Road For High Prices

THE following is a sample of the stuff that runs the gauntlet of the Ontario press every few days:

> Ontario housewives will have to go a little light on preserving this fall as the fruit crop of the province has turned out very poorly. Cherries, plums, pears are all very scarce, and apples did no do so very well, either. Peach trees in the Niagara peninsula were killed by the frost to the extent of about 10 per cent.

Cherries are the first on the list to reach the market, and there are cherry trees all over the country breaking for the want of some person to pick the fruit.

The same talk of winter killing of peach trees gets hatched over in the Niagara belt every year just as sure as the water runs over the Falls. Niagara's fruit correspondents would indeed be a flotilla of lame ducks if they couldn't get that old winter-kill story out of cold storage and let it prance around a little every spring and summer.

What's the idea? To get the people ready to pay top prices for fruit? Or to get them at the stage where they'll grab at the first grist of colic apples that get peddled inside the city limits? Or to educate 'em so that green gooseberries at 20 cents a quart will look like an 8.30 bargain, well worth grabbing for?

The prices for fruit, between the embargo and the price grabbers, will be high enough, without the press getting up on its hind legs and hollering in advance that the housewife had better be prepared in advance to be mulcted to the limit for every pint of fruit she manages to tuck away in the cellar for winter use. She knows mighty well it will happen without papers going to the trouble of putting grease on the skids for the price boosters.

Our idea of good luck is for a family to go through the cherry picking season without any of the members carrying a broken leg in a sling.

Before you start a strike, make certain that it isn't going to make it easier for the German troops to do the same thing in a different way.

It's a fatal mistake for the man who has been operating an automatic machine to imagine that as a mechanic he's not far removed from the expert tool maker.

A man with a mania for figures has it that about 12 million men of all armies have seen front line service, and of this number, according to reports from the various capitals, some 18 million have been taken prisoners. Statistics are surely interesting and instructive.

Your War Contracts Will Stop Some Day

THE manufacturers of Canada who can line up with the war group have little to worry about at present in regard to business. They can get it—all they can handle. And the great percentage of it is in the line of repeat operations and long runs.

There is no need to worry about the sales and collections. The only trouble about the latter is at times in the matter of adjustment for rejects and the labor loss necessary to find the defect that makes the rejection necessary.

Are the Canadian firms, the steel and iron concerns, the machining plants, big and small, living in the present alone, or are they looking to the future? The fact that you have been a success in turning out war orders is not proof positive that you are going to be a success when the war work closes and you have to get out and hustle for business in the open market.

The real test of Canadian efficiency has not yet come. It is coming in the future.

Remember this. Industrial plants in Canada are keyed up for production—for very large production. They have turned out an amount and a quality of which they can be proud. Canadians were afraid of munitions business when it was first a possibility. They shivered at the fuse game. But they went in. They turned out successful. They made munitions for Canada, for Britain, for United States and other Allied nations.

But don't get away from this. This "keyed-up" process has not been common to Canada alone. The plants of other nations are under the same strain.

Their organization, built to fight the same battle as we are fighting, will, at the termination of the war, be out to meet us in open competition for our own markets and the markets of the world.

If their production methods are better than ours—if they can make better goods at our price—if they can make equally good products at a lower price—the Canadian industrial world is going to be in for hard sledding and a poor session.

The Canadian munitions producer with the big organization has the government as the responsible party to pay the bills—it has as its sales force the dump cart of war need at its factory door, and the dump cart has been backed up there for a good many months.

Now, then, look ahead. When the government ceases to order, and the dump cart moves away, what is going to happen?

Unless the firm has kept its production costs on a level, or something approaching it, with peace time, competitive prices—unless efficiency has marched along with this great volume of business—there is going to be a season of discharging hands that will make the employment office dizzy.

This is not alone the opinion of CANADIAN MACHINERY. *It is the belief of some of the very best leaders of industry in Canada at the present moment.*

Men who realize this are men who see in the present volume of business not simply an opportunity for profits, but a responsibility for maintaining the industrial and labor equilibrium in the period following the end of the war.

The men who do not and will not realize this situation are those who rush into the labor market and take 500 hands—use them as long as it suits their purpose and immediately after fire them into a glutted labor market. To them there is no human side in industry. To a large extent they undo the work of manufacturers whose chief delight is in the welfare of their men, and make it doubly hard to kick down some of the nasty barriers that fanatics persist in building up between capital and labor.

Right now, when business is good—when you can afford to do it—look ahead.

Don't wait until the Allied governments come around and say, "Gentlemen, we have no more war orders. You will have to do something else now or close up your shop."

Don't be caught. Don't have to tell a deputation of your workmen that you don't know on what date your plant will re-open.

MARKET DEVELOPMENTS

Hot Weather Not Helping Production

Hard on Men at Furnaces and Rolling Mills—Brisk Demand For High-Speed Steel—Scrap Situation is Not Showing Any Signs of Improvement

THE weather has been much against high marks in production in the steel, iron or rolling plants during the week, and it is only fair to assume that the figures have shown a falling off. Against this, however, there has been a season of fairly cool weather, making good production possible and quite easy to maintain.

Reference is made in several despatches from American points to some Canadian bars having been sold to non-essential industries in the New England states at a price above the figures fixed by United States government. One of the steel trade men of Canada who knew of the case in point said that the affair took place some time ago—in fact the beginning of the deal was at a time before United States entered the war, and the amount in question was not large. He made it plain that the practice is not now carried out, and expressed surprise that the incident was deemed of sufficient size to ever get into print.

Plants turning out pig and steel have quite a problem in keeping the fine balance necessary in the disposal of their output so that the foundries and machine shops shall be equally well served.

The question of the supply of scrap is coming to the front more than it has ever done before both in this country and United States. In the Republic there is a regular combing-out process in operation for old material, and a determined effort is being made to bring it all from any of the hiding places where it may be taking cover. But the railroads are holding tight to old cars, locomotives, etc., and they are also abandoning a much smaller quantity of old rails than formerly. U.S. mill men are also raising another point that does not occur to the casual observer. Many of the plants forging American orders in Canada are served with U.S. steel. These are machined in this country, and the scrap turnings from all this is used up in this country, thus denying the American mills of considerable material. The plate mills are still the favored lot in the war group, and continue to draw a very large tonnage of raw steel. The effect of this is that rod and wire mills are running only about 60 per cent.

Dealers in high speed steel are doing a big business now—in fact the chances seem to be that their high figures for volume of trade are being touched this quarter. There are many plants just on the verge of the production stage, and when this is the case the demand for high speed is brisk. This condition, added to the number of plants already operating, and the scarcity of skilled men, makes a situation that is very favorable to the dealers in high speed goods. Rumors were heard of a new list on carbon goods, but it has not yet materialized.

THE HOT WEATHER HAS A TENDENCY TO PULL DOWN PRODUCTION TOTALS

Special to CANADIAN MACHINERY.

MONTREAL, July 22.—The hot wave of the past few days coupled with the general holiday season, has acted as a quieting feature on business generally. As is usual under these conditions the steel mills and foundries have been forced to curtail slightly on production. Continued activity in the munitions industry is still a feature. Some plants under construction are nearing completion and in a few weeks operations, are expected on a production basis. For this reason the machine tool trade is quite active and manufacturers are exceptionally busy in making the desired equipment, the bulk of which will be made in local plants. Old materials are quiet with scrap metals firm and stronger.

Hot Weather Affects Mills

Conditions are relatively unchanged from those of the past few weeks. The demand or rather the requirements continue quite heavy, particularly for ship yards and the munitions plants. Local rolling mills have been affected by the extreme heat of the past few days and the tonnage output has suffered somewhat in consequence. However, the favorable weather during the earlier portion of the month enabled them to maintain production at a good figure, so that unless the hot spell is prolonged the mills anticipate an early return to previous activity. Several steel foundries are again busily engaged in making billets for the 9.2 inch shells and other sizes.

Plants working on the machinery of the large shells are well under way and are rapidly attaining the steady production stage. A feature that may serve as a basis for an early revision in the distribution of Canadian steel supply, is the report that some steel has been disposed of to firms in the States that are not duly entitled to the same under present conditions. If investigation proves such to be the case the Government may take steps to prevent a recurrence of the movement Dealers here report a steady enquiry with slightly better delivery on material coming from United States mills. Quotations are firm and well maintained.

High Speed Steels Active

Now that many plants are nearing the production stage on American shell contracts, the demand for high speed steels is showing a relative increase. Local manufacturers of small tools, such as cutters, reamers, etc., are very busy, and as stated by one large concern—"The apparent shortage of skilled labor for the making of tools in shell plants, has added to the demands upon the small high speed tool manufacturer, so that our business in this respect has shown a steady increase." Prices are steady and well maintained at about $2.25 per lb.

Metals Steady

The general metal situation is without feature. Copper is higher and supply is scarce. Tin is still uncertain but price is unchanged. Spelter has weakened. Lead is dull.

Copper.—The market here has a strong tendency owing to the fact that metal is hard to obtain. Little American copper is available while the general demand is good. Dealers are now asking 30½ and 31½ cents an advance of ½ cent per lb.

Tin.—The supply of tin here is ample to meet immediate requirements but dealers state that delivery of metal is very indefinite. The quotation of $1.10 is still maintained but is a nominal figure.

Spelter.—A quiet week in spelter has resulted in a weaker market, as reflected in a ½ cent decline locally. Dealers here are now asking 11 cents per lb.

New Machinery Desired

The demand for machine tools at the present time is quite active, not that many new orders are being placed, but the requirements for several new munition plants are receiving considerable attention. In the aggregate the bulk of this equipment will be of the special purpose type, and much of the machinery for the local plants is being constructed in the city. It is notable that, with few exceptions, the bulk of inquiries is for new machines, some few that have seen service have been disposed of. Dealers report an active effort on the part of certain holders of old machinery to offer them for sale, tempted by the condition of the market, but as a lot of this is unsuited for existing conditions, the dealers are not inclined to handle this business. Owing to the abnormal demand for supplies now existing in the States, dealers report some difficulty in getting delivery on equipment coming in from American points. Canadan small tool manufacturers are particularly busy at the present time.

Some Scraps Scarce

Apart from the marked scarcity in some scraps the situation is comparatively devoid of feature of any kind. Dealers report a steady but quiet business. Slight increase has been noted in the non-ferrous field and dealers are asking prices, for old copper, slightly in advance of last week. Crucible and heavy coppers are up another cent, the price quoted being 24½ cents. Composition turnings are ½ cent stronger at 23 cents. Medium brass is quoted at 13 cents, an advance of one cent per lb. Scarcity of cast iron, both machine and stove plate, has made these markets stronger. The former is quoted at $35 and the latter at $24 per ton, the advances being $1 and $5 respectively. Heavy lead is now quoted at 8 cents, an advance on the week of one cent per lb.

POINTS IN WEEK'S MARKETING NOTES

Toronto dealers state that the demand for high-speed cutters is greater than ever.

Steel and iron plants have a problem trying to dispose of their supply so as to keep the proper balance between pig iron and steel.

Heavy melting steel and machinery scrap are much in demand. Not much comes to the market as the government takes the munitions plants' scrap, and many large firms sell directly to the trade.

Copper producers are not satisfied with the new price and are working for a figure around 27 or 27½c. The price standing for some weeks before that was 23½c.

A Pittsburg despatch states, "the country is being combed for old material." This helps only a little as railways are holding tight to old cars and locomotives, and abandoning smaller quantities of old rails.

United States points claim that much unfinished steel is leaving the country, and being finished inother countries, thus depriving U. S. of the scrap metal from the process.

Plate mills are drawing an unprecedented supply of raw steel, making it more difficult for other plants to get a supply. Rod and wire mills, sheet mills, merchant pipe and bar mills are not drawing 60 per cent of their former supply or raw steel.

VERY HEAVY CALL ON HIGH SPEED GOODS

Toronto Dealers Say That Run During Past Weeks Has Touched the High Mark

TORONTO.—The hot weather seems to make no difference on the volume of business that continues to pass through the houses dealing in machine tools, equipment and supplies. Large plants that have been getting ready for new contracts are receiving generous deliveries of machinery, and in some cases it is expected that the first operations will be under way in a few weeks.

Jobbers are handling greater volumes of trade than has passed their way for some time. They find deliveries much more prompt than they have been for some time. Prices have remained for the most part the same as quoted last week.

The copper situation, while based on the higher price level, has few features locally, although it is attracting no small amount of attention in other sections.

The Steel Situation

Canada is handling a large amount of steel now. Our own men in many places are being trained to steel mill operations. A few years ago there were few furnace or roller men in Ontario, but their number is rapidly increasing. Steel men find that the Canadian, when trained, makes a good steel mill man, and can hold his own in any effort made to speed up production.

There is quite a problem facing the iron and steel men of the Dominion at present, in trying to keep a nicely adjusted balance between the amount of material going out as pig iron and passing over to the open hearth furnaces for further finishing in the plants. There might be an easy tendency on the part of the mills to put through a larger amount than usual for the steel trade, for there is an enormous demand just now for plate, sheet, etc. However, there is a nice balance that must be kept adjusted between pig iron and steel, for in so many cases the machine shop and foundry are to all intents and purposes part of the same institution as far as the finished product is concerned. As one steel man remarked to CANADIAN MACHINERY a few days ago, "What would be the use of going ahead and filling up our steel plant and shutting off the foundrymen? Such a course might give us a slice of good paying business for a time, but it would be mighty poor business in the end for steel men to try and disturb the balance between foundries and machine shops."

As a matter of fact there are not many foundries on essential work that are pinched for pig. Against this there are lines that are not being well supplied, but in many cases they are not in the war group.

Scrap Is Scarcer

The scrap metal trade is not brisk. Buyers are anxious to get material to sell quickly, but that is the kind where there is the greatest shortage. Heavy melting steel and good machinery scrap are much desired just now. At U. S. points the shortage is quite marked, and firms are willing to bring the stuff a considerable distance, paying the excess freight charges in order to secure the metal. Many sales for the more desirable sorts are made at a maximum price with the allowance of 3½ per cent. for brokerage added to that.

One local dealer who was in Buffalo during the week reports that the yards there are making a strong bid for available scrap, as the mills in that district are urgent for a supply of second-hand material.

The Copper Price

While the local quotations on copper remain unchanged this week, there are signs that the price problem has not yet been finally adjusted, and changes later on may have a distinct bearing on the situation. On May 23rd when the price was fixed at 23.50c, it did not meet the approval of the producers, and they did not agree to the price or date. The sales made after May 23rd by producers were generally drawn, not at a definite price, but at Government price ruling at time of the delivery for which the copper was sold. As the War Industries Board gave out that the price was fixed at 23.50c until August 15th, and as the president approved same, consumers accepted contracts for July and delivery before August 15th, worded at the Government price at time of delivery, having the positive official statement that price up to that date was 23.50c, and sold their manufactured goods against their copper purchase on this basis. Now they find they have to pay 26.00c or 2½c per pound higher on their undelivered contracts.

Machinery Trade

Several large deliveries were completed this week, the equipment being for plants that are now ready to begin work on their new orders. Some of the contractors complain of annoying delays, but these are due to some sub-contractor falling down on delivery of a minor part.

The demand for high speed steel has never been at a much higher level than it is right now. Some local dealers state that the past week's business on cutters alone has been away beyond the average. Munitions shops make heavy demands on high speed goods.

There was a rumor in some of the places of business to-day that there would soon be an advance in carbon goods. This is referred to Canadian firms, but so far no new list showing a recent increase has arrived from leading Canadian makers.

LARGE ORDERS FOR MACHINE TOOLS

Figures Are Still Spoken of in Millions in Regard to the Purchases

Special to CANADIAN MACHINERY.

NEW YORK, July 24.—Large supplementary contracts for guns, shells, aircraft and airplane motors are on the point of being placed by the Government; in fact, several substantial orders were released in the last week and manufacturers who have called for prices on large lots of tools for shop equipment are only awaiting Government approval to close contracts for the machinery. The demand for heavy tools used by shipyards and ordnance makers is very active and there is a fair inquiry for small and medium sized tools. Some of the manufacturers of large tools have already begun plant extensions to keep pace with the requirements of the Government.

Government approval having been received by the Wright-Martin Aircraft Corporation for its programme to largely increase output of Hispano-Suiza motors, orders for 600 machine tools to be installed at the Long Island City plant have been distributed; 40 motors a day will be constructed at Long Island and production at the New Brunswick, N.J., plant will be increased from 500 to 750 motors every month. In addition, parts of motors will be manufactured at the Plainfield, N.J., factory, previously owned by the Bosch Magneto Co., which was recently acquired by the Wright-Martin interests from the Alien Property Custodian. The Willys-Overland Co., Elmyra, N.Y., has received an additional contract for Liberty airplane motors which it will manufacture at its Willys-Morrow plant. The Standard Aircraft Corporation, Elizabeth, N.J., having large Government contracts, is about to increase the size of its factory.

Another Government contract for heavy type of Browning guns has been awarded to the Marlin-Rockwell Corporation, New Haven, Conn., and other New England gun makers have put out large lists of tools to increase plant capacity in anticipation of Government orders. The Taylor-Wharton Iron & Steel Co. is buying additional machinery for its Tioga gun plant at Philadelphia. The new shell plant at Chicago belonging to the Symington-Chicago Corporation, is already under construction and an order for about 500 tons of steel has been placed for additional buildings. The Studebaker Corporation of South Bend, Ind., which already has received Government war munition orders ranging from $20,000,000 to $50,000,000, is building a new shell plant to cost $300,000, having been assured of all the shell orders it can handle for the next two years, according to reports in the trade. The Wisconsin Gun Co., Milwaukee, which is now making 3-inch field pieces for the Government, has placed a large order for tools which will double its ordnance capacity.

A shell maker in the Central West has placed an order for 150 single-purpose lathes with a Cincinnati tool builder. The New York trade has received two inquiries for shell-making tools from South America. The John Thompson Press Co., New York, and the New Departure Co., Bristol, Conn., that are making war munitions, have purchased additional shop equipment.

Builders of tractors and gas engines have been buying machine tools in the Chicago market, including the Interstate Motor Co., Muncie, Ind., the Falls Motor Corporation, Sheboygan Falls, Wisconsin, and the J. I. Case Co. Threshing Machine Co., Racine Wisconsin.

Railroads are releasing some orders, the Chesapeake & Ohio having purchased large too's in the East and the New York Central having made purchases in Chicago. The Pennsylvania Railroad is also buying equipment for its Altoona and Marietta, Pa., shops, and fifteen other railroads are actively in the market for machine tools which will cost $5,000,000 in the aggregate.

Two ship berths with auxiliary shops and erecting buildings will be constructed at the Brooklyn Navy Yards by the Bureau of Yards and Docks; 40,000-ton battleships will be built on these ways.

D. H. MacDOUGAL BECOMES HEAD OF THE NOVA SCOTIA STEEL AND COAL CO.

Announcement is made by the officials of the Nova Scotia Steel & Coal Co. that D. H. McDougall has taken the position of president of that company. Mr. McDougall has for some time been the general manager of the Dominion Steel Corporation. Although none of the officials interviewed would admit it, the new appointment may be the outcome of the failure of negotiations which were pending some time ago for amalgamation between these two large concerns.

It is understood that F. H. Crockard, who was brought to Canada from the Southern States to take charge of the Nova Scotia Steel business had been quite anxious to see the amalgamation brought about and that the failure of this was primarily the cause of his leaving the Scotia company. The announcement of the dropping of these negotiations was made in these columns some weeks ago. Mr. Crockard had had a long experience in the steel business of the United States and was reputed to have been about the highest paid official of that industry in Canada, receiving, it is reported, a salary equal to $100,000 per year, together with certain bonuses on production.

Some surprise will be occasioned by the announcement that Mr. McDougall has been appointed president of the Nova Scotia Steel & Coal Co. as the Dominion Co. with which he has been associated for some time has very large and important undertakings at the present time, many of them being based on war contracts which that company has taken on from the Dominion Government. Mr. McDougall is essentially a Canadian in every sense of the word, in his training, and in his practice, and in his knowledge of mining conditions, in the eastern part of the Dominion. His training includes a first hand knowledge of the iron ores of Newfoundland, of coaling conditions, and of steel manufacture, as well as an engineering experience of a very wide and varied character. His training has been of such a character that it would give him a first hand knowledge of every detail in connection with the steel business and enable him to appreciate the problems of every department from the office work through the mill and down to the men doing the most menial sort of work around the plant, as he has been taught to work with his hands as well as his head. There are few men in the East who have been more successful in dealing with the varied complex and difficult labor problems that have been arising from time to time than Mr. McDougall. For some years past he has had to face the peculiar conditions of producing more steel than ever before and having fewer men to produce it with.

It was in 1909 that Mr. McDougall first received his appointment as assistant general manager of the Dominion Coal Co. and at that time the labor conditions in connection with the plant were not in a very happy frame as a strike of the workmen had been in progress there for some time. A year later he was successful in closing the protractive stoppage of work at the Spring Hill mines. During the time that Mr. McDougall has been in charge of the management of the Dominion Coal Co. at Glace Bay he has succeeded in raising the production figures of that corporation from 3½ to 5 million tons. Under his direction new coal mines were opened up and as quickly as this was done they were equipped with the most modern machinery. Central power stations were conceived and instaalled and other operations co-ordinated in such a way as to produce the result indicated above. It is also stated that the plans on which Mr. McDougall had been working at Sydney, were such that the production of steel ingots there would have been placed at a figure equal to 35,000 tons per month inside of a few months. Coke ovens of the very latest type and a modern blast furnace are included in the equipment with which he expected to produce the results. The construction of the new plate mill on which a great deal of Government work was to have been done also came very closely under Mr. McDougall's connection, and it is likely that he will have the satisfaction of seeing this work well under way before he leaves that company. So far no announcement has been made by the Dominion Steel Corporation regarding a successor to Mr. McDougall as the general manager of that corporation.

PLATE MIILS ARE THE HOGS OF RAW STEEL AND OTHER INDUSTRIES SUFFER

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., July 24.—It is claimed the interesting discovery has been made that some Canadian steel has been sold in New England at prices far above the Government limits, and for non-essential purposes, while steel made in the United States has been sold in large quantities to Canada at the set limits. It is stated the subject will be taken up with the British Mission.

The rate of steel production was discussed in last report, with particular reference to the rate in June as indicated by the monthly report of the American Iron and Steel Institute. Since then a new complexion has been given the situation by Institute announcing that one of its members understated its June output by 46,516 tons. This means that the rate of steel ingot production in June was at the rate of about 43,500,000 gross tons a year instead of the rate of 42,860,000 tons indicated by the original report. While the change is apparently a slight one, it makes it that June was the best month of the quarter instead of the poorest, also that since the very low production rate of last January there has been a successive improvement each month. Thus there is much better ground for hoping that further increases in the rate will occur later in the year. July and August may show declines, on account of hot weather, but thus far in July the weather has been normally favorable for the season.

Want Old Material

That the full output indicated by the rated capacity of not less than 47,000,000 tons can be attained is, however, quite improbable, by reason of the shortage of scrap and the poor quality of the supplies available, as noted in last report. There are, of course, no prospects of improvement in the scrap supply. The country is being combed for old material but at best such material would be of poor quality. The difficulty arises largely from the nature of industrial operations now being carried on. The railroads are wrecking few cars and locomotives and abandoning smaller quantities of old rails than usual, while there is very little tearing down of old bridges and buildings. Furthermore, there is reason to estimate that more unfinished steel than usual is leaving the country, the scrap arising from the finishing operations being produced abroad instead of at home, and there are practically no importations of scrap. Thus the industry will probably have to peg along at a rate of production under what would occur if conditions as to operations were normal. A slight improvement in steel production may occur if pig iron production increases, though as a rule the steel works want more and better scrap rather than more pig iron.

War Requirements

The rate of production is, however, distinctly better than the rate in 1917 or 1916 because while the output is lower in proportion to capacity there have been material increases in capacity. The rate of steel ingot output of 43.500.000 gross tons a year means an output of finished rolled steel of nearly if not quite 36,000,000 net tons a year, or about 3,000,000 tons a month. In a fresh statement as to steel requirements and supplies the WarIndustriesBoard has now put the war programme as requiring 20,000.000 net tons or perhaps 21,000,000 net tons, during the second half of this year, while it points out that the industry has never produced more than 16,500,000 net tons in a half year. There is, however. considerable basis for hoping that 18,000,000 tons can be produced, possibly more. Steel producers as a class remain chary of accepting the War Industries Board's statement of requirements at face value, having doubts whether the various war activities that call upon the Director of Steel Supply for their various tonnages will really be able to consume the full tonnages within the period set. No one questions that there are precisely formulated requirements totalling 20,000,000 tons the point being how soon the tonnage can actually be fabricated or otherwise utilized.

Plates are being produced at the rate of 500,000 net tons a month, and the major portion of the tonnage is going to the shipbuilding industry, but there is a moderate tonnage of Bessemer steel plates going into carbuilding and other items of essential nature but not absolutely requiring open-hearth stock. Production of shell steel may be estimated at not much under 500,000 tons a month, so that about one-third the total finished rolled steel output is going into these two items. Tin plate, formerly a very small item in point of tonnage, accounts now for more than 150,000 net tons a month. The structural mills are operating very nearly at capacity, with the heavy demand for shapes for shipbuilding and for various large construction jobs of the army, and are perhaps turning out a larger tonnage than ever before.

Where Steel Is Scarce

On account of the erection of so many new plate mills, and for the pushing of all plate mill capacity to the limit, the plate mills are drawing an altogether unprecedented proportion of the total supply of raw steel. The shell steel is alfrom the usual finishing channels, while the tin plate branch is taking more steel than ever and possibly also the structural mills.

With these heavy drains it is readily seen how the other finishing departments, the rod and wire mills, the sheet mills, the merchant pipe mills and the merchant bar mills, are not getting anything like their normal tonnage of crude steel to finish. It is reported that the wire rod mills are restricted to 60 per cent. of their normal full supply. The sheet mills, which the Director of Steel Supply only a few weeks ago desired to be limited to a 75 per cent. operation, are now lined up by a new system of distributing steel to them, to an operation of about 60 per cent. Some merchant bar mills are almost idle, others running only fairly well, depending on the sizes and shapes they are fitted to make.

Thus steel in various finished forms that are not required in particularly large quantities for the direct war work are made very scarce nevertheless, and there is no finished form which is plentiful or even in fair supply.

The total demand for steel that is given no priority or preference, the so-called "unessential" steel, is not estimated at more than 10 per cent. of the total at the outside. If steel were available for this demand it would be steel called Class D, left after the priorities and preferences are taken care of, but there is no such steel, to speak of, and it could not indeed be rolled under the regulations, which require a permit (Class D steel is subject to permit, except fiveton lots) not simply for the shipment of the material but also for the production. If a mill had a surplus of raw steel it would have to hold the steel in ingot form. The War Industries Board has even announced that shell steel discards may not be shipped without permit, though it intimates that the permits may be granted with some freedom.

LIFE IDEALS—The life ideals of a modern educated person cannot be acquired from books or sermons, but must be rediscovered or at least reconstructed by himself, and tested in his experience. The process of acquiring true "weatherproof" ideals involves hard work, devotion, and close attention, like any other human activity.—V. Karapetoff.

THE INDUSTRIAL DEVELOPMENT OF CHATHAM HAS BEEN QUITE MARKED

Although the manufacturers of Chatham, Ont., have not derived much benefit from the large orders for shells that have been, and are still being placed, in the Province of Ontario, the industrial development in the district has been considerable. Only one firm, the Hays Wheel Co., is engaged upon munitions, producing approximately 400 six-inch shells per day. The development in Chatham has been of a general character, incidentally reflecting the favorable situation of this city as an industrial centre. The character of the development and nature of the industries, foreshadows a continuance of prosperity after the war and comparatively little readjustment, as the general line of product manufactured may be said to be of the peace time variety. In other words, the manufacturers will continue in the same line of production after the war as now. By reason of its geographical location, Chatham is favorably situated as an industrial centre. Being only a short distance from Detroit, has been an attraction for American capital, a factor which has been largely instrumental in the development of many Canadian border cities. Chatham is also the centre of a large and prosperous agricultural district; the advantages of this may be seen in the growth of certain industries, particularly the Gray-Campbell Co. carriage works, who make a fine line of buggies, etc., and the Dominion Sugar Co. The last mentioned concern has built a large modern factory costing $1,200,000 for making beet sugar, the beets of course being grown in the vicinity. The well known Chicago firm, the Libby, McNeil & Libby Co., has recently established a large and modern factory in Chatham for manufacturing pickles from vegetables grown in the surrounding district.

Another American concern, the Canadian Des Moines Steel Co., has a plant here for making steel tanks and similar products. The Gray-Dort automobile is made in Chatham and in this connection it is interesting to note that practically all the parts of this car, with the exception of the motor, are made in Canada. At one time, and not very long ago, practically all the parts in the majority of Canadian-built cars were imported from the United States and assembled at the Canadian factory. The Gray-Dort Motors, Ltd., which is operated under the management of Robert and W. M. Gray of Chatham, has extended its activities recently by taking over a factory formerly owned by the Blondy Mfg. Co. for building car bodies.

The output of Gray-Dort cars has been, so far this year, considerably greater than was estimated, a further impetus to Chatham's industrial activity. It is not unlikely that the company's No. 1 plant on Colborne street will have to be extended to take care of the increasing demand for its product.

Among the older concerns connected with the engineering industry in Chatham may be mentioned the Dowsley Spring & Axle Co., Park Bros., McKeough & Trotter, and the Chatham Malleable & Steel Co. The International Harvester Co. have completed the construction of a foundry and other buildings at their plant here.

Natural gas from the Tilbury fields has been an important factor in the development of Chatham as a manufacturing city. Gas is largely used at the local factories for generating steam and also for lighting purposes. The Chatham Electric Co. uses natural gas entirely, generating about 1,600 h.p. by means of gas engines and also using gas under the boilers for its steam plant. Hydro power is installed in Chatham, which is an additional advantage for manufacturers as well as for the citizens as a whole. Cheap power and two railway systems are thus available for manufacturers, both important considerations in the growth of a manufacturing centre. The steady growth of Chatham is reflected in the building construction going on in the city and the increase in building permits.

Gas engines of the four-cylinder double-acting type working on the four-stroke cycle have been made in units up to 4,000 horse-power, and engines on the two-stroke cycle have also been constructed in large numbers and high powers, and have given a satisfactory performance up to 5,000 horse-power. It is estimated that to-day the gas engines at work represented 4,000,000 shaft horsepower. The Diesel engine of the horizontal type, made double-acting with two cranks, a pair of cylinders being arranged tandem on each crank, has been constructed in units up to 4,000 horse-power, and vertical engines single-acting and working on a two-stroke cycle up to 2,500 horse-power. This latter type is that generally preferred in marine work, but for submarines six-cylinder engines of 1,000 horse-power, with a four-stroke cycle and 2,000 horse-power engines with a two-stroke cycle have been used. The fuel consumption of the Diesel engine, assuming fuel oil to have a thermal value of 18,000 B.Th.Us. per lb. works out at .47 lb. per shaft horse-power per hour, giving an efficiency of about 30 per cent. as compared with that of a steam engine equipment, in which the coal consumption was 1.5 lb. per indicated horsepower per hour, which was 10 per cent.

SCREENING THE SEADOGS

Nowhere has the art of camouflage been more successfully used than in the spectacular attack on the U-Boat bases of Zeebrugge and Ostend. Under a screen of smoke the ships of the fleet were enabled to get close enough to bottle up the U-Boats. This photograph was taken on board the Iris, one of the covering ships used in the Zeebrugge raid. One of the officers is turning on the tap to release the smoke that made a screen like a mist between the attacking ships of the fleet and the land batteries.

Promotion the Real Way to Keep Employees

The Employment Department of Any Organization Should Seek to Pass on Only the Most Suitable Applicants to Departments Where Openings May Have Occurred—How the Work Can be Co-ordinated

By M. H. POTTER

THE raising of the standard of efficiency of the working force, individually and as a whole, in order that the purchasing power of the wage-dollar may be increased, is the broad function of the employment department. The employment department is the department whose duty it is to develop the efficiency of the workers, directly or indirectly, and to bring about a condition in which the individual employee will render as nearly as possible 100 per cent. to his employer.

Personal efficiency is composed of various proportions of brains, health, instruction, loyalty, enthusiasm, ambition, ability to co-operate, personality and character. This purpose can best be served through a centralized employment department, under a manager reporting directly to the general manager of the company—a department composed of four divisions, as follows: first, the employment division, which assumes the task of selecting and engaging the help; second, the medical division, whose function, of course, is to see to the physical health of the employees; third, the instruction division, through which the employees are given the opportunity to increase their special ability and training; fourth, the welfare division, whose purpose is to create a favorable mental background for the workers. Let us consider these divisions in order.

Employment Division

It is the duty of the manager of the employment division to keep in touch with the sources of labor supply and engage workers best qualified to fill the vacancies occuring in the organization. These vacancies are reported to it on labor requisitions received from the executives of the operating departments. When a mechanical engineer constructs a machine, he naturally exercises the greatest care as to the quality of the material he puts into it. Similarly, when a human engineer is constantly at work building up an efficient working force, he must use the best care and discrimination in choosing the units which are to comprise it. Subsequent training is indispensable and frequently is instrumental in transforming unpromising employees into efficient workers; but the value of the training is greatly increased when it is applied to responsive material and the result is much better.

The employment office file in which are classified by kinds of work the application blank filled out by individuals who have called seeking employment, is the most fruitful source of supply. Quite naturally, for every position that is open there are several applicants. Only one can be selected for the particular vacancy, but among the others are invariably several who are well qualified for consideration when other vacancies occur.

Another source of supply is that represented by the payroll. Whenever a position of any importance is to be filled, by going through the present organization there will be found persons who can be promoted to that position.

Of course, splendid material for stenographic and clerical work can usually be obtained from the high schools, the principals of which are naturally interested in placing their graduates. Similar material of a clerical nature can often be obtained from the various typewriting agencies who, in a similar way, are interested in placing their clients.

As a rule there are several employment bureaus of the city always at service, but owing to the nature of their clientele, much undesirable material passes through their doors. Too many bureaus of this kind operate in a mechanical way, without giving the vocational guidance to which applicants are entitled. Too frequently they feel their duty is done when they give an applicant a letter of introduction to an employer regardless of whether or not he is particularly equipped for the employer's service or whether he is accepted.

A vast quantity of material is available through the classified advertising columns of the newspapers. Advertising of this kind naturally brings a certain proportion of applicants who are hopelessly unfit, but these can be rapidly eliminated and desirable applicants retained for more complete analysis and examination. Except where immediate action is needed, the blind advertisement is more satisfactory than the advertisement which mentions the employer's name. Blind advertisements automatically eliminates much of the hopeless material and enable the manager of the employment division to exercise preliminary judgment by analyzing the letters received from the applicants.

Applicants for positions are shown into an anteroom, where those who are obviously undesirable are weeded out. Those who deserve further consideration are requested to fill out application blanks which, when complete, show their age, their previous business experience, the names of their previous employers, the length of their service and their reasons for leaving those employers, their previous salary and the salary expected, and the names of references. Each of these blanks is delivered to the manager of the employment division, who thus has a chance to analyze each applicant's previous experience before the applicant himself is shown into the managers 'inner office.

Doubtless each employment manager has his own particular system of sizing up applicants. Immediately after the interview or during it, the manager of the employment division fills out one of our analysis cards with which it is possible to mentally reconstruct the applicant at any future time, in order to consider him for any later vacancy, if he is not employed immediately. The analysis cards contain eight divisions, as follows:

Personality.
Build.

English.
Type of mind.
Executive.
Detail.
Promotive.
Mechanical.
Analytical.
Appearance.
Mentality.
Super alert.
Alert.
Average.
Slow.
Dull.
Initiative.
Remarks.

The phrases explain themselves. Let us assume that a certain applicant has called at the employment office, has filled out an application blank, has been interviewed by the manager of the employment division, and has passed satisfactorily. The applicant is then conducted to the executive of the operating department for whom he has been secured, and is interviewed by that executive, whose decision is final. If the applicant similarly satisfies the operating executive, he is then sent back to the employment division and examined by the physician in the medical division. If the physican gives him a clean bill of health, the employee s then told where and when to report by the employment division, is given final instructions, and is made to feel as much at home as possible.

Letters of inquiry are then sent to the persons named as references by the applicant. The value of these references is moral rather than practical, as few employers will voluntarily stand in the way of an ex-employe of theirs securing employment elsewhere.

If the applicant should be rejected by the executive in the operating department, he is similarly sent back to the employment division, where he is either placed elsewhere in the organization or told that his aplication will be considered snould any other vacancies arise for which he is qualified. Occasionally the judgment of the manager of the employment division and the operating executive will differ in this way; yet the employment department never makes an issue of such a case or endeavors to force an employee upon an unwilling executive. Such an issue would not only be bound to arouse antagonism on the part of the operating executive, which in turn would be fatal to harmonious and efficient work on the part of the employment department, but it would also fail of its purpose, inasmuch as whether or not the operating executive has the legislative activity to reject an applicant recommended by the employment department, he at least has the ability to make things so unpleasant for the new employee that he would willingly resign.

However, the engaging of help is not the complete function of the employment department. This division similarly acts as a clearing-house of labor between department and department and makes possible a condition in which one department may be laying off help while another department of the same company is engaging help of the same character. It is obligatory upon the employment division also to keep as accurate a report as possible of the performance of employers and to transfer those who are misplaced to other positions for which they are better fitted by temperament. An employee who works at his job because he is fitted for it, because he enjoys it, and therefore, puts enthusiasm into his work, is worth far more to his employer than the worker who works indifferently at his job only because he is paid for it and who quits as on principle immediately on the stroke of the bell.

Medical Division

The work of this division dovetails somewhat with the work of the employment division. The hospital consists of a waiting room, an outer office, where bandages are applied and minor injuries treated by the orderlies, and the inner office, where the doctor holds his examinations. An orderly is in attendance both day and night and a physician is in attendance every afternoon. Two nurses are constantly in attendance at the women's hospital during the day and night.

Instruction Division

Three good-sized rooms, well-lighted, comprise the quarters of the instruction division. Instruction is the process of training a new employee capable of delivering perhaps 10 per cent. service into a trained worker capable of delivering 90 per cent. service or better. Methods of this training differ with different concerns. Some concerns, owing to the nature of their work, find it best to maintain schools, under salaried teachers, for this purpose. Other concerns have their instruction work done departmentally by persons designated to that task or even by foremen and fellow employees. Where the instruction work is done in this way, the employment department should be an interested party. It should either exercise direct control or a strong advisory influence.

Welfare Division

The work of this division has direct reference to the state of mind of the employee. This division of the work is founded on the certainty that an employe who is happy and satisfied and free from anxiety and who works under favorable physical conditions will do better work and more of it than an employe who is dissatisfied, fearful of the future, and who does his work in an unfavorable physical environment. For want of a better name, this division of the work is called "welfare work."

Industry is coming to regard personnel as one of the big factors to be considered in every undertaking, and if it is so, then the work of the welfare department is an economic necessity. But this work must be conducted along economic lines, as every other department is conducted, every dollar spent on it must yield 100 cents in return.

It is the duty of the welfare division to go after the fundamental things first. The question of wages and hours of labor are, of course, such broad subjects that all the administrative officials of the company collaborate on them. The welfare division, however, gives constant attention to matters of almost equal significance, the conditions under which the employes work—light, air, safety devices, sanitary arrangements. It is not reasonable to expect an employe to reach his or her place of work in the willingnes, if he has to pass through the garnut of dark, congested coat rooms and either climb several flights of stairs or wait his turn to get into an elevator together with a crowd of other workers, al as vexed as he. To bring the individual employe to the frame of mind where he is able to deliver efficient services, it is obvious that the employer, through the welfare division, should arrange for those physical surroundings which will breed self-respect, cheerfulness and confidence.

Restaurants are maintained, where the employes can secure their meals at minimum rates without going outside. Restaurants of this kind are largely self-supporting. Good food makes for good health, especially when served under agreeable conditions, and the lunch hour is the time when the employes meet socially.

In addition a recreation room where those who wish to talk and engage in more active persuits are permitted to make as much noise as they wish. It has been found that rest rooms, smoking rooms and recreation rooms justify their expense many times over bby keeping the employes in the building during the noon hour.

In General

By the very nature of its field, the employment department must be a service department. It is not an operating department, but it should work hand-in-glove with the genuinely sincere way to increase their own efficiency, through increasing the efficiency of their employes. It should not seek credit for what it does, only results—onwhich in the end is must stand or fall. Many of its achievements for the improvement of the working force must beb accomplished indirectly, by counsel and advice, and the credit oftentimes must go elsewhere. If by its activity, either direct or indirect, there results permanent economic advantage to the company through the improvement of its human relations, the employment department will take its place in the organization as one of the productive departments.

The Plan of Promotion

An adequate system of promotion is the solution not only of holding employes in an organization, but also of the employment problem.

There is to-day much emphasis upon the proper selection of employees, and many and elaborate systems have been undertaken for a scientific placement. These are not in army wise to be criticized, for the selection of the indivii-duals comprising any organization is important, and any plan that will cause the employment manager to plan his duties carefully and to give each decision on the fortunes of others careful consideration is to be commended. It must beb realized, however, that even more important is holding and helping these employees after they have been selected, and providing an adequate systematized plan of advancement for them. It has been so figured in some plants that efficient placement becomes almost automatic, and a supply of desirable applicants for any position is constantly available. The following three points are important:

1. The necessity of attracting desirable applicants.
2. The necessity of holding, fitting and promoting those already employed.
3. The interdependence of these two.

This plan of promotion considers each employee as occupying three positions in the organization, and considers these three positions as constantly changing in an upward spiral, as the man is promoted from the lowest position that he occupies. The three positions are as follows: first, and lowest, the position that the man has last occupied in the organization; second, the position that the man is occupying at present in the organization; third, and highest, the position that the man will next ocupy. In the first position the worker ocupies the place of the teacher, this position being at the time occupied by two other men, that is, by the worker doing the work, who receives little or no instruction in the duties of that position except in an emergency, and by the worker below who is learning the work. In the second position the worker is actually in charge of the work, and is constantly also the teacher of the man next below him, who will next occupy the position. He is also, in emergencies, a learner of the duties of his present position from the man above him. In the third position the worker occupies the place of the learner, and is being constantly instructed by the man in the duties of the position immediately above.

Naturally a plan like this demands a close co-ordination of all positions. This is provided for through the master promotion chart. This chart is in the hands of the man in charge of promotion. It consists of a schematic arrangement of all positions in the organization, so arranged as to provide for lines of most rapid advancement, along the various functions and subfunctions, under which the measured functional management by which it works. The great advantage of such a chart is that it makes possible visualizing the complete problem of the organization's needs in teaching and preparing its members. The direct product of this is that the man in charge of promotion sees clearly the needs and the means of filling them, the demand and the supply. The important by-product is the gradual evolution of permanent, rapid, direct paths of promotion. Another by-product of this chart is the fact that the promotion head, the promotion manager, or chief of promotion, as he has been variously called, can arrange for shifting or transferring the worker easily, if he sees that he has been improperly placed, or, if he develops abilities along some unexpected line. This is often the case under this type of management where there is great opportunity for the development of talent, as well as apparent, abilities.

Upon the promotion charts the records of each and every member of the organization are separately kept. When a worker becomes a member of the organization he is called into the department in charge of advancement or promotion, and given one of these charts. Upon it is shown his present position, and he and the man in charge outline together his possible and probable line of advancement. The projected line of promotion is outlined in green, and upon it are placed the dates at which it is hoped he may reach the various stages of advancement. At set times the worker and the promotion chief, or one of his helpers, meet, and the line of actual progress of advancement of the worker is traced upon the map in red, with the dates achieving the various positions. The two then consult as to existing conditions, the special reading and studying necessary for fitting for the new positions, possible changes, or betterments.

The ultimate success of this plan depends upon the principles that underly it, giving every man a square deal, a maximum chance for cooperation, advancement and prosperity, in other words, the opportunity for simultaneous individual and social development.

ROMANCE OF GAS BY-PRODUCTS

By I. T. H.

There is nothing more remarkable in the fairy tales of industry than the manner in which the Cinderellas have been taken from the kitchen, so to speak, and given precedence over their step sisters. In soap-making, for instance, at one time the soap was the only thing that mattered and the glycerine which was produced at the same time from the fats and oils was run down the drain. Now the soap works are busy night and day primarily making glycerine for munitions, and the soap is almost a waste product. It has been very similar in gas making. At one time the gas liquor with its evil smell was merely a nuisance, now nearly all our ammonia for fertilizing the fields, a large part of our sulphur, and the cyanides for the extraction of gold are obtained from it. Not long ago the recovery of tar from the bottoms of pits and canals, where it had been run to get rid of, was quite a business, but tar now gives us the bases of our aniline colors, many of our most valuable medicines, and even perfume; while the tar oil becomes at the touch of the chemist's wand, lyddite, trinitro-toluol, and similar substances for the terrible high explosives for our shells, mines, and torpedoes. So valuable have the benzol and toluol become that the tar, however carefully it be treated, does not supply enough, and processes have been at work for some time to recover the comparatively small quantities that exist in coal gas itself. So far these methods have been only partially successful. According to a new process, it will be possible to secure about two gallons of benzol and a tenth of that quantity of toluol from every 1,000 cubic feet of gas. The method is simplicity itself. The gas passes through a tower filled with lumps of porous material saturated with oil, which absorbs the whole of the benzol and toluol, and then by the simple application of steam separates them; they float on the top of the condensed water, and can be drawn off ready for use, requiring only to be separated from one another by distillation. The discovery will add very greatly to our resources not only for making high explosives during the war, but also for our rapidly growing aniline dye industry in both war and peace; and later, when our big guns are at rest, it will provide a source of fuel for our motor vehicles.

The exportation of refrigerated beef is one of the important features of the Brazilian export trade during the past few years. From 1914, the first year of the war, the exports have increased from 1 ton to 66,452 tons in 1917. Brazil is unquestionably destined to become one of the great meat-producing countries of the world, and not only do its present exports bear out this fact, but the establishment of large packing plants, many of the mbeing financed by large American firms, shows clearly that the future prospects of the country as a producer of fresh meat are very promising. More than 50,000 tons, or nearly 80 per cent. of the total of refrigerated beef, went to Italy; Egypt took nearly 6,000 tons, France over 5,000 tons, and Great Britain nearly 4,000.

Gage glasses are very susceptible to surface abrasions, even so minute as to be unobservable. If one receives the slightest scratch inside or out, it should not be used, and in handling or keeping them in stock, no metal of any nature should be allowed to come in contact with them. They are particularly liable to break if iron or steel touches them and should never be laid even temporarily with tools, as is frequently done.

Making Shrapnel and High Explosive Shell Bars

Weight and Balance of a Shell Made From Solid Bar Steadier Than That of a Cast Shell in Flight Through the Air

By W. S. Standiford

IMMENSE quantities of shrapnel and high-explosive shells have been made in U.S. for the Allies and since the United States has joined in the conflict considerable amounts of munitions are required by the American Forces; as steel bars are the basis from which the shells are manufactured, the design of the rolls, their proper adjustment and handling should be subjects of much interest.

At first thought one might suggest that the shells be manufactured faster and better from castings containing the chamber for powder and bullets, thus leaving very little metal to remove in the machining processes, as contrasted to the existing practice of punching a hole in a solid steel blank and then finishing the interior and exterior. But castings cannot be used in this case for cast metal usually contains airholes, making it dangerous material for shells; were cast shells used, there would be danger of their bursting in the guns.

Another reason is, that the weight and balance of a shell made from a solid bar has a steadier flight through the air than one made from a casting, since in the latter, the heavier ingredients of the steel settle to the bottom during the cooling, making certain parts of the walls heavier than others, which obviously disturbs its balance during flight. Steel bars as munition material have the carbon and other ingredients equally distributed, for the rolling process mixes them equally, making the metal fibrous in character.

The size of the round bar is 3½ inches in diameter; this is the size used to make the 18 pound projectile used in British field guns, and it will be noted that sufficient metal is allowed on the above sized bar to permit of the machining operations. In the first illustration, are represented the roughing rolls, the latter being three-high; which design rapidly reduces the steel as compared with the two-high ones; quick reduction of the hot bars at the start is most important, for the metal must be worked while it is at a high heat, this makes it fibrous, which is a desirable quality, since this condition makes for strength in iron and steel; the roughing rolls contain two boxes and two edging passes; the others being put in on an angle.

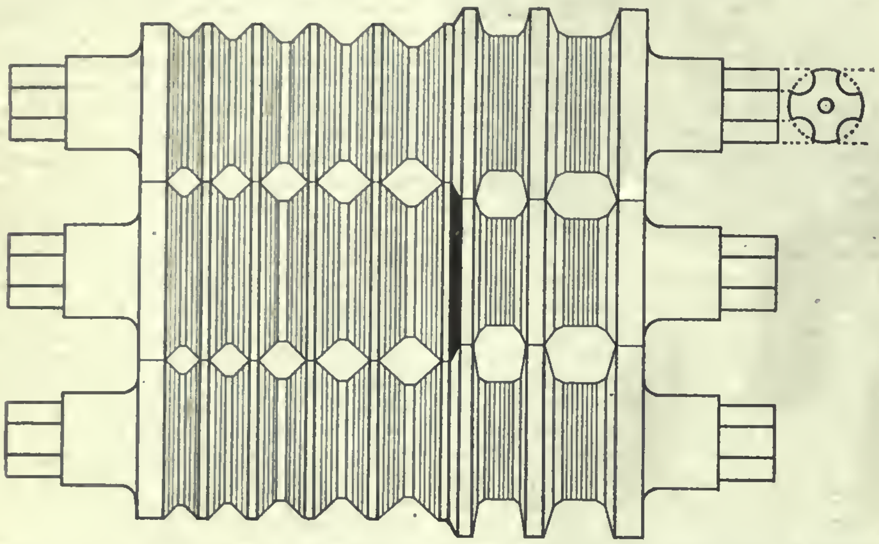

FIG. 1—ILLUSTRATES BOX AND EDGING PASS ROUGHING ROLLS. THE DEEPEST PASS IN THE BOTTOM ROLL BEING WHERE THE STEEL BILLET IS ENTERED FROM THE FURNACE. THIS STYLE OF GROOVE REDUCES THE METAL VERY RAPIDLY, THE VIOLENT CHANGE IN SECTION FROM THE BOX AND EDGING PASSES TO THE SQUARE ONES THE STEEL FIBROUS IN NATURE WHICH IS A HIGHLY DESIRABLE QUALITY IN IRON AND STEEL.

Box and edging passes, by their shape, allow heavy drafts to be used, which is exerted upon the tops and bottoms of the bars, there being no work done on the sides. The heated metal from the furnace goes into the deepest box pass, it is then pushed into the next largest one between the middle and top rolls; being now turned over on its side, it goes through the edging pass in the bottom roll and is repeated through the top edging pass.

The steel in the shape of a long square bar is now ready to be rolled in the angle shaped passes which next engage our attention; these have an angle of 95 deg. and by their position in the rolls, work the bars mostly on the top and bottom corners—the corners at the sides have no work done on them. The bar goes through the angle passes alternately, until it is reduced to four inches in diameter; then it is ready for rolling in the hand rounds or finishing rolls which appear in the second illustration.

Any person looking at a set of hand round rolls in the housings or a drawing of them would wonder how they could make a round bar, as the grooves appear to have an oval shape instead of a circular one, but this is a case where appearances are deceptive; the grooves are put in by means of round steel plugs, which are ground after hardening, as the latter throws them out of true circular form.

Each roll contains one-half of the grooves for making various sized round bars; after the round groove is put in by means of the plug, the sides near the top are cut away at an angle by using another tool, the reason for this being that it prevents a long ridge or fin from forming on each side of the

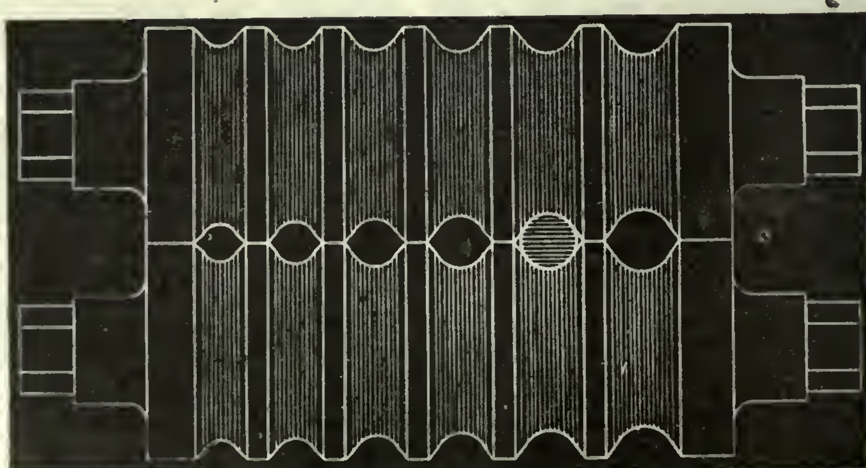

FIG. 2—SHOWS THE APPEARANCE OF THE PASSES IN THE FINISHERS. THESE PASSES IN THE ROLLS APPEAR ANYTHING BUT ROUND, THE CUTAWAY PARTS OF EACH PASS BEING NECESSARY TO LET THE BAR LEAVE ROLLS EASILY WITHOUT TEARING IT AT THE JOINTS OF THE ROLLS. THE SHADED SECTION OF A BAR IN THE FINISHING PASS SHOWS HOW A BAR LOOKS IN THE OVAL-SHAPED PASS.

bar at the joint of the rolls. The following description of the rolling of a bar will show how it is made round instead of oval. The four inch square bar from the roughing rolls is sent once through the 3¾ inch pass, it is then turned over at a right angle to its previous position and is pushed into the 3½ inch finishing pass; as the bar from the 3¾ inch groove goes through the 3½ inch one, the metal spreads out in the extended sides and is about 7/16 of an inch wider at the sides as a result.

The part that touched the top and bottom of the pass being the correct size, it is then again turned over at a right angle so that the wide part will touch the top and bottom of the grooves, and rolled again; the part of the bar rolled to the finished size now faces the cut away portions of the pass, but does not touch it, therefore it keeps the right diameter while the wide part of the bar is being rolled to size. This is followed by again turning it to a right angle to its previous position and giving it its final rolling; the shaded outline of the finished bar indicates that the total width of the cut away clearance part of the pass is slight. In buying steel for shrapnel shells, the requirements of the purchaser are most exacting, with the result that the manufacture of shrapnel and high-explosive bars is costly.

As an example, bars for high-explosive shells call for a discard of 40 per cent. of the ingot; bars for shrapnel, 30 per cent., and ordinary steel bars about 15 per cent. The bars for high-explosives and shrapnel shells are subjected to a rigid inspection, the demand for a large ingot waste by the purchaser is due to the latter's desire to secure a metal free from airholes and segregation, which would interfere with the proper working of the shells in the guns.

THE PRODUCTION OF LIQUID AMMONIA

By Mark Meredith

Until the beginning of the war Holland was dependent for its supply of liquid ammonia upon England, Germany and more particularly Belgium. At the commencement of 1915 no liquid ammonia was to be had in Holland, as not only the ammonia itself, but also the steel cylinders for containing it, had been commandeered in the belligerent countries, or declared contrabrand of war. This caused much trouble to the industries making use of low temperatures. Calculation showed that the total annual consumption of Holland would amount to something like 27,000 kilogrammes.

At the Arnheim gasworks all the ammoniacal liquor produced was generally converted into pure concentrated ammonia solution: but during the war the high prices of sulphate, and the national need for artificial fertilisers, led to part of the ammonia being sent out as sulphate. The ammonia as driven off is saturated with water; but it is important now to obtain it as dry as possible, to ensure the safe working of refrigerating machines. The restrictions in this connection are therefore of increasing severity. Whereas some twenty years ago 0.9 to 1 per cent of water was permitted in liquified ammonia, the maximum now allowed has been lowered to 0.4 to 0.5 per cent. The drying properties of chloride of lime cannot be made use of, as it combines with ammonia. Caustic soda too is valuable in these days, so there remains only as an available drying agent burnt lime. This, however, has insufficient drying effect, except under pressure. With the pressure at normal, the lime generally left 0.9 to 1 per cent of water in the gas. The most effective means of producing totally anhydrous ammonia—with 0.05 per cent of water—is by evaporating the liquified ammonia, and subsequent reliquifying of this volatilised first product.

At the Arnheim works efforts have been made to eliminate the greater part of the water by cooling. To the current of wet ammonia gas, there is added liquified ammonia at a regular temperature. By the evaporation of the liquified gas the temperature falls as low as 15 deg. C. Thus the water is condensed, after which the gas is led through the drying apparatus. The condensed water is of course saturated with ammonia and leaves the compression plant through a syphon. The amount of liquid ammonia, about 7 per cent of the total bulk produced, is naturally not lost, as it is liquified again. It is taken from cylinders and not from the general storage holder, to permit of control of the quantity used. After this treatment the gas passes through two towers filled with lumps of burnt lime; the inlet being at the upper side, the outlet at the under side. Provision is made for subsequent treatment of the gas with caustic soda lumps in a separate tower.

After these processes the gas passes to a large storage holder, from which it goes to compressing plant very similar to that in use for the manufacture of ice, except that there is no brass and the compression cylinder stands in circulating cooling water. Mineral oil is used for lubrication, an oil-separator being placed after the compressor for removing the surplus oil. In spite of this cooling, the ammonia gas when compressed at from 7 to 10 atmospheres becomes warm. It is condensed in a large cooling coil, and then collected in a storage receiver of about 70 gallons capacity, thereafter being emptied from this into the steel bottles.

On the pressure side of the compressor, and above the cooling coil, there is a blow-off tap. The permanent gases, and more especially the air, which accompany the ammoniacal gas from the stills are blown off during the working, and conducted through water for the retention of the ammonia. From the storage receiver the ammonia is charged into steel bottles, after these have all been emptied by a small pump operated by the gas engine which drives the compressor. The chemical and physical properties of gaseous and liquified ammonia are well known; but there is one peculiarity which may be referred to—the high expansion co-efficient of the liquid. At ordinary temperatures this expansion is less marked, but at slightly raised temperatures the increase becomes very marked gramms.

At 10.0° C.	pressure is	88.2 lb.	per sq. in.
" 50.0° C.	" "	294.0 lb.	"
" 65.7° C.	" "	455.7 lb.	"
" 67.7° C.	" "	860.0 lb.	"

Thus, for a rise of temperature of only 2 degrees C., the pressure is almost doubled. The filling of the bottles therefore needs special care, for when the expansion is not taken into account an explosion of the bottle is to be feared. The delivery of high ammonia during the first year amounted to 40,000 kilogrammes.

EASTERN SPRUCE FOR AEROPLANES

So great is the demand for airplane spruce by the Allies that eastern as well as Sitka spruce is now being used. Canada has large resources of eastern spruce, which has hitherto been used mostly for the manufacture of pulp, paper and lumber, and the British War Mission is at present trying to secure in eastern Canada as large an amount as possible of the grades suitable for airplane manufacture.

Eastern spruce has for some time been used for airplane construction in the United States, although only a very small percentage of this timber is sufficiently clear for this purpose. Tests made by the United States and Canadian governments show that where material of suitable quality can be found, this species serves admirably for airplane construction and may be expected to supplement the supplies of Sitka spruce from the Pacific Coast, which are only now beginning to approach adequate proportions.

The timber for use in airplanes has to be sawed parallel to the bark, instead of parallel to the axis of the log, as is done for lumber. In this way, straight-grained boards are obtained, having the highest possible percentage of material free from knots and possessing a maximum of strength.

ESTHETIC

Two fair munition workers were discussing their personal affairs.

"Got a chap yet, Liz?" enquired one.

"Yes; and he's a regular toff. He's manager at —"

"You don't say so! Why, they tell me he's real refined."

"Rather! Why, he took me to a restaurant last week, and when we had coffee he poured it into a saucer to cool it, but he didn't blow it like common people would—he fanned it with his hat."

The Duty of the Employer in the Reconstruction of the Crippled Soldier

In the Past the Pension System Proved a Failure Constructively — The Only Compensation For Physical Disability is Rehabilitation For Self-support

By Douglas C. McMurtrie,

Director Red Cross Institute for Crippled and Disabled Men, New York City.

SOON after the outbreak of hostilities the European countries began the establishment of vocational training schools for the rehabilitation of disabled soldiers. They had both the humanitarian aim of restoring crippled men to the greatest possible degree and the economic aim of sparing the community the burden of unproductivity on the part of thousands of its best citizens. The movement had its inception with Mayor Edouard Herriot of the city of Lyons, France, who found it difficult to reconcile the desperate need for labor in the factories and munition works while men who had lost an arm or a leg but were otherwise strong and well were idling their time in the public squares. He therefore induced the municipal council to open an industrial school for war cripples which has proved the example and inspiration for hundreds of similar schools since founded throughout France, Italy, Germany, Great Britain and Canada.

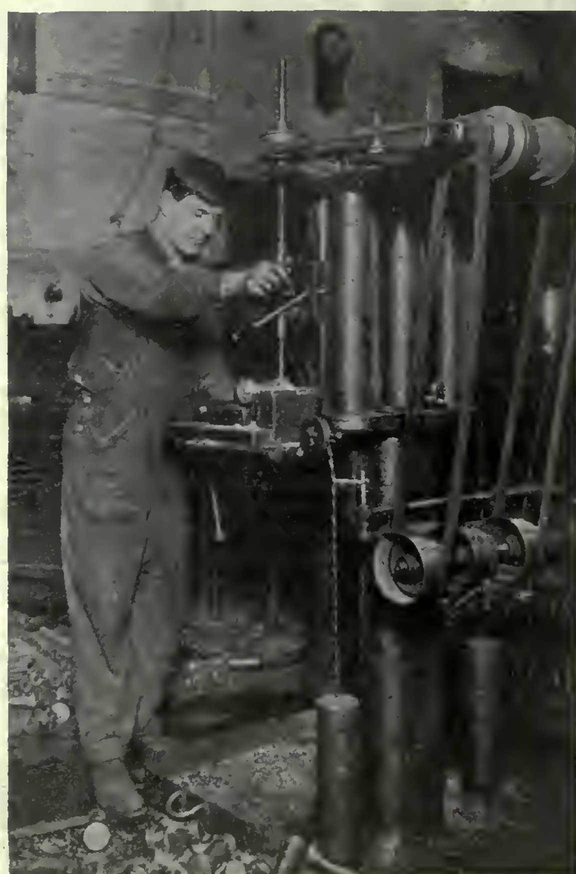
The disability of some crippled soldiers is no bar to returning to their former trade, but the injuries of many disqualify them from pursuing again their past occupation. The schools of training prepare these men for some work in which their physical handicap will not materially interfere with theid production.

Influence of Previous Training

The education of the adult is made up largely of his working experience. The groundwork of training in his past occupation must, under no circumstances be abandoned. The new trade must be related to the former or be, perhaps, an extension or specialization of it. For example, a man who had done manual work in the building trades may be instruction in architectural drafting and the interpretation of plans be fitted for a foreman's job, in which the lack of an arm would not prove a serious handicap. A trainman who had lost a leg might wisely be prepared as a telegrapher, so that he could go back to railroad work, with the practice of which he is already familiar.

Whatever training is given must be thorough, for an adult canot be sent out to employment on the same basis as a boy apprentice. He must be adequately prepared for the work he is to undertake.

The one-armed soldier is equipped witn working appliances which have supplanted the old familiar artificial limb. The new appliances are designed with a practical aim only in view; they vary according to the trade in which the individual is to engage. For example, the appliance for a machinist would be quite different from that with which a wood turner would be provided. Some appliances have attached to the stump a chuck in which various tools or hooks can interchangeably be held. The wearer uses these devices only while at work; for evenings and holidays he is provided with a "dress arm" which is made in imitation of the lost member.



LEARNING THE OPERATION OF A DRILL PRESS.

Avoid Temporary Dependence

An important factor in the success of re-educational work is an early start, so that the disabled man shall have no chance to go out unemployed into the community. In even a short period of exposure to the sentimental sympathy of family and friends his "will to work" is so broken down that it becomes difficult again to restore him to a stand of independence and ambition. For this reason therefore, the plan for his future is made at as early a date as his physical condition admits, and training is actually under way before the patient is out of the hospital.

In the readjustment of the crippled soldier to civilian life, his placement in employment is a matter of the greatest moment. In this field the employer has a very definite responsibility.

But the employer's duty is not entirely obvious. It is, on the contrary, almost diametrically opposite to what one might superficially infer it to be. The duty is not to "take care of" from patriotic motives a given number of disabled men, finding for them any odd jobs which are available, and putting the ex-soldiers in them without much regard to whether they can earn the wages paid or not.

Yet this method is all too common. A local committee of employers will deliberate about as follows: "Here are a dozen crippled soldiers for whom we must find jobs. Jones, you have a large factory; you should be able to take care of six of them. Brown, can you not find places for four of them in your warehouse? And Smith, you ought to place at least a couple in your store."

Such a procedure cannot have other than pernicious results. In the first years of war the spirit of patriotism runs high, but experience has shown that men placed on this basis alone find themselves out of a job after the war has been over several years, or in fact, after it has been in progress for a considerable period of time.

Charity Jobs Deteriorating

A second weakness in this method is that a man who is patronized by giving him a charity job comes to expect as a right such semi-gratuitous support. Such a situation breaks down rather than builds up character, and makes the man progressively a weaker rather than a stronger member of the community. We must not do our returned men such injury.

The third difficulty is that such a system does not take into account the man's future. Casual placement means employment either in a makeshift job as watchman or elevator operator such as we should certainly not offer our disabled

COACH BUILDING IN THE RAILROAD SHOPS.

men except as a last resort—or in a job beyond the man, one in which, on the cold-blooded considerations of product and wages, he cannot hold his own. Jobs of the first type have for the worker a future of monotony and discouragement. Jobs of the second type are frequently disastrous, for in them a man, instead of becoming steadily more competent and building up confidence in himself, stands still as regards improvement and loses confidence every day. When he is dropped or goes to some other employment, the job will have had for him no permanent benefit.

Twelve men sent to twelve jobs may all be seriously misplaced, while the same twelve placed with thought and wisdom and differently assigned to the same twelve jobs may be ideally located. If normal workers require expert and careful placement, crippled candidates for employment require it even more.

Employer's Duty

The positive aspect of the employer's duty is to find for the disabled man a constructive job which he can hold on the basis of competency alone. In such a job he can be self-respecting, be happy, and look forward to a future. This is the definite patriotic duty. It is not so easy of execution as telling a superintendent to take care of four men, but there is infinitely more satisfaction to the employer in the results, and infinitely greater advantage to the employee. And it is entirely practical, even in dealing with seriously disabled men.

A cripple is only debarred by his disability from performing certain operations. In the operations which he can perform, the disabled man will be just as efficient as his non-handicapped colleague, or more so. In the multiplicity or modern industrial processes it is quite possible to find jobs not requiring the operations from which any given type of cripples are debarred. For such jobs as they can fill the cripple should be given preference.

Thousands of cripples are now holding important jobs in the industrial world. But they are men of exceptional character and initiative and have, in general, made their way in spite of employers rather than because of them. Too many employers are ready to give the cripple alms, but not willing to expend the thought necessary to place him in a suitable job. This attitude has helped to make many cripples dependent. With our new responsibilities to the men disabled in fighting for us, the point of view must certainly be changed. What some cripples have done, other cripples can do—if only given an even chance.

The industrial cripple should be considered as well as the military cripple. for in these days of national demand for the greatest possible output there should not be left idle any men who can be made into productive workers.

With thoughtful placement effort, many men can be employed directly on the basis of their past experience. With the disabled soldiers who profit by the training facilities the Government will provide, the task should be even easier.

A Patriotic Duty

This, then, constitutes the charge of patriotic duty upon the employer:

To study the jobs under his jurisdiction to determine what ones might be satisfactorily held by cripples. To give the cripples preference for these jobs. To consider thoughtfully the applications of disabled men for employment, bearing in mind the importance of utilizing to as great an extent as possible labor which would otherwise be unproductive. To do the returned soldier the honor of offering him real employment, rather than proffering him the ignominy of a charity job.

If the employer will do this, it will be a great factor in making the complete elimination of the dependent cripple a real and inspiring possibility.

Maintaining a constant water level irrespective of the rate of evaporation affords considerable protection to the boiler, inasmuch as the danger of low water is removed, and the danger of injuring the engine or other steam-using machine, due to slugs of water being carried over from the boiler is entirely eliminated.

A POINT deserving of attention from brass founders is the marking of runners with a certain mark for each class and mixture of metal. In some cases the molder can put a certain mark with his tools, but if a stamp be used to denote each particular mixture, the men who chip off the runners can easily distinguish what class of metal it is made from, and the scrap gates can be kept quite separate.

RECEIVING INSTRUCTION IN THE MACHINISTS' TRADE.

Good Progress Made at Dominion's New Plant

Actual Building Operations Were Under Way Before the Shops Were Completed—Excellent Progress Has Been Made on the Work

GOOD progress is being made in the construction of the new plant for the Dominion Shipbuilding Co. at the foot of Bathurst street, Toronto, and actual shipbuilding operations are under way although the shops are not completed.

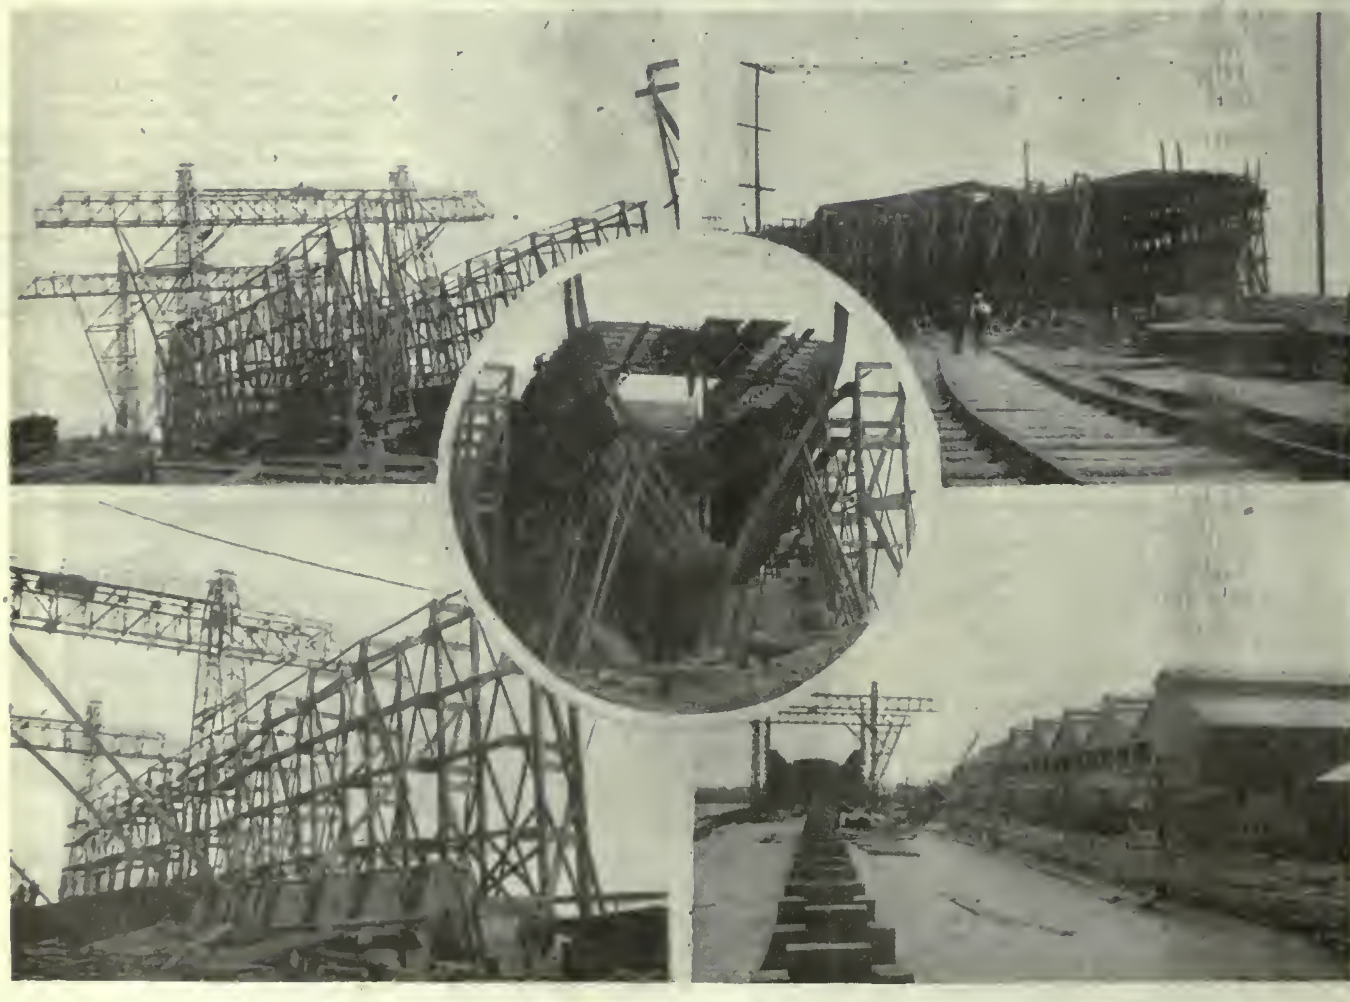
The main building is 485 feet by 210 feet divided into two sections, the first section comprising the plate shop and the second section the joiners shop with mould loft above. The power plant is also included in the main building while the furnaces are in an annex adjoining the eastern end of the plate shop.

The building is of steel construction with steel roof trusses while the outside walls are fireproof, being made of steel mesh treaded with "Gunite." All partitions walls are of hollow tile construction. The windows have Finestra steel sash. The roof of the plate shop is corrugated iron while the roof over the mould loft is made up of boarding covered with built-up roofing material. The steel work was supplied and erected by the Dominion Bridge Co.

The furnaces for heating angles and ship shapes etc., which are oil fired, were designed by John Main and installed by the Canadian Incinerator Co., Toronto. A considerable section of the floor in one bay of the main building is laid out for working up angles and other shapes. The other four bays of the plate shop each have a "Northern" electrically operated, overhead, travelling, 3 ton crane, while the equipment consists generally of punching and shearing machinery, etc., for fabricating plates, etc., for the ships under construction. All the machines are motor driven. Some delay has been experienced in obtaining the woodworking machinery, otherwise the joiners, shop would now be in operation.

The foundations have been laid and steel work has been erected for another building which will be 325 feet by 155 feet and will take in the machine, blacksmith, pipe and electrical shops. The construction of the second building will be similar to the first. In order to carry on the construction of the ships, while the new shops are being erected temporary woodworking and blacksmith shops and stores, etc., are being used. It is expected that the new plant will be completed and in operation this Fall. The site of the plant covers about 16 acres and is practically all made land. The concrete retaining walls were constructed and the site made by the Toronto Harbor Commission, being part of the scheme for developing the harbor front.

At the present time one hull is being plated and keels laid for two other huls. The company expects to deliver three ships this season including one, the "Troja," which left in June for Montreal in ballast. Over the shipbuilding berths are the electrically operated gantries having a span of 68 feet. Both these gantries are complete except for the motors which have not been installed yet. There are five berths altogether, so the company will be able to build that number of ships at a time when the plant is finished. The Dominion Shipbuilding Co. will have a plant up-to-date in every feature and a valuable acquisition to the shipbuilding industry in Canada. Construction work on the plant was started in December, 1917, and considering the severe weather in the winter and difficulty of obtaining steel excellent progress has been made with the work.



VIEWS TAKEN AT THE PLANT OF THE DOMINION SHIPBUILDING CO.

The Types and Industrial Uses of Pyrometers

The necessity for accurate temperature control of industrial processes has led to the development of the various types of pyrometers in present day use, from the delicate laboratory appliance to that of an industrial manufacturing appliance. The following article reproduced through the courtesy of Alfred Herbert, Ltd., illustrates some of the types and their uses.

THERE is no need, at the present time, to insist upon the necessity for pyrometers in connection with heating processes, because that necessity is well recognized.

Contrasting the position to-day with that which existed say fifteen years ago, we find that the pyrometer has advanced from the limited position of a delicate laboratory instrument to that of an industrial manufacturing appliance. When the pyrometer was only to be used in the laboratory, in the hands of specially trained experts, the problem, from the point of view of the instrument maker, was relatively simple, although the instrument maker did not so consider it in those days. The laboratory pyrometer made occasional excursions into the works, usually with disastrous results, at any rate, to the pyrometer.

However, it became obvious that the information, with regard to the influence of accurate temperature regulation upon the resulting product could not be of any industrial value unless pyrometers could be applied to the industrial heating processes involved, therefore it was necessary to design pyrometers which could be used safely in the works.

The time has now come when the user of pyrometers under industrial conditions should know more about the principles upon which those instruments operate, the various factors which enter into the design and successful application of any type of pyrometer to industrial heating processes.

Pyrometer Classification

Pyrometers may be divided into two broad classes as follows:

"A." "Contact" or inserted pyrometers, in which some portion of the apparatus is actually subjected to the temperature to be measured such as:

1. Expansion instruments, the mercury-in-glass thermometer, and various other types in which differential expansion of some kind, either liquid or solid, is the means of measurement.

2.—The electric resistance thermometer, depending for its action upon the change in resistance by a coil of wire when its temperature changes.

3.—The thermo-electric or thermocouple pyrometer, depending for its action upon the electro-motive force or voltage developed at the junction between two dissimilar metals or alloys when that junction is heated to a temperature different from the remainder of the electric circuit.

4.—Melting-point pyrometers, in which the melting of some alloy or mixture of salts or clay indicates the passage above a certain fixed temperature, these may be termed "fixed point pyrometers."

"B." "Distant" pyrometers, in which no part of the instrument is subjected to the actual temperature to be measured, but which operates entirely at a distance from the hot body under measurement, comprising:—

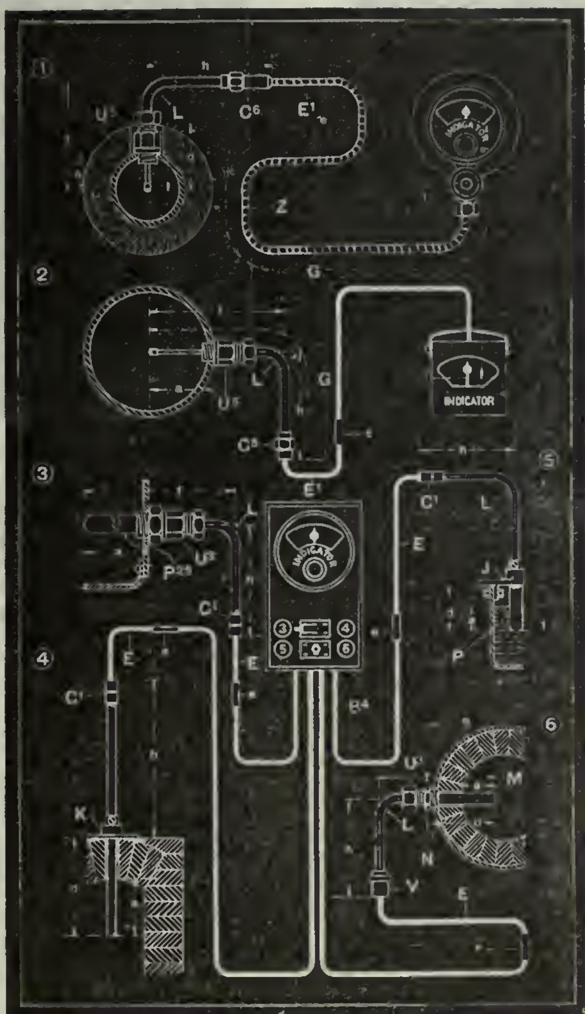


FIG. I.

5.—The optical pyrometer, in which the measurement of temperature is made by matching the brightness or color of the hot body against that of a standard in the instrument and computing the temperature by the adjustment which has to be made in the instrument.

6.—The "total radiation" pyrometer, which measures the temperature of the hot body by means of the radiated energy therefrom, both luminous and non-luminous.

Variation In Indications

It must be remembered that a pyrometer in which the sensitive portion is subjected to the temperature measures actually the temperature of its sensitive portion. It is clear that the temperature of the "hot junction" may be different from the material in the furnace, bath or other apparatus, due to the conditions briefly mentioned below.

(a) Thermal conduction of the pyrometer sheath. It is usual, and generally necessary, to employ an outer sheath to protect the actual thermo-couple from the action of the furnace gases or the material in a bath. Heat is transmitted from the furnace gases or bath through the sheath to the thermo couple "hot junction," and if this sheath is of large cross section some of this heat will be conducted away along the length of the sheath and will not reach the thermo-couple. This lost heat may result in the thermo-couple junction being at a lower temperature than the furnace or bath if sufficient depth of insertion is not provided.

(b) Temperature inequality in the furnace or bath. In direct fired furnaces, particularly when the door or other opening is large in relation to the furnace and is opened frequently, large differences may exist between different parts of the furnace.

(c) Unless the material which is under treatment is left in the furnace or bath a sufficient time it will not attain the temperature of the furnace, and therefore may be at a much lower temperature than that measured by the inserted pprometer.

These conditions and limitations apply with equal force to other types of pyrometer than the thermo-couple—in fact, in the case of the electric resistance or expansion instruments the larger bulk of the sensitive portion may aggravate the resulting errors.

Suitability of Contact Pyrometers

From the foregoing considerations it will be clear that the "contact" or inserted pyrometer is suitable for those cases in which the material under treatment remains in a closed furnace or in a bath for a time sufficient to ensure reasonable equality of temperature, and to cases in

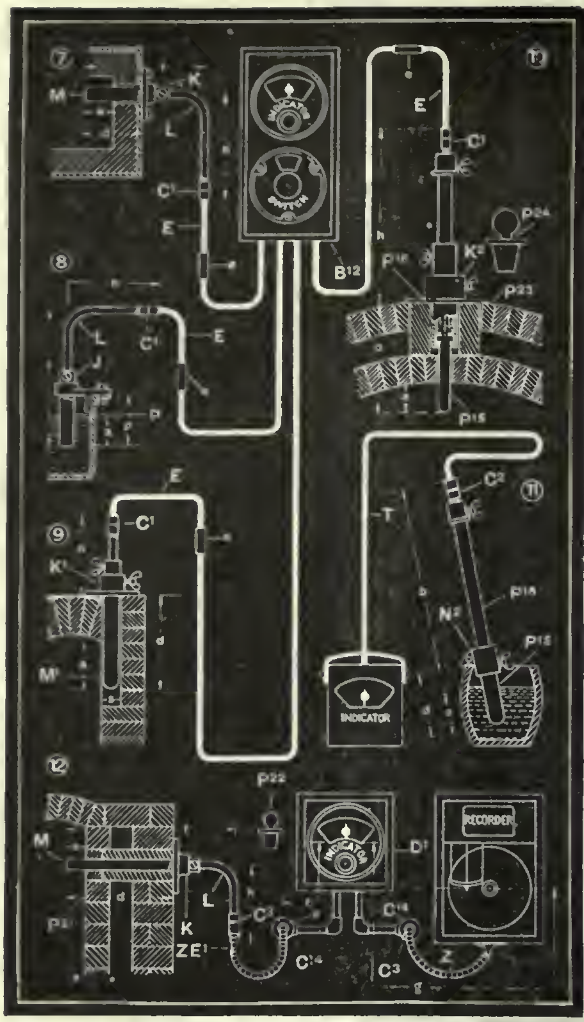

FIG. 2.

FIG. 3.

which the furnace temperature, as measured by the pyrometer, is kept at a steady figure and the material, of uniform heat capacity, is fed into and out of the furnace at a uniform rate.

Distant Pyrometers

Turning to the "distant" pyrometers, optical or total radiation, the measurement being made by the radiated light or heat, the pyrometer, if correctly used, will measure the temperature of the surface presented to it. That surface may be the inner wall of a furnace or the material in a furnace. The use of a radiation or optical pyrometer is subject to the following limitations:

(d) Unless the pyrometer is specially calibrated for other conditions, the hot body under measurement must be within a deep enclosure which is fairly uniformly heated. If these conditions do not obtain the measurement will be dependent upon the reflecting power of the surface of the hot body. It is, however, possible to calibrate these pyrometers for given surfaces out in the open or to apply a factor to the observed reading.

(e) The heat or light radiated from the hot body to the pyrometer must not be intercepted by smoke or gases containing solid particles. In the case of the optical instrument luminous flames, even though not containing solid particles, may, nevertheless, affect the reading very largely. The "total radiation" instrument is very little affected by clear flames, hence this latter type is frequently preferable for use by relatively unskilled observers.

The remarks under (d) and (e) show that the "distant" pyrometer is particularly suitable for work of an exploring nature and for the measurement of temperature of individual pieces of material or particular parts of a furnace. It is also, of course, preferable where the temperatures to be measured are very high and where consequently the life of the thermo-couple sheath and sensitive tip would be short.

The "total radiation" instrument has the advantage of being practically automatic in action, so that it can be used as a simple indicating or as a recording instrument, it does not require manipulation or adjustment by the user. It has the disadvantage of requiring a relatively large hot body surface for measurement, though this disadvantage is more apparent in the laboratory than in works practice.

The optical pyrometer can not be made directly indicating or recording, it depends upon the adjustment by the user to make a measurement. It is, however, useful when the hot body under measurement is small.

Turning again to the thermo-couple pyrometer, experience shows that the detail arrangement and application of the instrument to the furnace or bath have a very large influence upon its success.

Pyrometer Location

If the pyrometer is inserted through the crown of the furnace, as shown at Station 4 in Fig. 1, and projects deeply into the furnace space, it is frequently found to be in the way of the work in the furnace. If the same position is retained and the depth in the furnace reduced, one or two troubles may be met. If the furnace is uniformly heated the pyrometer may read low due to insufficient depth of insertion. If, alternatively, the furnace is heated largely by radiation from the furnace crown and flames at a higher temperature are passing along under the furnace crown to maintain its temperature, then the pyrometer will have its hot junction directly in the path of these flames, and will tend to measure their temperature rather than that of the material in the furnace. Added to this trouble is the fact that the life of the pyrometer sheath would be short under these circumstances.

Occasionally insertion through the side of the furnace is preferable in the manner shown at Station 7, Fig. 2, though the same class of difficulty may arise here. A preferable method of insertion is shown at Station 9, in Fig. 2. In this arrangement a pocket or channel is cut in the side of the furnace and the pyrometer sheath installed therein. In this way the flames in the furnace will not impinge directly upon the sheath, the sheath being heated largely by radiation from the furnace walls and from the material in the furnace.

In a large number of furnaces the arrangement is such that the pyrometer sheath has to cross an outer fire or flue space before reaching the working space of the furnace, and here again special consideration must be given to the details of installation. The gases in this fire space may be at a temperature very different from that in the working space of the furnace, and this temperature will influence the reading of the pyrometer unless particular care is taken to keep that temperature away from the sensitive tip of the pyrometer. Two different methods of installation are shown at Stations 10 and 12, in Fig. 2, to meet such cases.

When considering the application of the pyrometer to a bath of molten salt or metal, the sheath is extremely important, but it is not at all easy to secure a satisfactory sheath where the temperature is high. The bath, however, has the great advantage of giving good heat conduction from the bath to the sheath and approximate equality of temperature in various parts of the bath. Typical methods of installation are shown at Station 5, Fig. 1, and Station 8, Fig. 2.

In the foundry work on low melting alloys, non-ferrous alloys and aluminium constitutes a field in which the use of the thermo-couple pyrometer is being rapidly extended. Previous to the adoption of the Hoskins' alloys nickel-nickel chromium, there was no practicable thermo-couple which could be inserted unprotected by a sheath in these metals, the alloying effect was so great that the thermo-couple was destroyed after a very few readings.

The use of a sheath, as indicated at Station 11, in Fig. 2, is legitimate only where the time lag due to the heat capacity of the sheath is not an objection. Usually in foundry work the time lag of the sheath is an objection, and fortunately in such cases the Hoskins' alloy thermo-couple provides a solution of the problem.

It is made with fairly thick wires, and the tip of the thermo-couple is inserted directly into the molten metal, but removed as soon as a steady reading is attained. The thermo-couple wires are alloyed away by the molten metal at a rate varying with the nature of the alloy being melted, but with non-ferrous alloys and aluminium this rate is sufficiently slow to enable a large number of readings to be made before a thermo-couple renewal is necessary. When that renewal is necessary its cost is not very large, therefore the method is commercially justifiable.

After the fused junction between the two alloys has been destroyed by the molten metal the metal itself forms a junction so that this use of the pyrometer can be continued without making a new junction.

Details of Electric Circuits

Time and money spent upon the details of the electric circuit of a thermo-couple pyrometer are a good investment. It is a mistake to wire up a pyrometer with "bell wire." It has been found that heavy cable well protected—as, for instance, by screwed conduit, as shown at Station 12, Fig. 2—is well worth the time and trouble taken in the first installation. Similarly switch connections should be large, simple and easily adjusted. It should be remembered that the voltages available in pyrometer circuits are extremely low, frequently only small fractions of a volt and that circuit accessories which are quite suitable for lighting or power circuits will not give reliable results in a pyrometer circuit, the voltage is not enough to break down a film of oxide or other surface corrosion.

The indicating or recording instruments to be used with the thermo-couple should be sufficiently robust to withstand the unavoidable rough usage frequently met with in industrial work. Delicate suspensions are quite out of place in the works. Notwithstanding the maximum robustness attainable, it is advisable to choose favorable positions for instruments which are permanently installed.

Radiation Pyrometers

In the case of the "total radiation" pyrometer protecting sheaths are not required, and therefore the application of these instruments is in many cases much simpler. In view of the valuable exploring service which can be obtained from a radiation pyrometer, that instrument is most frequently made in a portable form, though there are many cases also where it is permanently installed as a recording instrument.

When considering a hot body inside a furnace or other approximately uniformly heated enclosure, the temperature measured is that of the surface presented to the instrument. For instance, at Station 1, Fig. 3, the surface being measured is the back wall of the furnace.

At Station 2 the peep hole has been coned out to allow of measurement of the temperature of the hot bodies lying on the floor of the furnace. This figure also indicates a method whereby a number of hot bodies being treated together may be made to provide a large enough surface for the pyrometer, although individually the hot bodies are small.

In Station 3 the door is shown raised to measure the temperature of the hot body "c."

As previously mentioned, the radiation pyrometer requires a relatively large hot body, but where a single small hot body is under treatment it is possible to measure its temperature if it is allowed to rest upon the floor of the furnace or against the wall of a furnace and to heat up until, by the eye, it has the same brightness as the surface against which it rests. Station 4 in Fig. 3 illustrates this method of use.

In using a radiation pyrometer it is, of course, necessary to prevent flames from the furnace reaching the pyrometer; it is equally necessary to prevent furnace gases from entering the pyrometer receiving tube, although these gases may not be visible as flames. There is usually little chance of this happening, but where the danger does exist it may be guarded against by arranging a cross blast of air to blow away any flames or products of combustion which might otherwise enter the receiving tube of the pyrometer. Such an arrangement is shown at Station 4, Fig. 3.

In the foundry the radiation pyrometer is useful for exploring the temperature of a pot furnace. In order that the temperature as measured may be independent of the nature of the surface under measurement the lid of the furnace is only partially removed, as shown at Station 6, Fig. 3.

Station 7 shows a method whereby the radiation pyrometer is used upon an adjustable bracket for permanent work as, for instance, a recording instrument.

As mentioned previously, the radiation pyrometer may be used, by means of a special calibration, upon hot body surfaces which are out in the open and not in uniformly heated enclosures. In such cases the reflecting power of the hot body must be taken account of.

Any surface which has reflecting power will radiate less energy than a non-reflecting body; it is not what is known technically as a "black body," that is, it is not a body which would appear dead black if it were cool.

Fortunately the oxidised surfaces of iron, steel, copper, whether molten or solid, radiate with an efficiency which is approximately a uniform percentage below that of the "black body," therefore the radiation pyrometer may be calibrated for use under such circumstances with sufficient accuracy for industrial purposes.

For instance, the temperature of a forging under the hammer may be measured, without interrupting the process, in a manner indicated diagrammatically at Station 8, Fig. 3. Of course, in such cases, it is necessary to remove dross or any non-adherent scale before a measurement is made.

When Le Chatelier first developed his thermo-couple pyrometer he employed thermo-couple wires of pure platinum against platinum alloyed with 10 per cent. of rhodium. He chose these wires because they were of high melting point and were relatively unalterable.

It has subsequently been found, however, that these wires are influenced seriously by reducing gases and the metal vapors which may exist in those gases. The wires become crystallized and also suffer a fall in E.M.F., and therefore a change of calibration, frequently of large amount, before the wires fractured.

Owing to the high expense of platinum in these alloys the wires are necessarily very thin and therefore liable to rapid attack, while the user is tempted to continue their use as long as possible owing to the very high cost of replacement.

Having chosen the alloys, the problem was then to devise a galvanometer suitable for use as an indicating instrument. The alloys, being expensive, were used in the form of very thin wires, about a fiftieth of an inch diameter; they were therefore of high electrical resistance and subject to a large increase in resistance when heated up in the furnace. In order to mask the change in calibration which would follow this increase in resistance, an indicating instrument was used which had a very high internal resistance so that the change in resistance in the circuit was relatively small. Since the copper wire in the coil of this indicating instrument was itself subject to an increase in resistance when the instrument became hot, a further "ballast" resistance had to be added in the form of a wire whose resistance did not increase when heated up. The net result of this high internal resistance was an instrument having very weak moving forces, because the electro-motive force or voltage of the platinum-platinum rhodium thermo-couple was in itself very small.

The discovery that "base metals"—that is, cheaper alloys—could be used as reliable thermo-couple opened up a new field in pyrometry, and it has been found that for all except very high temperatures the base metal thermo-couple forms a reliable industrial pyrometer. The Hoskins' alloys, nickel-nickel-chromium or nickel chromium-nickel copper have the advantage that they are much cheaper than the platinum alloys, and therefore may be used in the form of thick wires, and the further advantage of a much larger electro-motive force. As the wires are thick they are of low resistance, and fortunately also they have very small increase in resistance when they are heated up in the furnace. Therefore the necessity of having an indicating instrument of high internal resistance is no longer usually prominent. If the whole circuit resistance is low the current flowing in the circuit will be proportionately larger, and the net result is that the moving forces in a low resistance "base metal" pyrometer using the Hoskins' alloys are of the order of fifty times as great as those of the high resistance platinum alloy pyrometer. The gain in robustness and suitability for industrial work will be obvious.

It has been pointed out already that a sheath is necessary to protect the thermo-couple, as far as possible, from the influence of contaminating vapors. In the case of the platinum alloy thermo-couple this sheath must be literally impervious to gases. Unfortunately, the only materials which can approach this condition of imperviousness are, in themselves, fragile—for instance, silica (quartz) or glazed porcelain. In industrial work it is the sheath which sets the practical limit to the temperature at which a platinum alloy thermo-couple may be used, and this maximum temperature is unfortunately many hundreds of degrees below the melting point of the thermo-couple wires, therefore the fact that the melting point is very high is really of no practical value.

Admittedly, the base metal alloys have much lower melting points, but since the question of the sheath sets the limit still lower than the melting point, this fact is of small practical interest under industrial circumstances. To formulate an approximate general rule it may be said that above 1,000° C. for continuous work or 1,300° C. for intermittent work, no thermo-couple could be used under industrial conditions usually obtaining. For this reason the preference for the radiation pyrometer becomes greater as the temperature increases.

Of course the adoption of the low resistance circuit is quite out of the question with a platinum alloy thermo-couple, but the low resistance circuit cannot be advanced as an entire disadvantage to the base metal thermo-couple because the conditions of mechanical robustness would usually make advisable a fairly heavy gauge of copper connecting wire, and in any case the cost of the copper connections is relatively a small fraction of the total installation cost. In the choice of a sheath for a base metal thermo-couple the field is very much wider; metal sheaths may be used with consequent increase in mechanical robustness and reduction in cost. The Hoskins' nickel chromium alloys cast in the form of a sheath give particularly good service under severe conditions up to about 950° C. Of course, such a sheath cannot be used with a platinum alloy thermo-couple because the metal vapors emanating from the sheath itself would contaminate the thermo-couple.

To be continued

THE IRON SITUATION IN JAPAN

On account of the iron and steel situation in the United States, where, because of successive orders placed by the government for military requirements, and the increasing private demands that have developed in that country the demand has greatly exceeded the supply, the manufacture and delivery of steel for exportation to Japan cannot be undertaken unless the government's orders are first completely filled. Because of these government restrictions, even the orders already contracted for, to say nothing of new orders, cannot be shipped abroad without the government's consent, so naturally delay is inevitable. The question of how long this situation may last cannot be easily fathomed. At any rate, for the present the import of American iron into Japan cannot be proceeded with satisfactorily.

In anticipation of higher quotations that may result, exporters and manufacturers in the United States are induced to make conditional contracts for Japanese orders consequent upon the difficulty in obtaining licenses to ship. On the other hand, Japanese merchants are holding over their orders fearing any future turn of events. This naturally results in the gradual decrease of imports, and it is impossible to know what change may occur in the market so long as imports of iron and steel cannot be carried on satisfactorily.

The price of iron has run up over 20 per cent. during the last month, while plate iron has also advanced, due to shortage of stocks. The ordinary inch goods rule at yen 45-46 per 100 kin, and the two-fifth inch goods in the neighborhood of yen 46-47 per 100 kin.

In the early part of May two-fifth inch goods were somewhere in the neighborhood of yen 1,100 per ton, but now the price of yen 1,200 is reached. Rod iron has had a sharp rise within the last few days, and at the same time the market for such has been very busy. Round iron, on account of its cheaper quotations, advanced also, the ordinary inch goods being quoted at yen 14, and the square goods at yen 15-19 per 100 kin. Nails and other minor goods have considerably stiffened, 3-5-inch to 1 1-5-inch goods bringing yen 32 per 100 kin.

Galvanized plate iron rules higher by yen 3-40 to yen 3-50, while galvanized wire has advanced about 5 per cent. All of these have advanced by 20 to 30 per cent. since last week. It is thought that another strong tone may prevail with the difficulty in importing American iron goods.

UTILIZATION OF WESTERN LIGNITE

A plan for the utilization of Western lignite that is likely to have far-reaching results has been formulated by the Council for Scientific and Industrial Research, of which Dr. A. B. Macallum is chairman.

The provinces of Manitoba and Saskatchewan import annually from Pennsylvania about a half million tons of anthracite for domestic fuel, and send out of the country, therefore, more than $4,000,000. There are in these provinces it is estimated, about fifty-seven million tons of lignite of a poor grade, and consequently, disqualified from serving as domestic fuel. It has been demonstrated, however, that they can be carbonized and briquetted, and that the product thus created is an equivalent of anthracite.

As a result of these investigations, conducted by the lignite committee, of which R. A. Ross, of Montreal, is the chairman, the council recommend that the government establish a plant in southern Saskatchewan to turn out 30,000 tons of this fuel yearly, the estimated cost of which would not probably exceed $7 per ton at the plant. The three governments concerned are about to sign the proposed agreement, the Dominion Government having already involved its share of the total cost of the plant. The governments expect to appoint the commission to operate the plant at an early date.

CONTINUOUS SHELL, HEAT TREATING FURNACE FOR 75 AND 155 M.M. WORK

A CONTINUOUS furnace for heat-treating 75 mm. and 155 mm. shells is being manufactured by the Strong, Carlisle & Hammond Co., Cleveland, Ohio. This furnace, which can be used for both hardening and drawing operations, is of the underfired type, constructed with a working tile floor 27 in. wide by 20 ft. long. In operation the flame from the gas or oil burners enters a combustion chamber beneath the working tile floor, and the products of combustion escape through ports in the arch. The furnace shown in the accompanying illustration is oil-fired from burners at the side and is being used for treating 75 mm. shells. In heat-treating 75 mm. shells, four rows of shells are passing through the oven at a time, and each row is supported by two 1½ in. steel bars. The nose of one shell pushes against the base of the shell just in front of it. At the charging end of the furnace is a table supporting the shells and also two cross-heads that move horizontally. Each cross-head pushes two rows of shells through the oven. The cross-heads are moved back and forth by means of two cranks that are rotated by means of a worm gear and worm. The balance of the drive consists of a pinion, gear and two cone pulleys. The cone pulleys are used so that the speed can be slightly varied. In heat-treating larger shells up to 155 mm. the charging end of the furnace is equippel with a hydraulic ram in place of the crank arrangement described above. The manufacturers can supply a master clock and bells so that the bells will ring at certain intervals and notify the operator that the hydraulic ram is to be operated. When fitted with this arrangement the furnaces for the larger shells are not automatic like the furnace for heating the 75 mm. shells.

The furnaces are shipped from the factory completely set up and crated. Upon arrival at the customer's plant it is only necessary to remove the skids and make one air and one oil connection for the burners.

The hood over the charging end as shown in the illustration was installed to carry away the heat which helps to keep the room cool. The pullies and belt shown at the left hand of the illustration drive the crank feeding arrangement. The quenching tank is shown at the far end of the furnace.

CONTINUOUS FURNACE FOR HEAT TREATING 75-MM. SHELLS.

BECOMING AN ENGINEER

By Batiste Lefore

My name is Batiste Lefore, I am ze french mans, I have been having ze troubles wis ze steam plant las week.

I was ze sweep de floor man in ze factory but every time de engineer clean out dose boilers he ask for Batistee to help hem. Well dat engineer he go to fight de hun and me Batistee being old fellow, I stay home. De boss say Batistee, how you like to be engineer and mak tree dollar a day. I say, sure for dat is fine job, all dere is to do is shovel in coal to keep dat steam up, oil up de engine and shafting, lace de belts, sharpen de knives, wash de windows, and sit down when nobody can find anyting for me to do. Sure, I make a grab for such a snap and de next morning I am on de job at 5 a.m. I fill up the fire hole wid coal and at 7 a.m. de whistle I blow for start work, de big valve called safety she be blowing at de same time.

After awhile de Boss come in and say, damn it Batistee why you let dat safety valve below. I say I tink she do dat for safety. He look at de glass and say where is de water, I tell him it is in de boiler I nevaire take eet out. He yelled pull out your fire or she will blow up, den he runs away and I runs after him. Well pretty soon de fire goes out and we get the boiler men to fix her up again and de boss show me how to put in de water and say do not let the safety valve plow so much. I am getting on fine and one day when I am painting de walls a feller comes in and says are you de engineer, I tell him I am him. He say I am inspector Dan Sharpise. Where is your certificate? I say, what is dat. He say a licence. I tell him I am not a dog and do not need a tag. He say you go to dose examiners and get a licence or I put you in ze coop. I say sacre, I not go in any hen coop. I go to see dese examiner fellow. He say Batiste vos you an engineer? I say sure. He say describe de engine you run. I tell him dere is a pipe to take de steam in and anoder one to take it out and a rod runs out and in and turns de wheels around. McGee he say. Ha name de valve on de engine. I tell him de only valve on de engine is de one de Boss called de trottle. He say, hang it man, I mean de valve in de steam chest. I tink dat McGee he been having some 2½ per cent. to talk about chests on de engine.

He ask me do I know how much lead and lap de valve him got. I start to laugh for I tink he joke me. I say sure McGee. I tie de string to dot valve and lead him around de mill and let him lap up some milk like a cat. Den McGee be get red in de face and say damn some times more. Den McGee ask me if it is good plan to put valve between boiler and safety valve, and I say, sure, because if I had valve dere I could shut him when de steam gets high pressure. He say damn again. He say to me I expect if de water got out of de glass and a big fire on you would run away. I say, sure, again, dat is just what I did do a little while ago. He say, see here Batistee, you no damn good as an engineer, go away and learn sometings and come back next year. Anyhow I am going to write to dose correspondence schools on Yongs street, Toronto, and pretty soon I will be a mail order engineer wid a salary of $3 a day, and noding for Sunday or overtime work. By gar, dere is a lot to learn in dat engineering.

The best blowoff valve arrangement is to place a quick-opening straight-way valve next to the boiler with an asbestos-packed iron body plug cock of the angle type at the elbow connecting the straight blowoff pipe with the main blowoff line connection.

The hottest part of the boiler furnace is just behind the bridgewall and frequently it will be found that more scale is thrown here than at any other point.

Principles & Practice of Mechanical Sketching & Drawing-IV

Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simpler Types—A Practical Course Prepared Especially For Younger Men and Newcomers in the Industry

By Terrell Croft

ORTHOGRAPHIC PROJECTIONS

MAKE your drawing tell the whole story. Remember that mechanical drawing is a language, and that any working sketch which you may turn out is a graphic description of what is to be made or done. If the sketch is incomplete—if it lacks the requisite dimensions or views or details—the result is the same as when an author omits certain important words from his book. Be always certain that the ideas which you desire to convey are shown completely. Don't be selfish when you make a sketch, but consider that probably others besides yourself may have to work from or refer to it in the future. Details count for much in mechanical drawings.

If the thing is considered solely from the standpoint of economics it can be demonstrated readily that it is extremely wasteful to omit proper information from drawings. The pattern-maker, the machinist, the erector, and others down along the line may spend an aggregate of hours in ferreting out from a sheet facts which could have been incorporated in a few moments by the originator of the sketch.

Proportions and Perspective

Practically all working drawings are orthographic drawings, and the different "views" which comprise them are orthographic projections. While orthographic is rather a long and awkward word, it is used so frequently that it is essential the serious student of the language of lines (mechanical drawing) understands precisely what it means. It is the intention, therefore, to now examine the situation rather minutely. The underlying principle is very important because, as suggested above it is the basis of practically all engineering drawing. If a man once masters the principles which it is proposed to discuss, he will thereby be saved much future time and trouble—both in the making and in the reading of working drawings.

What the word "orthographic" means may be ascertained by referring to any standard dictionary. There it will be found that it is applied not only to drawing but to music and to grammar. In each case orthographic relates to the rendering of a thing in its true sense or true proportion. Thus, orthography in grammer relates to the correct spelling of words. Orthography in music has to do with the representation of tones and effects by the proper characters. An orthographic drawing is one which is in correct proportion.

There is a distinction between an orthographic and a perspective drawing. In an orthographic drawing (for example any ordinary working drawing) the lines are in their true proportions. In a perspective drawing the lines are not in their correct proportions although they appear to the eye to be so. If, in a perspective drawing the lines are in their correct proportions they will not appear to the eye to be correct.

For example, consider the perspective drawing (Fig. 1) of the steam chest cover. This appears to the eye to be in proportion and to be a fair representation of the object under consideration. However, since this is a perspective drawing it is really not in proportion. As shown in Fig. 2, which is a reduced reproduction of Fig. 1, the lines extending away from the realer intersect at a vanishing point P. It is apparent then that in Fig. 1 the line LG is shorter than the line EF, whereas in the actual object we know that these two lines representing edges would be of precisely the same length. Also in Fig. 1 GK is shorter than FJ, while in the actual cover they would be of exactly equal dimensions.

Orthographic Projection Necessary

From a consideration of the facts outlined just above it is evident that perspective drawings are not suitable for general engineering purposes for which it is usually desirable to represent edges,

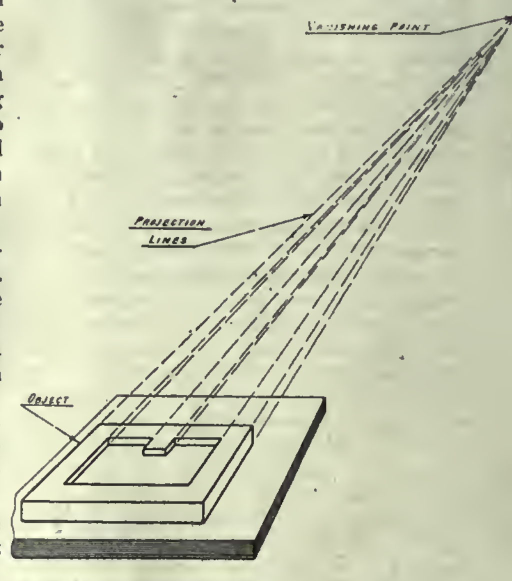

FIG. 2—SHOWING HOW THE LINES OF A PERSPECTIVE DRAWING MAY IF PROJECTED INTERSECT AT A DISTANT POINT.

surfaces, and corners in their true proportions. But with orthographic drawings this requirement of true proportion is satisfied, as will be described.

The function of a working drawing or working sketch is to show on one plane —the surface of the paper upon which the sketch is made—a picture of the object under consideration. The object which the drawing shows has three dimensions—length, breadth and thickness —while the plane upon which the drawing is made has only two dimensions, length and breadth. By utilizing the principles of orthographic projection it is, as will be shown, possible to plot on the apper plane a picture (usually comprising two or more views of the object in question) which will show it in true proportion and in all of its details.

An example illustrating how an object may be shown in orthographic drawing is given in Fig. 3. If the steam chest cover of Fig. 1 be observed with only one eye (E, Fig. 3) open, the observer, standing so that he is directly in front of the center of the object, will then see merely a rectangle (A^1 and B^1, Fig. 3). If now a sheet of glass, S_1, be inserted at right angles to the line of vision and on this glass a trace of the rectangular

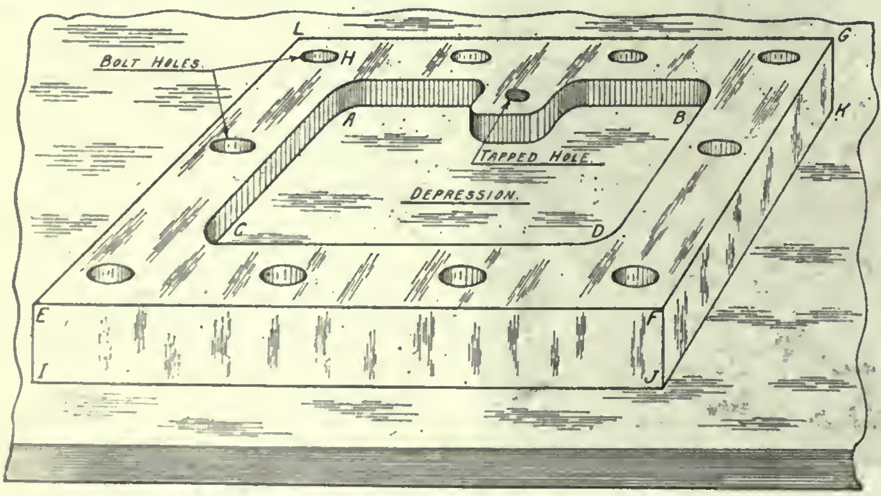

FIG. 1—PERSPECTIVE VIEW OF STEAM CHEST COVER

outline as it appears to the observer be made with, say a pencil of soap, this trace, AB, will also be a rectangle. This rectangle will, obviously, be an orthographic drawing of the front of the steam chest cover because it is a reproduction in correct proportion of the front of the cover. But it is apparent that this one front view of the cover does not give sufficient information to enable a manufacturer who has never seen the cover to reproduce it in his shop. This front view tells nothing as to the depth or the contour of the body of the casting. If, however, another glass sheet (S_2, Fig. 4) be arranged directly over the cover and at right angles to sheet S_1, then the top view of the object can be traced with the soap pencil on this glass pane. The front and top views thus obtained give considerable information relating to the construction of the cover but do not define it completely. To insure more adequate definition another end view (E_1 and E_2, Fig. 5) can be traced if the cover is arranged in a glass box on the end of which the end-view trace is drawn with the soap pencil.

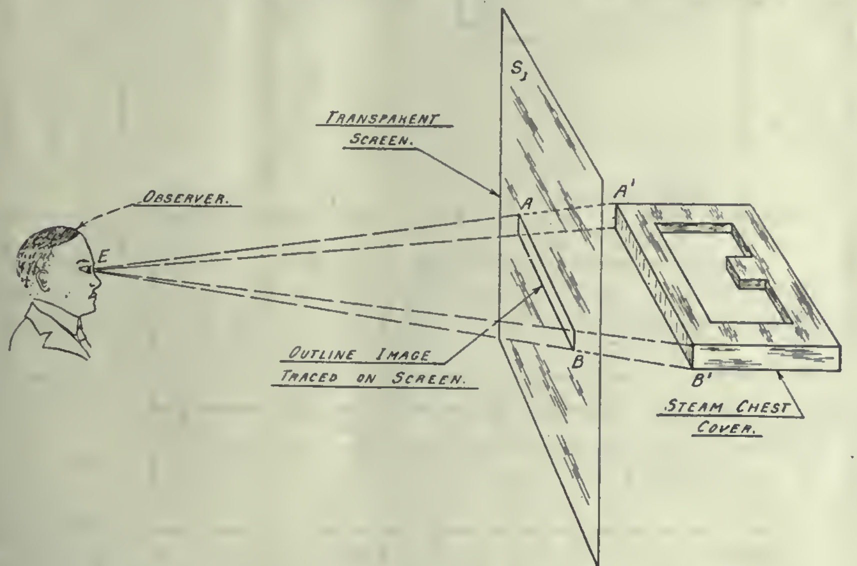

FIG. 3—ILLUSTRATING THE IDEA OF ORTHOGRAPHIC PROJECTION.

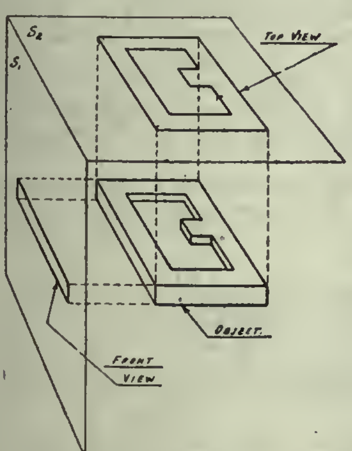

FIG. 4—TOP AND FRONT VIEWS OF STEAM CHEST COVER TRACED ON TWO GLASS SHEETS WHICH ARE ARRANGED AT RIGHT ANGLES TO ONE ANOTHER.

Complete Views

These three views traced on the faces of the glass box—the front view, the top view, and the end view—completely determine the over-all dimensions and the contour of the object. But, as drawn on the glass box in Fig. 5, each of the three lies in a different plane. If the information which these views convey is to be transferred to a sheet of drawing paper, all three of the views must somehow or other be transferred to the same plane. How this may be done is delineated in Fig. 6. The glass sheets upon which the end view and the top view were traced have each been swung through an angle of 90° so that now they all lie in the same plane with the sheet upon which the front view was drawn. In Fig. 6 these three views have been shown shaded to insure that they will stand out clearly. In the actual drawings on the glass the views would, of course, appear in outline as shown in Figs. 4 and 5. If a piece of tracing cloth or paper be stretched over the glass plates of Fig. 6, we could then trace on this sheet the orthographic drawing of the chest cover, which would appear as shown in Fig. 7.

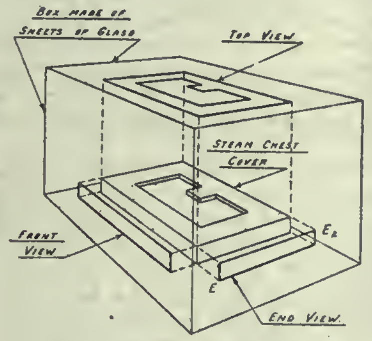

FIG. 5—THE STEAM CHEST COVER IN A GLASS BOX ON THE SIDES OF WHICH IMAGES HAVE BEEN TRACED.

Three different views are, as shown in Fig. 7, usually necessary to define adequately the proportions of an object. The front view is sometimes called the front elevation or vertical projection because it is a reproduction of the projection of the object on a vertical plane. The top view is also sometimes called the plan or the horizontal projection. The side view is sometimes called the side elevation or profile projection.

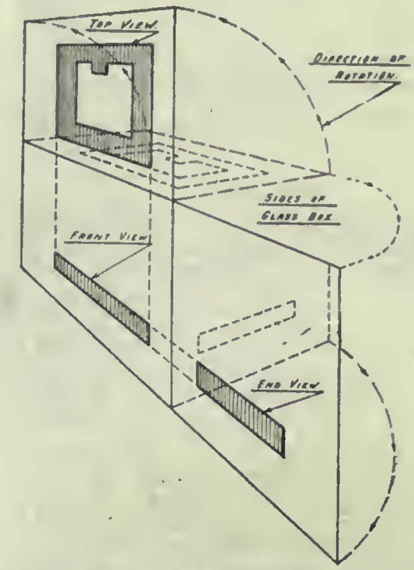

FIG. 6—HOW THE IMAGES TRACED ON THE SIDES OF THE GLASS BOX MAY BE ROTATED SO THAT THEY ALL LIE IN THE SAME PLANE.

How planes, edges, and corners are represented in orthographic drawings will for the most part, be evident from a consideration of what has preceded. Thus it is true that in an orthographic drawing, an edge is always represented by a line. If it is assumed that the line of vision of the observer is at right angles

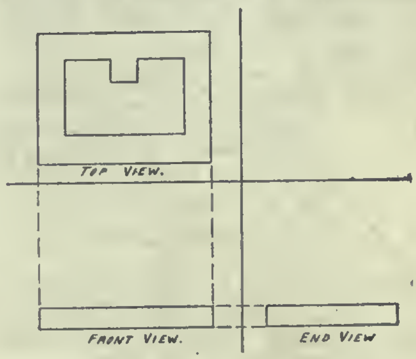

FIG. 7—ORTHOGRAPHIC DRAWING OF THE STEAM CHEST COVER TRACED FROM THE IMAGES OF THE GLASS PLANES OF FIG. 6.

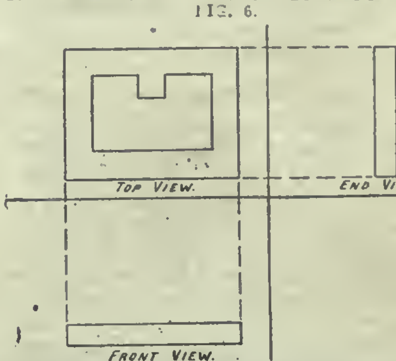

FIG. 8—ORTHOGRAPHIC DRAWING OF THE STEAM CHEST COVER REARRANGED SO AS TO CONFORM TO STANDARD USAGE.

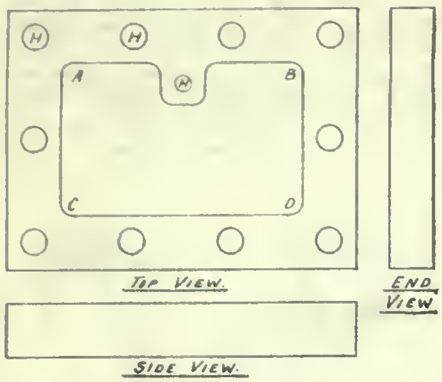

FIG. 9—ORTHOGRAPHIC DRAWING WITH THE DIFFERENT VIEWS BROUGHT TOGETHER BUT WITHOUT DOTTED LINES TO INDICATE HIDDEN SURFACES AND INTERSECTIONS.

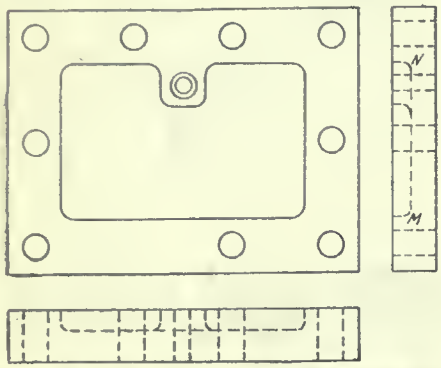

FIG. 10—PARTIALLY COMPLETED ORTHOGRAPHIC WORKING DRAWING OF THE STEAM CHEST COVER

to the line, then the line will be shown in its true length. A straight edge or surface viewed at its end appears on the drawing as a point. A corner of the object always appears on the drawing as a point regardless of the direction from which it is viewed.

Invisible or hidden surfaces or edges are, when observed side on, represented

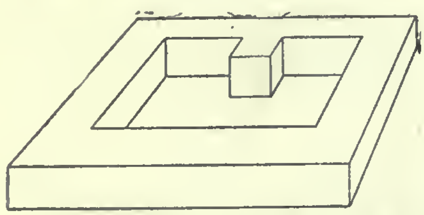

FIG. 11—HOLLOW BLOCK WITH INTERNALLY PROJECTING LUG.

in the orthographic drawing by dotted lines. No dotted lines are shown in Fig. 7. How they should be introduced will be treated later.

Arrangement of Views

In arranging the views in an orthographic drawing it is usually customary to place the top view in the upper left-hand corner of the sheet, front view below it, and the end view at its right, as shown in Fig. 8. This is ordinarily the preferable practice as it allows space in the lower right-hand corner of the sheet for the title. However, there is no reason why one of the other possible arrangement should not be followed, provided the ideas of orthographic projection are used consistently. Thus,

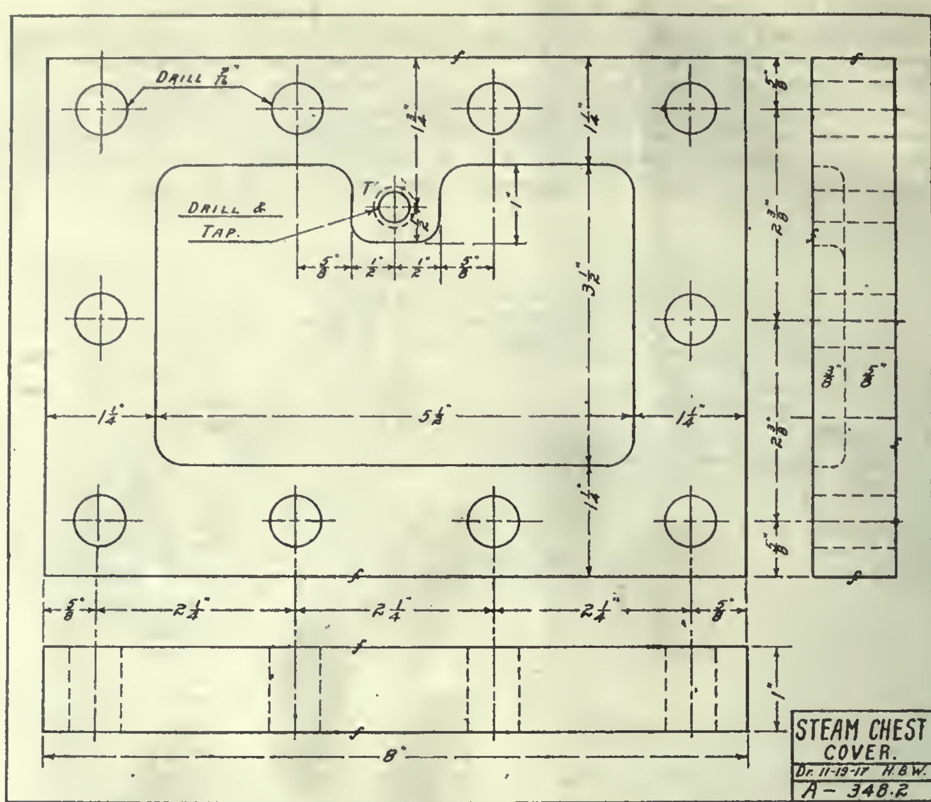

FIG. 12—THE COMPLETED WORKING DRAWING OF THE STEAM CHEST COVER.

Fig. 7 shows a perfect reproduction of the steam chest cover. It may at times be desirable to show above its plan view a rear view of the object and in addition a right-end view and a left-end view. Or it may serve more satisfactorily to show a left-end view without a right-end view.

To complete the orthographic drawing of the steam chest cover shown in Fig. 8 into a finished product, the first step would be to move the views closer together, which would result in the plot detailed in Fig. 9. Also the bolt holes, H, which have been omitted from Figs. 2 to 8, inclusive, to insure simplicity, should be included. Next, the dotted lines representing invisible surfaces should be incorporated. The resulting sheet will then appear as in Fig. 10. The importance of the dotted lines is apparent when one considers that unless these are shown one would not be able to learn from the drawing (Fig. 9) whether the depression ABCD extended entirely through the block as shown in Fig. 11 or only partially through, as shown in Fig. 1 and specified by the dotted line MN in Fig. 10. Finally to complete the drawing (Fig. 12) add the center lines, dimensions, dimension lines, arrow heads and title. Note (Fig. 12) how screw threads for the tapped hole T are indicated.

Number of Views Required

The number of views necessary to definitely describe the object in the picture language of orthographic drawing is a thing which must be determined for each case on its merits. For example, occasionally, as illustrated in the anchor-bolt example of Fig. 13, one view with appended notes transmits all of the data that is necessary. It is seldom, however, that one view of an object defines it sufficiently. If one considers that the general contour of the top views of the objects of Figs. 1, 11 and 16 would be precisely the same, the importance of this feature is apparent. A side or a front view would be necessary to show the difference in contours of the objects of Figs. 1 and 16. How the construction of Fig. 11 is shown by dotted lines to be different from that of Fig. 1 has been explained in connection with the discussion of Fig. 12. Certain objects, such as the cylindrical spacer of Fig. 14, can be shown, so that there is no possibility of misunderstanding their contour, with two views.

Another example of a two-view drawing is that diagrammed in Fig. 15, which shows the perspective view and the orthographic projections of a cast iron channel washer or plate which may be used for clamping shaft hangers or similar devices to a twin-channel girder

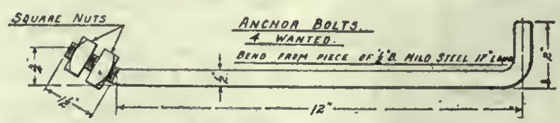

FIG. 13—AN ANCHOR BOLT. EXAMPLE OF AN ISOMETRIC DRAWING IN WHICH ONE VIEW TELLS THE WHOLE STORY.

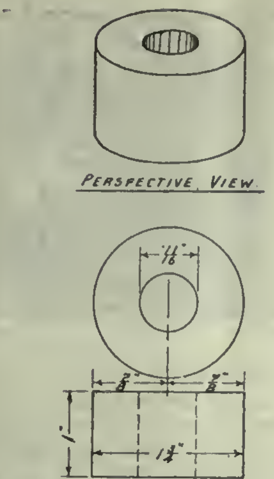

FIG. 14—PLAN, ELEVATION AND PERSPECTIVE VIEW OF CYLINDRICAL SPACER.

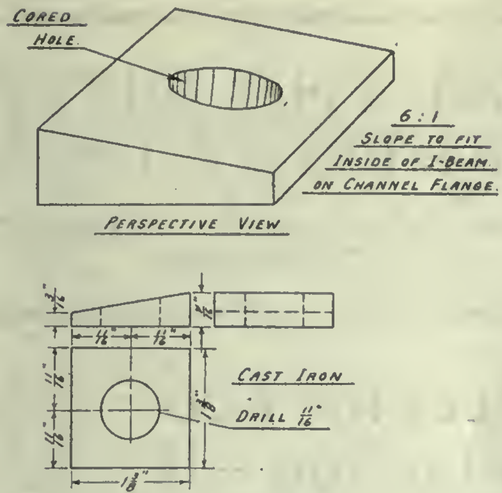

FIG. 17—CHANNEL OR "I" BEAM FLANGE WASHER.

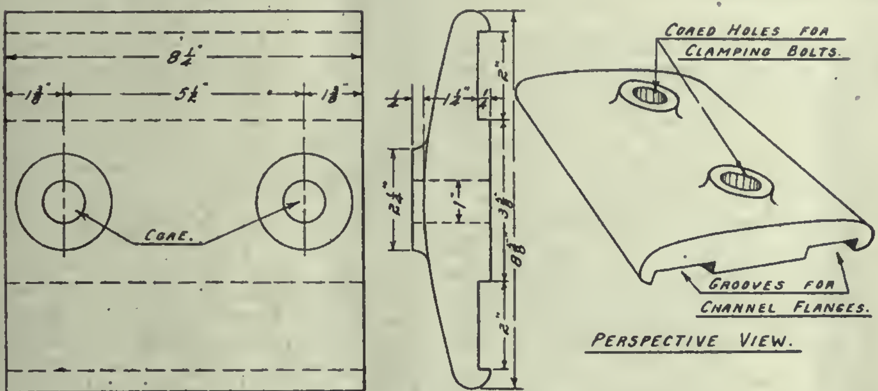

FIG. 15—DETAILS OF CHANNEL PLATE, CAST IRON.

or roof truss. An object necessitating three views for its perfect definition is the flange washer described in Fig. 17.

Isometric Example

An example of a three-view isometric drawing is given in Fig. 18 which shows the proportions of a casting which has been utilized very effectively in certain industrial shops and plants for supporting overhead motors and shaft hangers. These beams, for such they are, are clamped between two twin-channel girders which are erected for their reception. The construction thus provided is fireproof and very substantial.

Sometimes sections are used in combination with orthographic views to indicate the construction of an object. Fig. 19, which shows a cable or pipe-rack casting which is designed to hook over a bolt inserted through a web of a steel tee, constitutes a good illustration of this practice. The general subject of sectional reproduction and section lines will be treated in a future article.

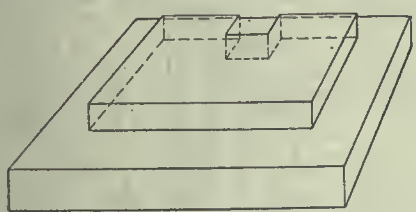

FIG. 16—RECTANGULAR BLOCK WITH EXTENSION PROJECTING FROM UPPER FACE.

LIQUID FUEL APPLICATIONS

According to one of the large oil companies, liquid fuel is to be found giving highly efficient service in bakeries, breweries, brass and other foundries, bedstead factories, bolt and nut works, boiler shops, cement works, cycle works, chemical works, dyers' works, drop-forging works, dynamite works, distilleries, engine works, elecricity generating stations, glass works, pottery works, railway works, steel rolling mills, sugar refineries, shipyards, tube works, tool works, tramway undertakings, waterworks, wagon works, and wire works. Amongst more or less unfamiliar processes in which it is used are tempering magnets, drying tea, smelting tin and ore, shrinking tires, soldering, heating rivets, distilling petroleum, bending plates, heating buildings, galvanizing, dust destruction, carbonizing lamp filaments, and singeing cloth. It is also used in many metallurgical processes in addition to those mentioned.

To face a cast-iron pulley with leather apply acetic acid to the face of the pulley with a brush, which will roughen it by rusting, and then when dry apply a cement made of one pound of fish glue and one half pound of common glue, melted in a mixture of alcohol and water. The leather should then be placed on the pulley and dried under pressure.

The fire point of an oil is the lowest temperature at which the oil itself ignites from its vapors when a small test flame is quickly approached near its surface and quickly removed. Since the fire point is always above the flash point the fire point value becomes of minor importance for this paper.

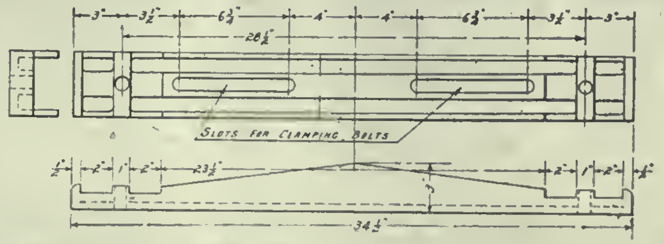

FIG. 18—CAST IRON MOTOR OR SHAFT HANGER SUPPORT TO SPAN ACROSS TWO CHANNEL GIRDER (THIS IS AN EXAMPLE OF AN ISOMETRIC DAAWING FOR WHICH THREE VIEWS ARE NECESSARY.

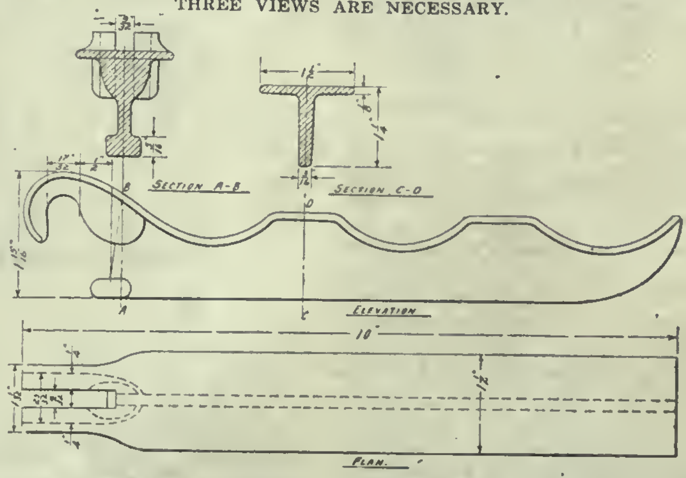

FIG. 19—CABLE OR PIPE RACK DETAILS. THIS SHOWS HOW SECTIONAL VIEWS MAY BE USED IN COMBINATION WITH ORTHOPEDIC PROJECTIONS TO CONVEY THE REQUIRED INFORMATION.

Efficient Appliances for Economic Shell Production—II

By J. H. RODGERS
Associate Editor Canadian Machinery

Radius Grinding Cutter.

While the production of the 18 pdr. has been discontinued here in Canada many devices were developed for the rapid and economic manufacture of this size of high explosive shell. A very interesting and serviceable device for the grinding of the boring cutters is illustrated in Fig. 9, and as this attachment could be easily applied to almost any make of small grinding machine, the same principle might very well be adapted to many other lines of similar work. The appliance consists of a base A that can be secured to the table of the machine. The upper portion of this base is fitted with a slide in which is placed the rest B, the top surface of which is inclined at an angle of about 6 degrees for grinding the clearance on the cutters that are held in a specially designed block E, which is provided with pivot hole so located as to revolve on the pin G to form the radius on either side of the cutter, the block being reversed to perform the operation on the opposite side. The cutters are held in position by means of the screw F.

Stops H and I are provided at the desired positions to regulate the travel of the block from one position to another, and also act as a guide when grinding the straight portion on the face or the side. Close adjustment is obtained by the screw J and locking nut K.

Unique Grinder For Shell Bore

It is seldom that the bore of the shells is sufficiently smooth after the finish tooling has been performed, and for this reason, and likewise to conform to the specifications it is necessary that some method be adopted to put a finish on the bore that will meet the requirement of the contract and pass the examination of the inspectors. The method generally adopted for this purpose has been to grind out the irregularities by some simple device constructed for the work. Many different appliances have been developed for smoothing the surface and nearly all of them have particular advantages that have kept them in continual service. As has been the case in all other impromptu appliances the available material about a plant has been the chief reason for the wide variance in the design of this and similar wheel E, a thrust ring F being fitted to the forward end of the shaft I which is supported in the long babbited tubing K, the latter being securely held in the casting L. A dust cap M is located on the forward end of the chuck. The grinding wheel H is fitted to the end of the shaft I which is supported in the equipment.

The device shown in Fig. 10 may appear quite complicated but it has proved very efficient and is of special interest owing to its unique construction and its method of operation. The supporting frame is made from two S shaped structural members held in position by the channel irons shown. Two solid steady rests are secured on one end that carry the large collet chuck D that is operated by means of the hand long babbited tubing K, the latter being securely held in the casting L. A dust cap M is located on the forward end of the tube to prevent the dust from destroying the bearing. A piece of cold rolled shafting is secured in the middle of this casting L, which acts as a plunger in the cylinders T T, one of these being located at either end of the machine and supported in suitable brackets—not shown. The adjustment of the cutting wheel is obtained by means of the nut Q that is fitted to a rod P connected to the bracket at the point O. The fixture is so arranged on the shaft R that by a simple movement the support together with the grinding shaft, can be swung aside to remove the shell from the chuck. The longitudinal feed for the grinding wheel is obtained by a combination of compressed air and oil, the latter being contained in a couple of spoiled 8 inch shells and so connected that the air supply coming through the pipe 2 is supplied at will to either cylinder by the control of the three-way

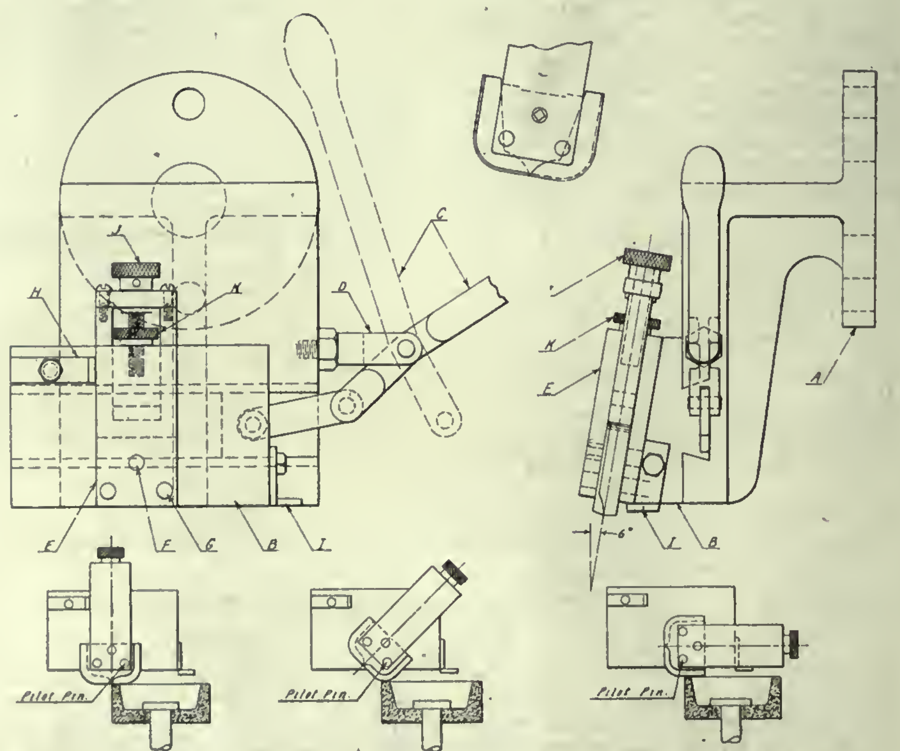

FIG. 9 RADIUS GRINDING FIXTURE 18 PDR. H.E. SHELLS.

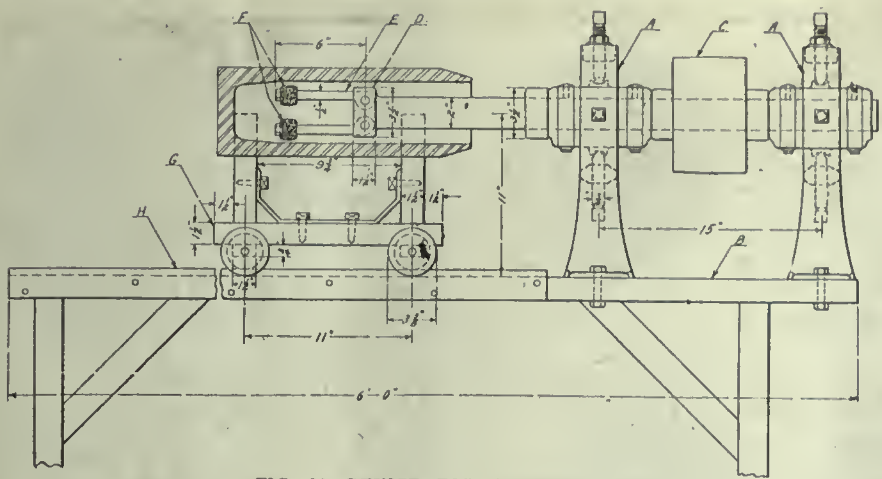

FIG. 10—DEVICE FOR GRINDING BORE.

cocks 4, 4, these being so connected that they operate in unison. As the air passes through the pipes 5 and into the upper portion of the shell reservoir, the oil is forced up the pipes U and against the cold rolled shaft plunger. The speed of the movement can be regulated by adjusting the valve V whereby the flow can be adjusted to suit the desired conditions. This appliance while rather cumbersome has nevertheless given very good results.

Another Method For Grinding Bore

A somewhat simpler device designed for the same purpose is shown in Fig. 11. In this particular case the bearings for the grinding shaft is composed of two 11-inch hangers fitted to a suitable plank B, the shaft being operated by the pulley C. On the grinding end of the shaft is the piece D in which is supported the two arms E that carry the grinding wheels F; these are circular in shape and held in position by the small nuts shown. To renew the cutting properties of the wheels it is simply necessary to slacken the nuts and give wheels a slight turn. The carriage is composed of a wooden framework mounted on two small trucks that run in a parallel direction to the grinding spindle on the track H. It is very advisable that the axis of the shell when resting on the carriage should be central with the inner shaft, as any eccentricity would tend to destroy the regular operation of the fixture.

Three-Piece Boring Cutter

Boring bars are numerous in design but the general principal is invariably the same. In the one here shown in Fig. 12 the cutter is made in three distinct pieces, the portion used to form the base of the shell and the profile being located in the end of the bar, while the parallel section of the bore is derived by the two side cutters. The reason for this design was the saving that was effected in the use of high speed steel, as smaller bars could be used in making the cutters. The side cutters can be adjusted by means of the two small headless screws E. The cutting lubricant is distributed to the side by two inclined holes leading off from the central hole.

Three-Bladed Cutter Head

A three-bladed cutter that has given excellent satisfaction is illustrated in Fig. 13. The cutter head A, which is made of machine steel or cold rolled, is fitted by means of a screw and taper, to the machine steel bar B which is held in position in the turret or back rest of the machine. Three equidistant slots are milled out in the head A to receive the three cutters C C and D, the last one having an extension on the forward end for facing purposes, a suitable slot being milled across the face for support to this cutter. These cutters are secured in position by means of wedge blocks E and fillister screws F. The use of the three cutter method has a stiffening tendency and assists in steadying the cutter when in operation.

Finishing Inside Profile.

Following the nosing operation of the shells and for the same reason explained in a previous section of this article, it is necessary that any "irregularities in the interior, resulting from the bottling operation, should be removed before the shell can be accepted by the inspectors. Owing to the confined space that is now left for machining of any kind it becomes a difficult proposition to accomplish this purpose, particularly if the irregularities on the inner profile are very pronounced. The small opening left in the nose of the shell prevents the use of a boring bar that will be stiff enough to do any serious amount of machining, so that the bars that have been developed for this purpose are generally of a character that great care requires to be exercised in their operation. The one shown in Fig. 14 is similar to that used in a large number of plants, this being comprised of a solid bar so shaped as to give the maximum rigidity under the conditions present. In order to obtain the maximum holding power for the screws they are placed near the center of the bar, and for this reason the back edge of the cutter is provided with three slots through which the screws pass. The outer end of the bent bar is turned to receive the small roller shown that serves as a guide for the finishing position of the cutter, preventing the same from cutting below the point intended. Lubricant is forced to the cutter through the center of the bar and out through the inclined opening. In using these cutters it is necessary that the shank be removed from the support before the bar can be removed from the shell.

Special Inside Profiling Device.

A very interesting profiling device was developed by the engineers of a large plant for cleaning out the shell after the nose has been closed. The main body A of the fixture is made from a steel forging, the shank turned to fit the hole of a turret and additionally supported by means of the keyway B. The cutting tool C is contained in the slot cut in the center of the bar extension and is pivoted by the stud D, the outer end of the cutter swinging through a small arc and being a working fit at the point E. The device is operated by the handle F which is secured to the sleeve G threaded in the boss on the main holder. Through the center of the sleeve is fitted the bolt I, the ball head of which bears against the tail of the cutter. This tail is maintained against the head J by the action

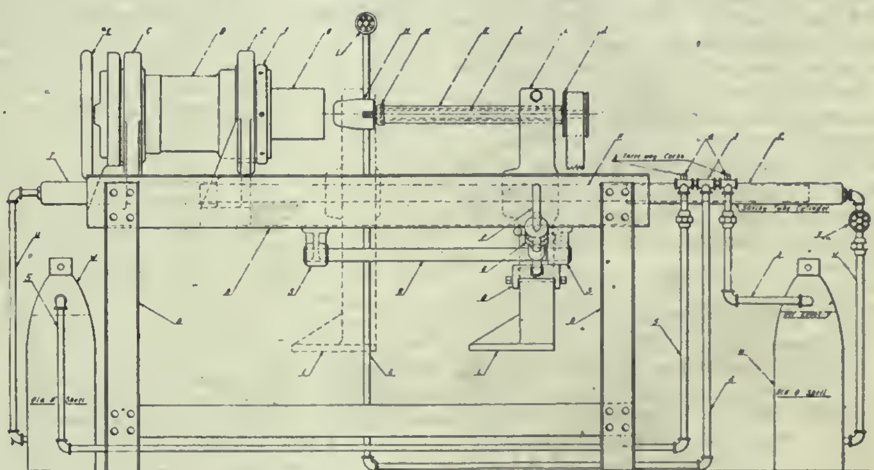

FIG. 11. GRINDING BORE OF 6-IN. SHELL.

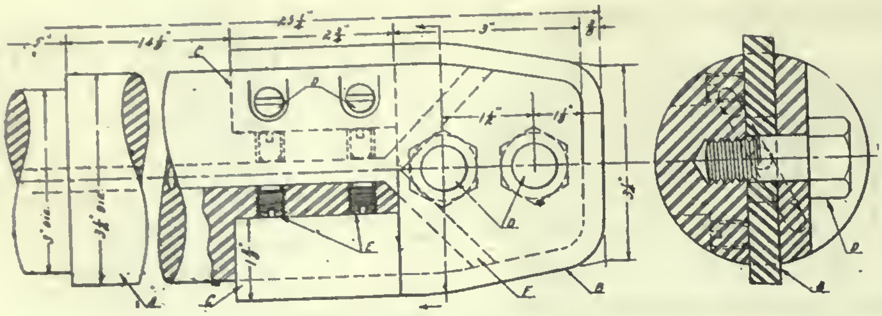

FIG. 12—BORING BAR HEAD

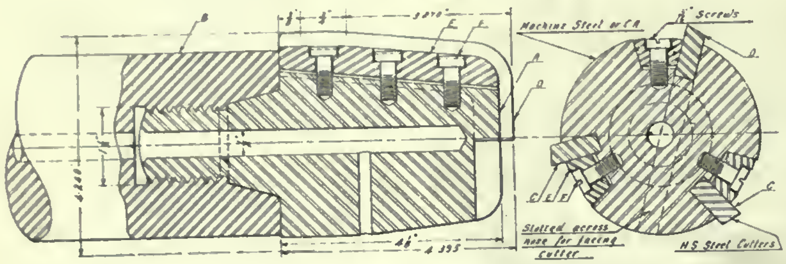

FIG. 13—FINISH BORING BAR.

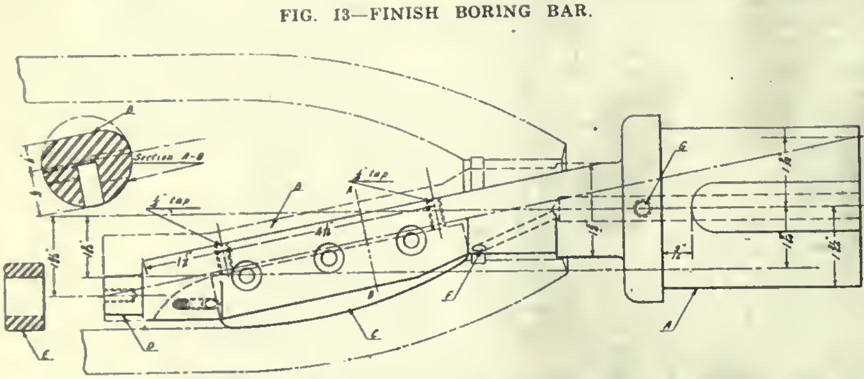

FIG. 14—INTERNAL PROFILING TOOL. WATEROUS ENGINE WORKS.

of the spring P against the nut M which is locked on the screw K, which in turn passes through the sliding piece L. The adjustable screw N serves as a positive stop when the desired position of the cutter is attained. The retainer O is securely bolted to the main holder by means of the bolts Q. A small groove R in the forward end of the cutter allows the cutter to come back against the stop S, and when in this position the cutter is practically in the center of the bar, leaving the same free to be removed from the shell without removing the holder from its fixed position.

GEOTHERMIC STEAM GENERATION

The remarkable achievement of successfully utilizing underground volcanic heat for the generation of power in the neighborhood of Lardarello, Central Tuscany, Italy, naturally suggests the possibility of applying the same method in other localities. Such utilization of the internal heat of the earth, however, is dependent upon exceptional physical conditions, and it has occurred to an American engineer, Mr. Nathaniel B B. Wales, that these conditions could be produced artificially. The increase in temperature of the earth's strata in proportion to its depth shows a mean average for the entire earth surface of one degree Fahr. for every 55 feet of depth. There are many regions, however, where this increase in temperature is far exceeded. Hundreds of areas are to be found in the United States where the temperature rises one degree for every 20 or 25 feet of depth. There is a locality near Boise, Idaho, where three wells driven to only 400 feet yield 800,000 gallons of water daily at a temperature of 170°.

It is Mr. Wales's plan to sink a well-casing wherever the geothermic condition are favorable until a stratum of high temperature, say 350° to 450° Fahr. or higher is penetrated. Surrounding this shaft a number of other casings would be sunk. Water would be injected into the heated stratum through the central well-casing, and the head of the water would cause it to percolate through the surrounding strata, from which it would absorb heat and be converted into steam. The steam would then rise through the circle of well-casings surrounding the central water shaft, and could be employed for power or heat. In this way a large zone embracing several acres could be utilized to form the active heating surface, drawing heat through the contiguous rock from an enormous radiant rock contract and allowing an inflow of heat from millions of tons of the earth's mass. The permanence of such an evaporative surface is amply proved by the maintenance of hot artesian wells, which are to be found throughout the world.

There are many areas in this country where borings not over 5,000 feet would give the necessary temperature, and others of 1,500 feet or less would supply all the heat required. In some places thesteam generated might have to be used indirectly because of the earth salts held in suspension; but no doubt these salts could very profitably be recovered and would add to the value of the instillation.—Jour. Frank. Inst.

BUREAU FOR INVENTORS AT WASHINGTON NOW

The following statement is autthorized by the War Department:

In order to secure prompt and thorough investigation of inventions submitted to the War Department an "Inventtions Section" has been created as an agency within the General Staff. All inventions of a mechanical, electrical, or chemical nature submitted to the War Department for inspection, test, or sale are now considered by this section.

May be Sent by Mail

Inventions may be sent by mail or may

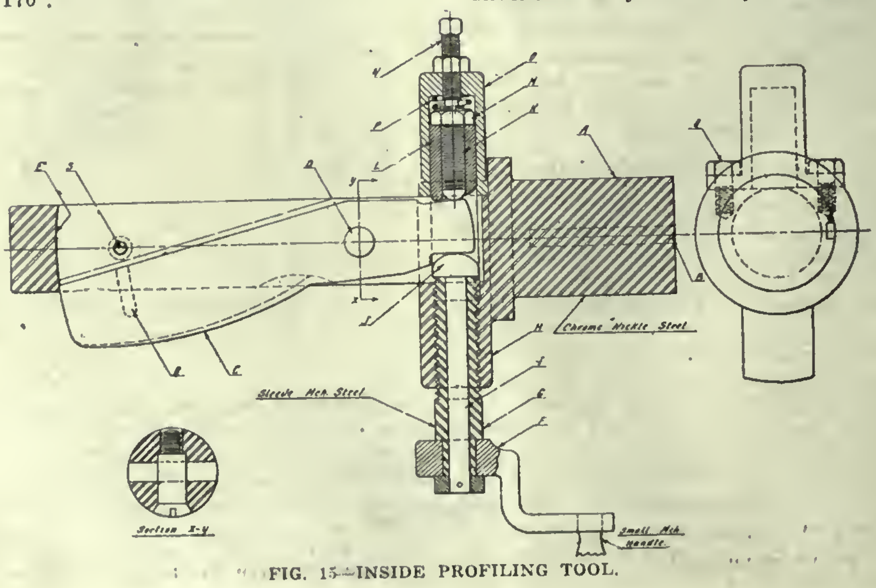

FIG. 15—INSIDE PROFILING TOOL.

be submitted in person, accompanied by written descriptions or drawings. They go first to an examining board having technical knowledge of the classes of inventions they handle, whose investigations determine whether the inventions have merit. Those with merit are referred to the Advisory Board, which determines in each case whether it should be put in the hand of some of the numerous testing and developing agencies, or if it should go to one of the staff or supply departments for test and consideration of its adoption, and final acquirement of title if such action is desirable.

When completed the board will have 12 to 15 members to cover fully all of the various technical problems which may come before it.

Assisted by Agencies

In testing and developing inventions and in considering problems presented by staff departments, the Advisory Board works in connection with a number of agencies. Among them are the following: Research Council; Bureau of Standards; War Committee of National Technical Societies (this committee consists of two members detatiled from each of the 10 important technical societies in the United States); laboratories and shops of the staff and supply departments of the Army; Patent Office; Aircraft Production Board; all Army Service Schools; C. L. Norton, Massachusetts Institute of Technology, Cambridge, Mass.; Dr. Charles P. Steinmetz, General lectrical Co., Schenectady, N.Y., etc.

Information for Inventors

Any person desiring to submit an invention for consideration, test, sale, or development should do so by letter, giving in order the following information: Name and object of the invention; any claim for superiority or novelty; any results obtained by actual experiment; whether the invention is patented; whether remuneration is expected; whether the invention has been before any other agency; whether the writer is owner or agent; the number of inclosures with the letter. A written description and sketches or drawings of sufficient detail to afford a full understanding of the cases should also be submitted. Should the invention be an explosive or other chemical combination, the ingredients and processes of mixture should be stated.

The Inventions Section will not bear the expense of preparation of drawings and descriptions, nor advance funds for personal or traveling expenses of inventors.

All Matter Confidential

Any matter submitted will be treated as confidential. The inventor will be notified of each step taken during the investigation of his invention. All communications should be addressed: Inventions Section, General Staff, Army War College, Washington, D.C.

AT ONE TIME ALL THE FILES IN USE WERE TURNED OUT BY HAND

THE MANUFACTURE OF FILES

By Mark Meredith.

For many years files were made entirely by hand, and at the present time the best files are still made in that manner. The file may be called a metal-cutting or abrasion tool, and it removes the metal by means of a series of sharp-edged parallel ridges, all inclined at an angle of about 50 degrees to the axis of the tool. There are numerous types of file differing in fineness of cut, and these are all divided into two broad classes of "double cut" and "float cut," or a "single cut." The former have two rows of cutting edges equally inclined to the axis and the latter have only one. In preparing the files steel blanks are first forged which have been previously sheared or rolled to the section required for the tool. This blank is, of course, of soft steel, and it is held on the anvil by means of a strap which passes round the tang and is held down by the foot of the operator. If the underside has been cut already, or is not flat, it is protected from damage by interposing lead or pewter as a soft support.

Then, using a chisel which is rather wider than the blank, the operator makes a series of cuts parallel to each other and at the proper angle. The hammer is chosen with great care to be of such a mass as to cause the burr from each cut to rise to the right height. The distance of one cut from the next is gauged by resting the inclined chisel against the last burr when cutting the next. By increasing the slope of the chisel the distance apart of the burr is increased and vice-versa. It is obvious that the greatest skill and practice is required to strike the chisel with the right force, and to keep its inclination constant over many hundreds of cuts. The height of the burrs as well as their distance from each other governs the fineness or coarseness of the cut. In the ordinary double-cut flat file there are 6 degrees of fineness respectively, called rough, middle, bastard, second cut, smooth, and dead smooth. Float-cut files are made in the rough, bastard and smooth varieties. In making double-cut files the first series of cuts are smoothed over very slightly before making the second series. Lancashire used to make the best files, and even now no place can compete with it for the finest files, such as watchmakers use. There is a file that has been made in Lancashire on which there were 300 cuts to the inch.

The rasp cuts in virtue of a number of triangular shaped projecting burs distributed over its surface. These are made with a three-cornered pointed punch or chisel. They are distributed as evenly as possible, the great object of the file-cutter being to arrange that one cut shall not come behind the other. There is thus great skill in arranging by the eye a pattern in which the number of cuts per square inch shall be uniform and yet in which they are rightly and irregularly placed relative to the axis of the tool.

Rasps, again, are made in rough, bastard and smooth cuts.

The wide use of aluminum has brought into use files of the "dreadnought" type. In these the cut is single and is normal to the axis, or nearly so. It is very coarse and the teeth are deep and triangular in section. As a rule they are not straight, but are shaped in arcs or circles arranged parallel to each other. This coarse type of file is necessary because the aluminum being soft rapidly clogs the teeth of the ordinary file, making the edges so that they will not cut. For the purpose of filing up metal patterns, often on awkward concave surfaces it is best to take old files, and having softened them, to cut straight dreadnought type teeth on them with a three-cornered file. The files are then bent to suit the cavities and corners which have to be worked, and are rehardened by heating and plunging into oil. In this way a most ingenious set of tools can be made to perform all sorts of impossible jobs with ease and accuracy.

Returning to the orthodox file cut in the soft steel blank, the next operation is to straighten the file out accurately. It is then hardened, the teeth being protected from burning in the heating process. After hardening the quality of the cut is improved by exposure to a blast of fine sand.

Numerous attempts have been made even in the eighteenth century to devise machines to replace the hand file-maker. These all attempted to imitate his action by means of an arm carrying a chisel, the latter being struck by a hammer, which is operated mechanically. The successful machines of the present day carry the blank on a table which advances very slowly under a chisel or hammer which reciprocates rapidly. By varying the rate of the transverse of the table the coarseness of the cut can be altered. But it still remains a fact that the hand-operator can make the best file, and this is attributed curiously enough to the advantage of a certain amount of irregularity in the teeth of the hand-cut file which it is very difficult, if not impossible, for the machine to imitate.

"Dear Clāra," wrote the young man, "pardon me, but I'm getting so forgetful. I proposed to you last night, but really forgot whether you said yes or nor."

"Dear Will," she replied by note, "so glad to hear from you. I know I said 'No' to someone last night, but I had forgotten just who it was."

In response to many inquiries from private persons as to the desirability of saving and selling old tin cans, the Department of Agriculture says it has been told by a detinning company that cans free from rust and foreign matter are worth $12 a ton, f.o.b. factory. It takes from 7,000 to 8,000 cans to weigh a ton, and the company says it is not advisable to collect the cans except in large towns.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

THE "ALL-ANGLE" GRINDERS BROUGHT OUT AND MADE IN TORONTO FACTORY

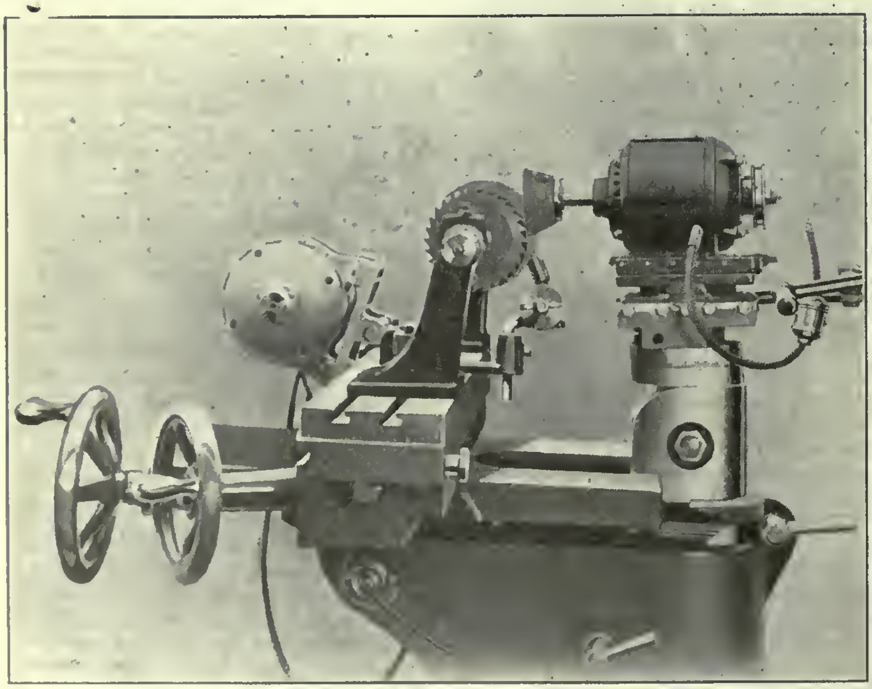
The "All-Angle" universal grinder which has been perfected by W. J. Rennie, superintendent of the Toronto Type Foundry Co., Toronto, and is being built by this concern, is a new tool embodying a number of interesting features. The outstanding feature is the large variety of work that can be done on this grinder without extra attachments. All angles and tapers can be got by adjusting the grinding head and there is no necessity for using internal, cylindrical or universal attachments, thereby eliminating a large tool cupboard and also effecting a great saving in time in setting up the grinder for working. This grinder can be placed in any position in the toolroom as no belts or countershaft are necessary. The machine has independent motors which can be run on a lighting circuit. The accompanying illustrations show the general design of the grinder and location of attachments for certain classes of work. The grinding head is graduated to obtain any required angle in vertical or horizontal positions and by this means extremely accurate work can be obtained.

The grinding head consists of a motor mounted on a sliding fixture which can swivel on the drop head. The drop head is constructed so that it can be turned round to any angle as shown on the graduated scale or can be dropped down, or tilted over also to any angle as shown on another graduated scale at the back. The motor spindle which runs at 10,000 r.p.m. carries at the front end an external grinding wheel, while at the back end of spindle is a "C" attachment for surface or large internal grinding; mounted on top of the motor is a bracket carrying a belt-driven spindle running at 30,000 r.p.m. This carries an "A" attachment for small diameters. The bent crank operates the sliding fixture to adjust the grinding head in position and there is also a screw for fine feed. The drop head can be locked in any position.

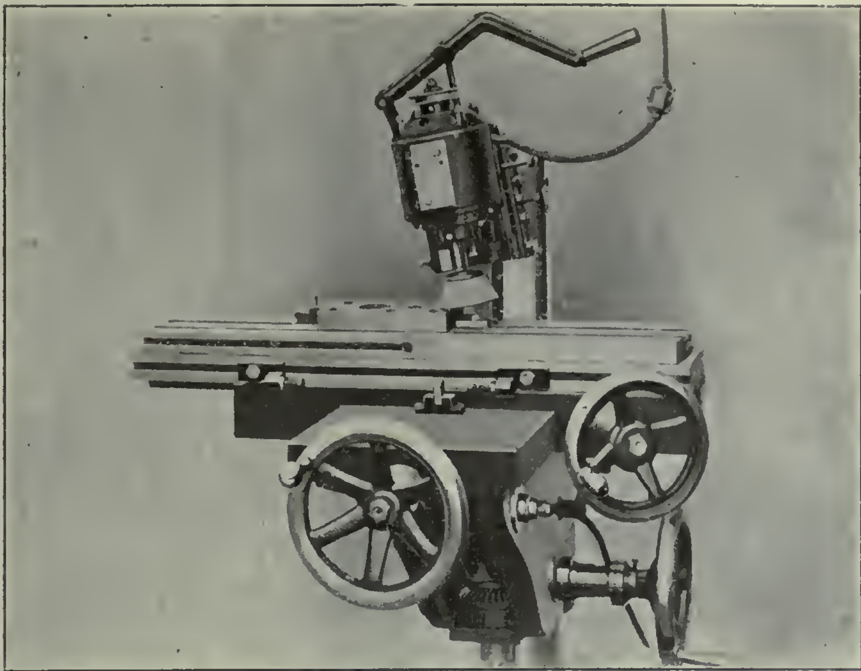
The table is in two parts, upper and lower. The lower part works in slides while the upper works on a pivot and can be set at any angle up to 10 degrees from zero either way; the angle being noted from the graduated scale at one end. The table is traversed by means of the upper hand wheel at the side and is provided with stops at the front fastened in a groove. The hand wheel has a graduated scale. The drive head can be equipped with a drive plate or chuck, or used as a headstock. When used as a drive head, it is driven by a motor attached to the table. Both drive head and motor are equipped with S K F ball bearings. The table also has a tailstock for certain operations. The centres will allow for a swing of 11 inches. The in and out motions of the table are operated by the hand wheel at the front. This wheel has a graduated scale for feed control. A useful attachment is the universal finger or tool rest. This attachment can be set in any position and at any angle.

The knee upon which the table os mounted can beswung around to any angle, the pillar having a graduated scale for noting the angle. The knee is operated in a vertical direction by means of a telescopic screw, by bevel gearing. The type of screw provides for a longer range of travel without measuring the height of the machine. The screw operating gear has ball bearings. The knee is operated by the lower hand wheel on the left side. The base of the grinder is box section and has four plugs, one at each corner for the motor connections.

For external grinding the work is held on an arbor or drive plate and the grinding wheel placed in any required angle or position. The machine is particularly well adapted for grinding steel profile gauges for shells owing to the peculiar form of the gauge and great accuracy required. For this work the former and work are held on an angle plate attached to the table and the grinding head placed in a horizontal posi-



GRINDING A MILLING CUTTER, HELD ON AN ARBOR. THE GRINDING HEAD IS TILTED TO OBTAIN CLEARANCE, THE EXACT CLEARANCE BEING SHOWN ON A GRADUATED SCALE.



GRINDING FACE OF A STEEL DIE. THE GRINDING HEAD IS SET OVER INTO THE VERTICAL POSITION TO NINETY DEGREES. THE MOTOR IS THEN TILTED TEN DEGREES TO GIVE A CONCAVE SURFACE TO THE DIE.

tion. The slide is left free to allow the former to raise and lower the grinding head. When grinding blanking dies, the table is set at zero, and the grinding head is set over into the vertical position to 90 degrees. The motor is tilted to give a concave surface to the die.

For internal grinding the work is held in a chuck or bolted to the drive plate. The grinding head is used in a horizontal position and turned round so that either the "C" or "A" attachments can be used, according to the diameter of hole to be ground.

The following specification gives some of the principal dimensions and features of the "All-Angle" grinder. The grinding motor is of the universal type built in any voltage from 80 to 300. The main spindle speed is 10,000 r.p.m., which is the same for the "C" attachment for internal and surface grinding. The speed of the "A" attachment for internal grinding of small diameters is 30,000 r.p.m. The driving motor is a variable speed universal ball bearing motor with controller for 20 speed variations. The controller is attached to the knee under the table.

Longitudinal movement of table, 18½ inches.

Cross movement of table, 7 inches.

Vertical movement of table below the grinding wheel centre, 19 inches.

Surface grinding vertical movement with grinding head in vertical position, 5½ inches.

Will take work 15 inches long and swing 11¾ inches.

Surface dimensions of table, 28 x 5½ inches

Internal grinding, either straight or taper, from 5/16 to 10 inches in diameter and up to 6 inches in depth.

The table swings around the column through 360 degrees.

The grinding motor swings through a vertical plane of 90 degrees.

The grinding motor will slide in a plane parallel to its base to a depth of 5¾ inches, operated by feed lever.

The grinding motor, swivel base, and sliding base can be revolved 360 degrees. The grinding motor will revolve through 360 degrees in a plane parallel to and above the sliding base.

Floor space, 48 inches by 54 inches.

Net weight, 875 pounds.

Shipping weight, domestic, 1,000 pounds. Shipping weight, foreign, 1,250 pounds.

Shipping measurements, domestic, 5 feet by 2 feet 10 inches by 3 feet.

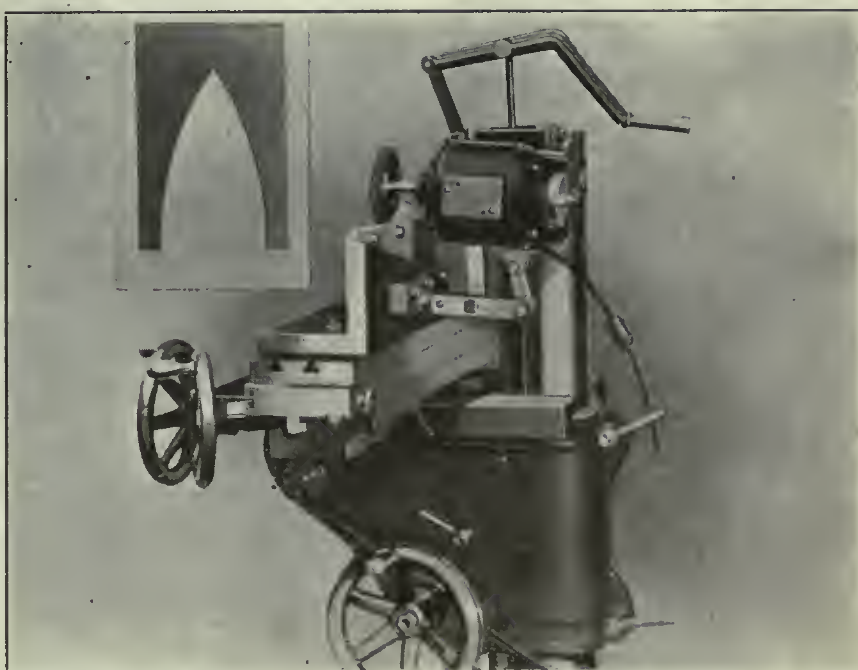
Shipping measurements, foreign, 4 feet 9 inches by 2 feet 4 inches by 3 feet 3 inches.

TRIPLE GEARED ENGINE LATHE

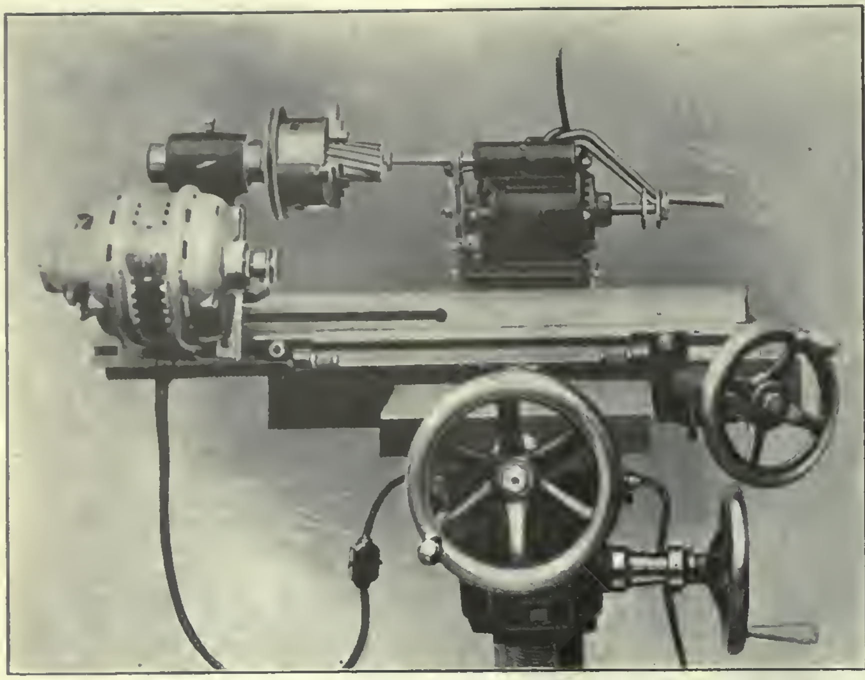
The triple geared engine lathe shown in the accompanying illustration, built by the Canada Machinery Corporation has been redesigned and improved. The lathe which is of strong construction is made in two sizes 36 in. and 42 in. swing.

It is equipped with four step cone and back geared drive and in addition with a triple geared drive direct to face plate. This arrangement combines great driving power and an ample number of spindle speeds. This lathe is a modern high speed tool of great strength and extreme accuracy. It is provided with a deep bed, giving maximum stiffness under cut. By means of feed box immediately below the headstock three changes may be instantly obtained. The saddle is substantial throughout with great strength in the bridge—the bridge having a bearing on the flat surface inside the V, in addition to the two V bearings. The machine in detail is as follows:

The bed is unusually deep and rigid, and is thoroughly braced with cross ribs of box section. It is provided with three inverted V's of liberal proportions. The headstock and the tailstock each rest on one V and one flat surface, and the saddle bears on two V's and also on the flat surface. The brackets attached



GRINDING ON SIDE OF A HARDENED STEEL PROFILE GAUGE FOR 4.5 H.E. SHELLS. NOTE THE POSITION OF THE FORMER AND WORK ON THE ANGLE PLATE. DUPLICATE GAUGES OF INNUMERABLE DESIGNS CAN THUS BE PRODUCED.



GRINDING THE HOLE IN A SPIRAL MILLING CUTTER. THE GRINDING HEAD IS SET OVER THE TABLE UNTIL THE "A" ATTACHMENT IS IN LINE WITH THE SPINDLE.

to the bed are made with a tongue fitting a groove in the bed, and the rack is securely screwed and dowelled to the bed.

Headstock throughout is unusually massive and is of the four-step cone triple geared to face plate type. It is equipped with split phosphor bronze bearings. The spindle is turned from our special high carbon spindle steel and has a hole bored from the solid throughout its entire length. It is accurately turned and carefully ground to size. The cone has four steps of extra wide faces to enable wide belts to be used, and in this particular we have more power in our lathes than found in other engine lathes of similar sizes. The saddle is large and rigid, having a bearing its full length on the V's. The apron is of the double walled type, there being a double bearing for all pinion studs. All gears in the apron are of steel. The handwheel is not geared directly to the rack on the bed but indirectly through a reducing intermediate gear to facilitate the movement of the saddle. When the lathe is used for screw cutting the rack pinion is drawn out of mesh by a knob handle on the end of the pinion stud.

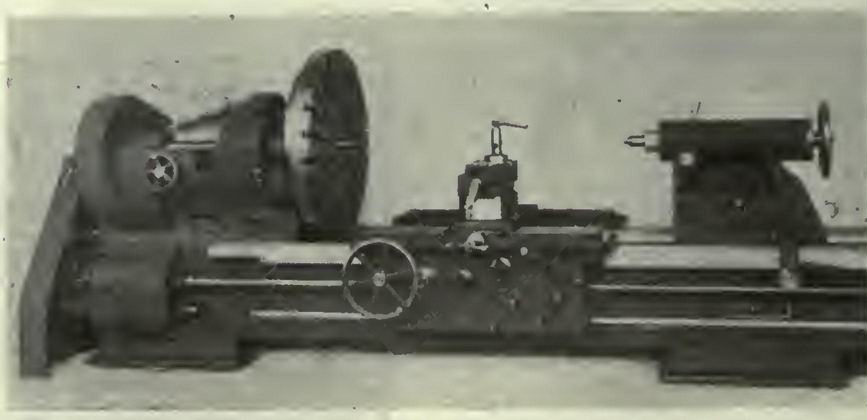
Three changes of feed are obtainable through the feed box on the bed below the headstock. By changing the gears on the head and quadrant plate any desired feed may be obtained. It is impossible to engage either the automatic cross or longitudinal feeds when the machine is set for screw cutting, or vice versa. The thread on the lead screw is used for screw cutting only. The feeds may be instantly reversed in the apron by a convenient lever. The saddle is securely clamped when using the cross feed. The lead screw is reversed for right and left hand threads by means of the reverse plate on the head. The feed gears in the head are arranged so that quick threads up to 8 in. lead can be cut by putting on gear to suit.

Thread chasing dial, for indicating correct point for engaging nut for thread cutting, is provided on the carriage, obviating the necessity for stopping the lathe when screw cutting. Micrometer adjustment is provided on the handles of the cross screw, graduated in 5/1000's and 1/32's of an inch. Compound tool rest is provided, with base graduated in degrees.

Tailstock is rigid and heavy, and is clamped to the bed by two bolts conveniently situated. It is also provided with a pawl engaging in a rack cast in the bed, which serves to take the heavy strain of the clamping bolts and gives a positive brace when the machine is engaged on heavy work. The pawl is operated by a rod convenient to the operator. The shape of the tailstock is such as to permit compound rest to be set at right angles without interfering. The spindle is graduated in inches and fractions of an inch for use in boring. The tailstock is adjustable across its base by means of a screw to permit of its being set over to turn taper, the base bebing graduated for this purpose.

Standard equipment includes countershaft with two friction pulleys, necessary shifters, follow rest, steady rest, face plate, change gears and necessary wrenches. Special attachments, such as taper attachment, turret on the bed, or saddle, turret tool post, etc., can be furnished at an extra price when so desired. Motor drive.—The lathes can, if so desired, be arranged to be driven direct by constant or variable speed motor, or by single pulley drive.

The distance between centres, 14 ft. bed, for the 36 in. lathe is 6 ft. 1 in., and for the 42 in. lathe 5 ft. 11 ins. The weight of machine complete with 14 ft. bed is 15,500 pounds and 17,000 pounds respectively. For both machines the width of belt on cone is 5½ in., steps on cone 4, number of speeds to spindle 24, diameter of front spindle bearing 6 in., and length 10 in., diameter of rear spindle bearing 5½ in., and length 7 in., diameter of hole through spindle 3⅛ in.



36 AND 42-INCH TRIPLE GEARED ENGINE LATHE

BEVEL GRINDER AND AUTOMATIC MILLING SAW SHARPENER

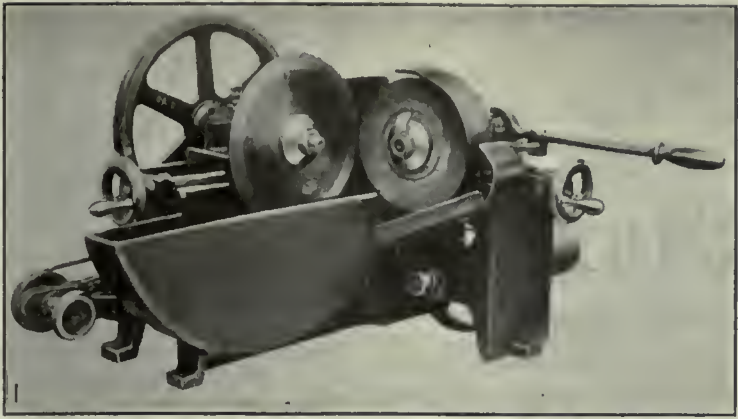
The accompanying illustrations show two machines recently marketed by the Machinery Company of America, Big Rapids, Mich. Figs. 1 and 2 show front and back views of the bevel grinder. This grinder is suitable for theg rinding or sharpening of circular cutters or knives commonly used on meat paper, cork cloth, etc., and will grind from within 10 inches of centre to within ¾ inch. Thus a cutter of 4 inches diameter may be bevel ground to a maximum width of 1¼ inch.

General Description

The operation of the machine is very simple and all adjustments will be readily understood. A hand adjustment is provided for a quick centering of the cutter, according to its diameter, for proper contact with the grinding wheel. A handwheel adjustment feeds the grinding wheel to or from the cutter, during the grinding process. A hand lever affords lateral movement of the grinding wheel across the surface of the cutter. The angle or degree of the bevel grind is adjustable to suit the requirements of cutters of different gauges, diameters, etc. The grinder is equipped with a water tank so that the grinding is done wet and tendency to heat and impair the cutter is avoided. An adjustable stop or back rest of fibre is mounted behind the cutter opposite the grinding wheel, which supports the cutter rigidly and prevents chatter or improper vibration. A guard is provided for the grinding wheel to prevent it throwing dust and water.

The grinding can be done very rapidly and satisfactorily, and if a cutter is but slightly dulled the time required for the grinding is negligible.

The machine is provided with every adjustment necessary to afford a bevel grind of any width up to 1½ inches on cutters not over twenty inches in diameter, and that sufficiently exceed a 3-inch minimum diameter to permit a bevel grind of required width.



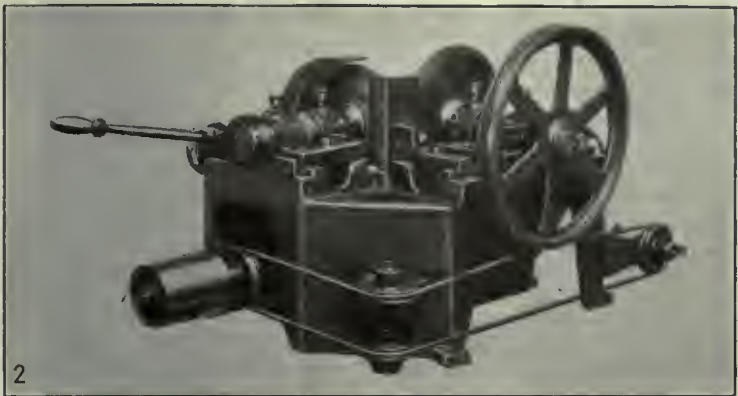


FIG. 1—FRONT VIEW OF BEVEL GRINDER. FIG. 2—BACK VIEW OF BEVEL GRINDER. FIG. 3—AUTOMATIC MILLING SAW SHARPENER.

The automatic slitting or milling saw sharpener shown in Fig. 3 was designed especially for regrinding and recutting slitting or milling saws 2 inches to 10 inches in diameter, usual spacing, and is especially well adapted to the reclaiming of very thing slitting saws with fine tooth spacings, which in the past on account of having no efficient means of re-sharpening have been discarded. With this grinder they may be resharpened repeatedly until the entire value is received from the blade.

Utility

The grinding of the teeth is absolutely uniform; the cutting points are kept perfectly "in spacing,' equalizing the strain on the saw, and keeping them always sharp and in perfect condition, insuring smooth, fast-cutting with reduced friction and heating of the blade in the cut. The action is full automatic, requiring very little attention on the part of the operator after being placed in operation and has a very rigid, strong body mounted on a substantial pedestal, bringing it up to a convenient height to the operator. All essential working parts are entirely enclosed in the body, fully protected from all dust, dirt and other foreign matter. All moving parts are provided with ample adjustments for taking up wear and insuring absolute accuracy of action and durable service without deterioration. The very best of workmanship is put upon this machine throughout. Any standard shape or spacing of tooth may be readily obtained by hand wheel adjustments conveniently located to the operator.

QUICKLY ADJUSTABLE BENCH VISE

The Barnett Foundry & Machine Company, Irvington, N.J., has just brought out a machinist's bench vise under the name of "Winans' New Idea Vise" that

QUICKLY ADJUSTABLE BENCH VISE.

embodies several novel features. Reference to the illustration herewith presented will show its general characteristics. It will be seen that the old fashioned screw and lever has been replaced by a pawl and rack. This is actuated by a handle on an eccentric shaft, which will exert a pressure many times that possible with a screw.

The adjustments from zero to maximum are made instantly with one sliding movement. The pawl eccentric and sliding jaw form a toggle joint, bringing the greatest pressure to bear on the top part of the jaws, causing the work to be clamped tightest at the working part. The moving member of the vise slides away from the operator and there is no handle between operator and the vise. The gripping plates are hardened and ground, and the rack and pawl are also hardened steel.

A feature of importance is that the whole vise may be removed from its swivel base and taken to surface plate, drill press or milling machine for continuous operations, since the base of the vise is accurately machined to right angles with the jaws. These vises are made in standard sizes of jaws from 3 inches to 8½ inches, and openings of 3½ to 12 inches.

A certain learned Queen's counsel was arguing a commercial case before a learned judge. In doing so he had occasion to speak repeatedly of an "eccentric," and the judge at length asked him what an eccentric was. The magistrate said he was familiar with the term as applied to individuals but not to things. The Queen's counsel at once complied. "An eccentric," he said, "is a circular disk whose centre is not in the middle."

A Strike That Should Not Have Been

THE business of a good many cities was interfered with when the postmen went on strike. Mails were held up, important orders cancelled and no small monetary loss resulted.

The department at Ottawa should never have allowed that strike to come to pass. The fact that it did was evidence of administrative incompetence.

The men were underpaid—grossly so, and the trouble was on the horizon a long time before it broke.

If any department of Canada's government is due for a rattling of dry bones, the finger points to the post office department.

Mistaken Idea of Secrets of the Trade

DID you ever come in contact with the mechanic who was always afraid that some person else in the shop would learn his ways and methods of doing certain jobs? The chances are that if you have had much experience you have met this chap several times over.

He has failed and failed miserably to grasp the idea that giving away knowledge does not make him any poorer, neither does the withholding of it make him any richer.

There are men to-day who might have developed into real good mechanics had it not been for the "stand pat" type of mechanic with whom they became associated early in their experience. This mechanic, perhaps a foreman, failed to make the trade interesting. He kept his ways and devices under a bushel. He always made it a plan to let the new man "go in and find out for himself." He may have done it to try and develop initiative in the men under him, but it does not work out that way. Apprentices came to him, they served their time, and they went their way. They might have been experts—they might have left that shop qualified to go in any place and begin work—they might have gone out knowing that they were "real mechanics." But they didn't. They may have dropped into better environment later on, when they would have a chance to develop the real things of the trade. But the fact remains that there are shops, and plenty of them, where the mechanics have not yet learned the great truth that it pays handsomely to make the young apprentice a capable hand before he leaves the shop.

There is another phase to this same situation, and that is the experience that mechanics can pass along and put on record through the medium of such papers as CANADIAN MACHINERY. The mechanic who has had experience that makes work easier, that brings better results for the firm, has a responsibility, and that responsibility is to try and bring others up to the same standard of efficiency he himself has reached. Firms are often forced to spend hundreds and thousands of dollars in experimenting to find out what some other group of men already know. The result is that industry—viewed from the larger scope in the national field—loses, and a tremendous amount of energy is wasted, all because the mechanic with the knowledge saw best to keep it to himself.

Remember this. You are not going to be any poorer because some person else knows as much as you do. It is not going to cut the ground from under your feet because you help some other chap to get the training that will enable him to hold down a good position and do the work well. Your reward will be greater than any that a paper can pay for your material. It will be in the form of satisfaction in having helped some person to make two dollars where he was making one, and in making a good mechanic out of the chap who is now being pitchforked out of the shop as a handyman.

Alberta And Its Big Problem

ALBERTA coal is surely having a merry time trying to make its bow to the people of Winnipeg. If all the energy that has been spent in investigating and reporting had been applied directly to the production and application of coal there would be quite a few bins filled to the ears by now.

Here's the way the situation is summed up in one of the numerous reports that have been issued:

> In this connection, it is claimed that the majority of Winnipeg dealers are absolutely hostile to Alberta coal, while a few who are genuinely boosting it are carried away by their zeal and led to extravagant claims which must result in dissatisfied consumers.

Now the thing most necessary seems to be a quota of dealers who will have just the right amount of thuse in their system. They must not blow off too hard or the consumers will expect too much. Neither must they be too frigid or the frigidity is likely to extend to the order books. Apparently it has not occurred to them to let the dealers get out and peddle coal like they used to pitchfork real estate bargains around.

But apart from what the people of Winnipeg think of Alberta coal, or what the operators think of the people of Winnipeg the fact remains that it's a long cry between the present production of Alberta mines and what should be forthcoming to meet the winter needs of Western Canada. One report just issued has this to say:

> That a short crop of wheat in Southern Alberta, and Western Saskatchewan will reduce the amount of coal consumed in that area.
>
> That the short crop will release much labor for the mines this fall.
>
> That the short crop will release sufficient rolling stock from the normal traffic in wheat to carry Alberta coal Eastward through the crop moving season, thereby averting the danger of a calamitous shortage of fuel in Manitoba.
>
> That labor conditions are intolerable, alien miners, instead of the operators, are actually operating the mines at present. In this connection the department of labor and the mine administrator are severely criticized, it being declared that their method of keeping the mines operating is to grant every demand, no matter how unreasonable, made by the miners.

When it is remembered that the West has about three months left before the coal burning season starts, it's a mild statement to remark that the situation west of the Great Lakes looks serious.

OUR idea of a man with great foresight is the chap who whacks moths out of his winter underwear while the thermometer shows 95 in the shade.

HAS FAITH IN CANADA

American Has Developed a Nice Selling Business For Steel Trade in Canada

IT seems to have been the trend in recent years, and especially in connection with the industrial development of Canada, that the drift of steel men has been northward. This is true in connection with the actual operations in the steel plants as well as with the sales end of the steel and iron business.

Ralph B. Norton, Canadian agent of the Kayser, Ellison & Co., Ltd., Sheffield, England, was born in Essex, Mass., in 1880, his parents having come previously to that country from England.

RALPH B. NORTON.

Shortly after leaving school he entered the steel business in the employ of the New England agent of Kayser, Ellison & Co., Sheffield, and the Crucible Steel Co. of America. For 13 years he was connected with this branch through its various offices, becoming conversant with all lines of steel and making a special study of alloy steels. He travelled extensively through Eastern United States and became one of the best known steel salesmen in that section.

While in Sheffield in 1913 Mr. Norton accepted a commission to open a branch for Kayser, Ellison & Co. in this country. Although this mill was one of the largest and most progressive in Sheffield, it was not so well known here, but in five years' time by untiring work, perseverance and up-to-date methods he has brought this new branch to a par with the older established English firms.

On the outbreak of war and the curtailment of English shipments, his acquaintance with the American steel manufacturers and sources of supply enabled him to take care of his ever-increasing trade. Mr. Norton is of a genial disposition, and has won a host of friends both in the East and in Ontario, where he contemplates opening a second branch.

He became greatly attached to Canada, and is full of praise for the way our Canadian manufacturers have risen to the call for greater production in every line. He is confident that any difficulties arising in business conditions through adjusting ourselves to times of peace will be met in the same unconquerable fashion.

SCORES THE "DEAD ENDS"

Invesigation Into Causes of Some of the Recent Fires That Have Occurred in Toronto

THE deputy fire marshal for Ontario, Geo. F. Lewis, conducted an investigation into the Thor Ironworks fire. The matter of its possible origin was gone into at some length, also the methods employed in fighting it, water pressure, etc. Considerable evidence was brought out regarding the employment of foreigners and the need for rigid care in this regard.

The part of the greatest importance, however, was that applying to the fire fighting forces and the supply of water. The "dead end" situation in water mains is one that probably exists in every city, and what applies in Toronto will have equal force and warning in other centres. One matter that was brought out in the investigation was the fact that it was quite possible for foreigners or any person, for that matter, to enter certain parts of the works at any time, a practice, which in the opinion of the investigators, should be curtailed as far as possible in times like these.

The Shortage of Water

In connection with the actual circumstances of the fighting of the fire, Lieutenant Mitchell on being examined stated that the first line of hose was connected with the hydrant at the Thor Iron Works gate, and with that he fought the fire from the water front side till their hose caught fire and they were cut off. It was shown that for about six minutes the pressure on the first line of hose was alright, but as soon as additional lines were laid they took away the pressure. It was even established that when the pressure started to go down they could only hit about the bottom of the second floor and it continued to drop until their hose was burnt and they were cut off entirely. The department that was fighting the fire at the Thor Works had to depend upon the Bathurst and the Spadina main. The hydrant at the foot of Spadina about fourteen hundred feet distance was also used. It is on a five-inch main and also a "dead end," so that all the water the fire department had to fight the fire with was from 2 six-inch mains on "dead ends." The Spadina Ave. connection wasn't much good as a fire fighting proposition either on account of the friction. There would be very little pressure after the water got through the 1,600 feet of hose running from Spadina Ave. to the scene of the fire.

The Evidence of the Chief

The chief of the Toronto Fire Department himself in giving evidence said, "that the big trouble was we didn't have enough water. The firemen were hampered by the lack of hydrants, bad roads, as well as lack of water, together with the necessity of laying long lines of hose." The chief also added that there was no reason why that plant would have been entirely burned like that if we had had roadways and the water. It was also brought out by the chief that he had applied to the Water Works Department of Toronto for blue prints showing the location of hydrants and sizes of mains in the various streets throughout the city, and had not yet got them and was thus without the proper scientific knowledge from a fire fighting standpoint of what he was up against.

At one time during the investigation Mr. Lewis, the deputy fire marshal for the Province, asked the fire chief this question: "If you had had proper water pressure at these fires the chances are it would have reduced the fire wastage enormously?" and the chief answered quite frankly to this that it would have made a wonderful difference.

William Corbett, district chief in the fire department, in his evidence went on to show that the fire department was badly hampered on account of bad and crooked roads, and insufficient water supply in fighting the Thor Iron Works fire, together with the delay caused by laying

MARKET DEVELOPMENTS

War Industries Get the Preference

Firms Making Other Lines Are Having Hard Time Securing Supplies From War Trade Board—Small Chance of Any Material For the Commercial Users of Steel

THE Canadian manufacturer who is not working on war orders is not faring well in some cases, and the future has not much in store for him if he has to come to the War Board asking for supplies. True, the situation is not one that has developed over night, but the drift in that direction has been gradual and very persistent for some weeks, until now in some industrial for pig Iron had been turned down by the War Trade Board. centres it is being quite marked. Only this week one manufacturer in Toronto was informed that his request His lines are soil pipe, fittings and boilers for stoves. At present his firm has enough material on hand to run for six weeks, but at the expiration of that period he will be out if he cannot secure assistance, or turn quickly to other lines that will find favor with the War Trade Board.

There has been a feeling in the steel trade that about this time of year there would be some steel for distribution to the commercial users. It had been thought that after a three-months' concentration on war work the demands would have been overtaken. Just how far this guess is wide of the mark is shown by figures given out to-day in United States. It appears that the estimates of the requirements of the war group there for steel for the second half of 1918 will be 20 millions tons of steel, while at present the mills are only producing at the rate of about 16 million tons for that period. There seems to be little prospect of bringing production figures much past the point where they now are. From this it will be seen that there is small chance of commercial users of steel either in Canada or United States getting any supplies this year.

The fortunes of war bring many peculiar turns in the market. Only a few weeks ago the talk was about the great quantities of steel rails at Vancouver on order of the Russian government. This week in New York some 200 large machine tools are offered to the trade because they had not been shipped to their Russian orders. And it is also reported that agents from industrial and government quarters in Brazil are in American cities this week asking about the chances of securing machine tools for the manufacture of munitions to the order of Brazil.

The demand for pig iron and scrap is not satisfied in Ontario or any part of the Dominion. At American points it is being cornered for war work absolutely. A survey was recently taken in United States, as a result of which some 300,000 tons of pig were taken from non-war industries and turned over to firms that were working on essential contracts.

MONTREAL SEES NO CHANGE OF STEEL BEING SERVED FOR COMMERCIAL PURPOSES

Special to CANADIAN MACHINERY.

MONTREAL, August 1.—Continued hot weather has somewhat affected the tone of regular operations, and this is reflected in almost every line of activity, in particular, those industrial plants working on the production of furnace steel. Rolling mills and steel foundries have experienced a strenuous week owing to the continued hot wave. Machine tool trade has shown a languid tendency but the volume of business has been quiet heavy, owing to the early requirements of shell plants now under construction. Metals have had a comparatively quiet week with prices well maintained. Old materials are without feature at steady prices.

Production Slightly Reduced

As generally expected during the summer months, the output from the steel mills throughout the district has shown a falling off, and should the extreme hot weather continue this feature will become additionally emphasized during the coming weeks. Another factor that materially affects production is the holiday season when many are away from the offices and factories. Steel, both in the form of bars and billets for the recent renewal orders for shrapnel and high explosive, is being made in larger quantities. During the past few weeks it has been rumored that steel would be more easily obtained for other than essential war work, but as stated in previous letters, the situation has shown no tendency to change towards a more favorable distribution of steel; as a matter of fact the increasing demands in the United States for all classes of war supplies has resulted in reducing any quantity that might appear available for non-essential consumption. The abnormal requirements, however, make it very difficult to acquire steel for ordinary purposes, but owing to the indirect bearing that all existing activities have to the actual prosecution of the war, the business that might be termed of no importance is very hard to define. It is this condition that increases the necessity of careful supervision in the distribution of the output from the mills.

While it is possible that some action may be contemplated, on the part of the Canadian Government, in the matter of some form of price regulations, it is not taken seriously by the steel men here. The comparative volume of material that is produced in Canada to what is received from American mills, makes the regulation of steel prices here a very difficult problem, and one that could not very well be solved satisfactorily under existing conditions. Dealers here report a quiet period, largely as a result of weather and the holiday season.

Prices continue firm and unchanged on a market that is exclusively confined to war activities.

Features Developing in Metals

The week has passed without any local developments and the markets continues steady and firm. Interesting features however, are looked for in the near future owing to the movement in copper circles regarding a further revision of price, and to the uncertainty prevailing in tin, as a result of recent restrictions imposed on shipments of metal from is very heavy, exceeding the visible supply. Lack of inquiry has weakened the spelter market. Antimony is stronger with aluminum steady.

Copper.—Further agitation for another advance on copper has created a situation similar to that prevailing just prior to the last recent revision, so that the general tone of the market, if it may be termed such, is one of uncertainty, coupled with a nervousness on the part of the trade in covering their requirements. Few sales are made apart from price at time of delivery, so that those consumers with sufficient for immediate requirements are reluctant to place further orders under these conditions. Local dealers report a good business with supplies hard to obtain. Quotations are firm at 30½ and 31½ cents per lb.

Tin.—Developments at the source of supply are taking a turn that may eventually result in materially affecting present uncertain conditions, and these developments will not tend to ease the tension of the past several months. Closer regulation of shipments of Straits tin will mean a further period of nervousness, particularly on this side of the Atlantic. Dealers here report a declining supply but are able to satisfy customers for their most urgent requirements. This week's quotation show a stronger a stronger situation, the 5 cent advance placing the price (nominal) at $1.15 per lb.

Lead.—The heavy demand for lead and the evident scarcity has created a stronger undertone in this metal. Dealers here continue to quote 10½ cents but look for a stronger market.

Good Business in Machine Tools

While the present demand for equipment is not excessive, the dealers and manufacturers are actively engaged in placing machines that have been on order for some time. The rapid progress that has been made in the erection of several local munition plants, to take care of American and new shrapnel orders, has required the speeding up of machinery delivery. This equipment is coming along in good volume and it is anticipated that little delay will result after the completion of the buildings. New tools are the ones particularly in demand but very good business has been done in used equipment. One machinery house here recently disposed of the entire shell equipment of a large locomotive plant, the total value approximating $250,000. Much of this machinery was absorbed by other plants in the district. Local builders of special shell machinery are very active. Demand for all classes of supplies continues very heavy.

POINTS IN WEEK'S MARKETING NOTES

Reliable figures compiled in the United States show that the war requirements for the second half of the year will be twenty million tons of steel, while the output looks to be about sixteen and a half million tons. This would indicate that there is a very small possibility of any steel being left over for commercial users.

—

Although the story has been in circulation ever since U. S. began to manufacture war material that there was sure to be a labor shortage in the steel industry, the fact remains that at the present time in spite of recruiting, and all other drains upon labor, that the mills and furnaces are all very well furnished with labor.

—

A list of some 200 machine tools which originally sold through Russian firms, have been placed on the New York market.

—

Agents from Brazil are now in New York getting figures from dealers there on a number of tools for munition work in Brazil.

—

United States steel men are all agreed that it is not advisable to build any more furnaces there at the present time

—

As a result of a survey of the available pig iron in the U. S. some three hundred thousand tons were taken from plants working on non-essential contracts and given over to plants that were filled up with war orders.

—

Several Ontario firms have been notified that their request for a supply of pig iron have been refused by the war trade board.

—

Several of the large producers in American points have notified their old customers that if they wish to secure allottments of pig iron for 1919, they will have to get their plants into shape to handle war contracts.

—

A record is made this week in an unusual way, in that no changes are recorded in the market prices of steel or iron.

NON-WAR INDUSTRIES CAN'T GET SUPPLIES

Pig Iron Being Cut Off and Saved for Group of War Industries

TORONTO.—From time to time the statement has appeared that there was a tightening up in the supply of basic materials to the various institutions in the Dominion. Although a great deal does not appear on the surface, evidence is occasionally found which goes to show that the supply of such materials as pig iron is being dealt out to the war group in quantities in keeping with their needs. In fact it is seldom that a complaint is heard from any of these firms that they are being held up for want of material. There is a fairly good system worked out by which the War Board keeps the situation pretty well in hand.

Other firms are not faring so well. The representative of CANADIAN MACHINERY has met several outside foundrymen this week who were in the city in search of pig or good scrap. They are not being well served, and in some cases the supply has diminished to such a point that a temporary shut-down is in sight unless something comes along to relieve the situation, and that something is very uncertain at the moment.

Just to-day one firm in Toronto, manufacturing hardware supplies, soil pipes, fittings, stove boilers, etc., was turned down in its request for pig iron. This firm has enough material on hand to run along about six weeks, and unless it can go over to war work, the prospects are for a shut-down for a time at least.

Steel Prices Hold

No changes are made in any of the quotations in the steel market to-day, and indications point to a continuance of values that have been named for some days. From information received at this office it would seem that there is a fairly large amount of structural building waiting until there can be a supply of material for that purpose. Inquiries have been made at several of the firms dealing in structural steel, and the information is invariably given that it is useless to put in the order at Ottawa, for the simple reason that the War Board will not entertain it.

Conditions in United States are reflected here to a large extent. In a recent survey made of the pig iron situation there, some 300,000 tons of pig iron were found in the hands of industries that the War Board there refused to recognize as "essential." Recognition being denied them, this amount of material was confiscated and placed with firms that were working on strictly war contracts. No such action has been taken here, because supplies are hardly allowed out in proportions large enough to permit of such a situation.

Scrap Metals

There is very little trade moving in the scrap metal market this week. Dealers are keen to secure anything in the nature of good foundry scrap for the demand for it is very marked. As a matter of fact, though, users of materials that usually go into scrap in the course of time are holding to them now, as the cost of replacement is a feature that they have to consider. Railroads in Canada are following the same policy as those in the States, and they are making their stock work overtime to cope with the transportation problems that they are facing.

Although prices for copper scrap, turnings and wire advanced quite sharply in sympathy with the new fixed price in United States, dealers do not report any larger amounts coming into the market.

Occasionally the question of reclaiming tin comes up. No doubt the $1.25 per pound price at which tin is moving has something to do with the agitation to reclaim certain portions of it. There is nothing of a practicable nature in the proposal as far as this country is concerned. It would take between seven and eight thousand tin cans to weigh a ton, and the value of the cans would be about $12 at the factory, according to present prices.

In Narrower Margins

Dealing in copper is coming gradually into a smaller compass. Dealers are not able to go into the market and buy all they want. There are limits now, and they are very closely defined, with the consequence that the available supply of copper is becoming scarce.

Prices for certain kinds of copper, for special uses, are advancing very much in excess of the price for the commodity fixed by the authorities. For instance, copper in the form used by photo-engravers is a hard thing to obtain and prices on that line have been advanced quite sharply, the result being higher prices for printing illustrations, etc.

Dealers here report only one minor change in market quotations, lead having moved up a half cent per pound.

Machinery and Supplies

Machinery for munitions plants comprises the principal class of business moving now. In this connection it is interesting to note that the Leaside Munitions Co. are proceeding with the construction of a new plant for machining 12-inch shells. Orders for a considerable amount of the machinery have been placed and also the contract for the transmission equipment. Local dealers report business as being fairly good but with a quieter tendency. Express shipments continue slow and are not much quicker than freight shipments.

An advance has been made in electric weld-proof coil chain. New prices now named range as follows: 3/16 x 5, $18.25; ¼-inch, $15.65; 5/16-inch, $13.15; ⅜-inch and larger, $11.90. A corresponding increase in other sizes and qualities has also been put into effect. Practically the entire line of the Stanley Rule and Level Co.'s goods has advanced. Prices generally on machine shop supplies are holding firm, with a shortage in some lines.

BRIEF REPORTS ON SCRAP AND PIG AT BIG PRODUCING POINTS

Reports on the pig iron situation in the various industrial centres are as follows:

Pittsburgh.—The survey of the pig iron supply recently conducted has resulted in close to 300,000 tons of iron under contract to certain consumers being taken from them and given over to companies working on big war contracts.

Chicago.—The smelters in general have enough iron with which to carry on current operations but some of them are not sure how they will fare when their present stock is exhausted.

Birmingham, Ala.—The inquiry for 1919 delivery has increased but the booking of orders has not resulted. The making of tentative agreements with the understanding with regular customers that if they shall be on war work in 1919, the iron will doubtless be forthcoming, is about as far as the producers have gone. A large company has issued notices to customers informing them of the necessity of getting on a war basis at once if they wish to be considered in the list of 1919 iron customers.

St. Louis.—Stove foundries are badly in need of pig iron and a considerable tonnage could be disposed of to these plants if the same were available.

Buffalo.—At the present time Government work is taking up practically the output here, but the furnace men hope later on in the second half to have some iron for distribution on old contracts.

Philadelphia.—The producers of pig iron here are not showing any great readiness to take on 1919 business, for the reason that they are not certain that their products will go to the parties to whom they sell. It has been their experience that large quantities of their material have been taken by the Government and sent to parties who have not been customers of theirs in previous times. And at the same time their own trade was neglected.

Cincinnati.—An investigation of the situation affecting the stove makers reveals the fact that very few of them in this territory have sufficient to carry them through the year.

New York.—The general opinion here seems to be that there will not be a pig shortage and at the present time shipments are moving forward satisfactorily so that few complaints from the melters are heard.

The Scrap Metal Reports

The reports on the scrap metal situation from the various industrial centres are in part as follows:

Pittsburgh.—As a result of the recent movement on the part of the authorities to bring all available scrap on the market, a good quantity of this has been found, but the trouble is that much of it is from very remote points. Whether it will be moved or not is a question that has not been settled because the freight rates to bring it to the smelting points would be very high. There is a very decided scarcity of steel, making scrap and the quantity of material is getting past what in ordinary times would be quickly rejected.

Chicago.—More steel scrap should be coming out and that it is not is charged to indifference which should not exist at this time, and a continuance of this attitude may lead to a serious shortage.

St. Louis.—Some of the railroads are offering small lots of scrap from day to day as they accumulate, or as they can be picked up with the short labor supply. Firms that are filled up with military work seem to have very little difficulty in securing smelting material.

Buffalo.—The demand for scrap is particularly heavy and largely exceeds the supply. Numerous inquiries are still unsatisfied. Heavy melting steel also continues in demand at a rate that exceeds the supply.

Cleveland.—It is said that many foundries would be glad to use a larger proportion of scrap in their mixture than at present. They are unable to do so as most of the pig iron that is being supplied is low in silicon.

RUSSIAN ORDERS NOW ON MARKET

Tools Made in States Were Never Shipped to the Eastern Land

Special to CANADIAN MACHINERY.

NEW YORK, Aug. 1.—Makers of guns and shells have placed contracts for machinery in the last week calling for the expenditure of $3,000,000 and similar contracts are pending involving the expenditure of $5,000,000. Manufacturers of aircraft and builders of ships have also placed substantial contracts for machine tools and other machinery. The conversion of many metal working shops in the Central West into war munition plants is resulting in a steady stream of small orders for shop equipment.

The Otis Elevator Co., New York, is about to place orders for 165 machines to be installed in its Yonkers, N.Y., plant for the manufacture of recuperators on gun recoil mechanism. The Himoff Machine Co., Astoria, N.Y., that is making gun mounts, is buying boring and other heavy machinery. The American Car & Foundry Co. is seeking to place an order for 132 24-inch lathes for the turning of shells to be installed in its Cincinnati plant. The same company recently purchased 150 heavy type lathes with the Niles Tool Works Co. Hamilton, Ohio, for the turning of large projectiles for the United States Government.

Big 12-inch Orders

The Maxwell Motor Co. has received an additional contract from the Government for the machining of an enormous quantity of 12-inch shells. The contract price is approximately $40,000,000, making this company's total war business $75,000,000. To expedite the work, the Government will give financial assistance

in building a $4,000,000 addition to the company's plant at Detroit. The Winchester Arms Repeating Co., New Haven, Conn., is buying $500,000 worth of shop equipment to make additional Browning guns for the Government. The New England Westinghouse Co., Springfield, Mass., has bought tools for gun-making and the American Can Co., Edgewater, N.J., has purchased supplementary tools for shell work. American Radiator Co., Bayonne, N.J., is buying additional machinery to increase the output of guns.

These Didn't Go Over

A list of 200 miscellaneous tools which were originally sold to Russian manufacturers has been made out by a local dealer who is now offering the machinery to American manufacturers, as the tools were never shipped and are still carried in New York warehouses. The Brazilian Mission is getting figures from New York dealers on a number of tools for munition work in Brazil.

The Scullin Steel Co., St. Louis, which is building a munition plant for the War Department, has awarded a contract for forge shop machinery to a Cleveland manufacturer.

The Mobile Shipbuilding Co., which has been building wooden ships for the Emergency Fleet Corporation, has received a $12,000,000 contract to build twelve 5,000-ton steel ships; each boat will require 1,670 tons of steel plates and shapes or a total of 20,000 tons and bids are now being taken on the fabrication of the full tonnages of steel, but it is possible that half of the tonnage may be fabricated at Mobile where additional shops and also three more shipways will be constructed. Cranes and machinery for the new plant will be purchased in the near future.

The Bethlehem Shipbuilding Corporation is planning to build two more shipways at its Moore works, Elizabethport, N.J., and also three additional ways at its Sparrows Point, Maryland, plant. Ocean going tugs will be built at Elizabethport and cargo ships at Sparrows Point.

Have Large Orders

The Todd Shipyards Corporation, New York, recently received an additional $15,000.000 contract from the Emergency Fleet Corporation to build twelve 7,500-ton freight boats which will be constructed at Tacoma, Washington. The Government contracts now held by the Todd interests amount to $75,000,000. Several new shipbuilding companies have been incorporated, including the Fabricating Ship Corp., Richmond, Va., with a capital of $1,000.000, and the Connecticut Shipbuilding Corp., New Haven, Conn. The Baltimore Drydocks and Shipbuilding Co. is making plant additions and installing new machinery.

A ¼-inch high-pressure cold water connection to the space below the discharge deck of a pump will prove a quick and effective remedy for vapor bound pumps, also an automatic valve is sometimes connected to this space for exhausting the air or vapor.

THERE'S NO CHANCE FOR STEEL BEING LEFT FOR COMMERCE YET

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Aug. 1.—There has been considerable discussion in steel trade circles the past week of the War Industries Board's general statement, mentioned in this correspondence a week ago, that the war requirements in finished steel for the second half of the year are fully 20,000,000 net tons, while the prospect, based on past performance, is for an output of 16,500,000 tons. The trade does not doubt that there are items which make up a total of 20,000,000 tons or more, but in some quarters there are doubts whether the consuming activities can actually utilize the amount of steel they are calling for, by the end of the current year. The time element, they insist, is precisely as important as the tonnage element. Particular attention is being directed to the fact that while as to the direct war activities the War Industries Board has its records of orders placed and its schedules of orders to be placed, in the case of the commercial industries that are given preference and should be supplied with steel it can have no information of corresponding character, but must depend upon estimates. If the direct war activities, involving the steel the Government itself buys, were to count up 20,000,000 tons, then there would be no use in including the "more essential" commercial activities in the preference list, for that would be an altogether empty honor. These essential commercial industries, including those engaged in the production and preparation of food, in the production of fuel and in the manufacture of clothing, together with the public utilities in general, are all expected to get steel, and more or less according as the supply stretches.

Nothing for Unessentials

One thing has been made quite clear, that there will be little if any steel for the "unessentials" or "less essentials," these terms being used more or less interchangeably. In the first place, the supply will not stretch through the preference list, involving Class C steel, and then into the miscellaneous or unessential demands, such steel being designated as Class D steel, when there is any. In the second place, these consuming industries that are not accorded any preference represent a very small quantity of steel in the aggregate. If only they are to be denied steel there is not much steel saved. Various attempts have been made to compile a list of the "unessentials" but the compilers get nowhere. They start out, with a great flourish, by setting down "pleasure automobiles," not calling them "passenger automobiles" as the producers insist upon doing, but when they come to the next line and the lines following they have to leave them blank. The "preference list" is so comprehensive that there is scarcely anything left. There are items of demand that in normal times would be very important, but the industries involved have almost completely effaced themselves, with the country on a war basis, partly voluntary and partly forced by influences.

The problem of steel distribution, therefore, is to make the steel last down through the preference list, not to have it extend beyond.

Labor Conditions

There being so little that can be done to improve the distribution of steel, attention is directed more to production. It is regarded as decidedly not feasible to build additional plants. That would require a great deal of time and consume labor, materials and transportation facilities. What is of more importance is to obtain maximum production with the plant equipment now available. The problem is largely one of labor supply and labor performance. It is remarkable that the iron and steel industry is in as good shape as it is, when it is recalled that ever since the fore part of 1915 there has been more or less of a "labor scare." It will be recalled that the industry reached an unprecedently low rate of operation towards the close of 1914. Then early in 1915 conditions began to pick up. As demand increased it was seriously contended that there would not be sufficient labor to operate the furnaces and mills at capacity, should demand arise such as to warrant full operation. Some labor had left the country on account of the war in Europe, and immigration was practically stopped, although prior to the war the net increase in population, due to the passenger movement, had been about 60,000 persons a month for two years. Throughout 1916, although operations at capacity had been reached, there were fresh scares. Then when the Government began drafting men to the colors the whole thing had to be gone through with over again.

Nevertheless the condition to-day is that the mills and furnaces are fairly well recruited with labor. There have been various offsets to the drain of labor, and nearly the whole of the offset can be traced to the wonderful work the Government has been doing, through various important activities. It created a Labor Policies Board which should devise means to secure the best performance. As a result of its deliberations the United States Employment Service is now being put into operation throughout the country. Employers engaged in war work and employing 100 men, are not permitted, after August 1, to recruit labor except through this one service. Its methods promise to be drastic, calling upon non-war industries to give up men. Then there are the conciliators of the Department of Labor, who seek to catch cases of industrial unrest, or strikes being fomented, in their incipiency, and many a strike has been averted, or speedily settled, by the work of

(Continued from page 153)

long lines of hose. The fire itself was not of an extraordinary or very serious character from a fire fighting standpoint when the department got there.

Too Many Dead Ends

William Randall, the Toronto superintendent of maintenance and distribution of the Water Works Department submitted certain plans, and in answer to questions put to him it was brought out that in the city there are at the present time no less than 556 of these "dead end" water mains. It is well known that it is impossible from a fire fighting standpoint to secure the same pressure from a dead end main as it is from a main through which there is a constant flow of water. One of the questions in regard to the Spadina Ave. service brought out a remark to this effect, "They practically had no water there at all," and the answer to this was "no" because the water was used by the engines on Bathurst Street and on the lines that were connected up on this hydrant, before it ever could reach that branch.

A New By-law Needed

The deputy fire marshal in conclusion draws attention to this report to a number of things he considers to be very essential in keeping the fire loss down, among other things mentioning smoking on premises, grass fires, old shacks as a fire menace, watchmen's service. He also states that the City of Toronto seems to be lacking in their authority to enforce the requirements of a proper inspection system and should without delay enact a by-law substantially as follows:—

Section 1. It shall be the duty of the Chief of the Fire Department to inspect, or cause to be inspected, all buildings, yards and alleys, as often as may be necessary, but not less than four times a year in the mercantile and manufacturing districts, and twice a year in other districts, for the purpose of ascertaining, and causing to be corrected, any conditions liable to cause fire, or any violation of any by-law affecting the fire hazard. Whenever said Chief or other duly authorized person shall find any buildings especially liable to fire by want of repair, or by reason of dilapidated condition, or defective chimneys, stoves, furnaces, etc., or by reason of any other cause, and when he or they shall find in any building, or upon any premises, dangerous combustible or explosive substances, or accumulations of rubbish, waste paper, empty boxes, or other inflammable material, especially liable to fire, or shall find obstructions to or on fire escapes, stairs, passage-ways, doors, etc., a record shall be made of such inspection, and the Chief of the Fire Department, the Deputy Chief, or the District Chiefs of the Fire Department shall order the aforesaid matters and things repaired, removed or remedied, within a reasonable time specified in said order.

Section 2. The Chief of the Fire Department shall keep a permanent record of all notices given pursuant to the power hereby conferred, and of all inspections and the results of such inspections, together with details of the measures taken to correct any defects or inadequacies so found.

Section 3. The Chief of the Fire Department, Deputy Chief, or District Chiefs, or the Police, or either or both of them, are authorized to enter at all reasonable times, upon any property in order to ascertain whether the provisions of the by-laws are obeyed, and to enforce and carry the same into effect.

Section 4. PENALTY. Every person found guilty of failure or neglect to comply with any of the provisions of this by-law, or with the requirements of any notice or order issued under the authority of this by-law, shall be liable upon summary conviction to a penalty of not less than five dollars ($5.00) nor more than fifty dollars ($50.00).

Section 5. All former by-laws or parts of by-laws inconsistent herewith are hereby repealed.

---

these conciliators, whose work is rarely heard of except locally. Then there is the National War Labor Board, of which former President William H. Taft is one of the two chairmen, which has jurisdiction over cases of particular importance and has been very successful. There are various other activities that have been helpful, particularly in encouraging men to work harder through motives of patriotism in these trying days.

It is beginning to dawn upon the trade that remarkable work has been done, and that labor supply for war industries and industries closely associated with the prosecution of war is not going to be nearly as scarce as would have been imagined considering the amount of industrial activity and the large number of men called into war service.

TRIED THE BONUS SYSTEM TO SECURE PRODUCTION IN MUNITIONS PLANT

Some of the firms in Toronto that are taking on contracts for big shells are doing the first few operations this week, and it will not be long before they have production up to their former standards on other lines of work. One question that is not yet fully settled is the extent to which women will be able to find employment in the shops doing the large calibre work.

"The question of handling the larger shell is going to take a little consideration," remarked the official of one of the plants this morning. "In our case we find that the gravity system that was quite capable of doing the other sizes is not going to handle the big shell satisfactorily. And speaking of handling," he continued, "it is one of the items that simply runs away with money all the time, and it is always a hard factor in overhead. There is about as much non-productive effort in the making of shells for this reason as in anything we have ever handled here. Try as you will it can't be cut very much lower than a good many of the shops have it now, but even yet it runs into a lot of money in the course of a month. Firms want to get production at the maximum figure, and they want to have the machines constantly going, and it all means that the material has to be brought to the machines in a constant supply, and of course that all means that more hands have to be engaged.

The Women Workers

"Our own experience," he continued, "has led us to the belief that we would like to employ women workers here. "When we were pressed for production some time ago we adopted a bonus scale in our shops. We paid the same money to men and women workers on piece work operations, and they worked under the same conditions. We made it a practice as well to give a $2 bonus every time a shop record was made or broken. We did not ask the worker to wait until pay day and have the amount added then, but went on the view that a bird in the hand is worth two in the bush. We would hang up the shop marks on certain operations. Well, the thing was a big success all the way through. As soon as a worker beat out a figure that had been previously high in the shop, an order was given on the pay office, and the bonus of $2 was handed over right away. It was interesting to watch who would get the most of these, men or women. It was our experience that three out of five times the record bonus was paid over to a woman. And as I said before, the men and women were working under exactly the same conditions, and were getting the same rate of pay for their work."

ANOTHER METROPOLITAN DAILY GOES UNDER DEPARTMENT STORE CONTROL

It will be remembered that Stewart Lyon, editor of *The Globe*, Toronto, and the editor of a Winnipeg daily, speaking at the annual meeting of the Canadian Press Association, lamented the fact that editors of the metropolitan daily newspapers had not a free hand. They were hampered by their big advertisers, the owners of departmental stores.

Rodman Wanamaker, of John Wanamaker & Co.'s big departmental store of Philadelphia and New York, who controls the Philadelphia *Press Record* and *North American*, has just been appointed by the will of the late James Gordon Bennett to the control of the New York *Herald* and the New York *Evening Telegram*. Although in control he has not been, nor will he be active personally in newspaper work. It is interesting to observe another big daily newspaper pass under departmental store control.

Your "Uncle Sam" is Not a Bluffer in Any Sense

A Review of His War Activities Will Demonstrate That He Has Gone in for Keeps—In the Past He Has Shown a Tendency to do Things in a Big Way and at Once

By GEO. A. SIMPSON, Sales Manager Steel Co. of Canada.

NOTWITHSTANDING the following, which I clipped from a Canadian paper, your "Uncle Sam" is not a bluffer, and this the Hun will find out to his sorrow:

Washington, July 9.—Publication in Swiss papers of the text of Secretary of War Baker's letter to President Wilson, giving the American troops' movement to Europe by months, caused German authorities to permit its publication in Germany, according to a despatch received from Berne.

The *Koelnische Zeitung* published the latter under the heading "American Bluff," the despatch says, and commented as follows:

"Mr. Baker thinks he will be able to dissipate all doubts about exactitude of his figures with his recitations. It is, however, only the usual American bluff. We know from reliable sources that the figures in question are inordinately exaggerated and in no way correspond to the truth."

And furthermore, he will understand—if he does not already know—that the figures furnished by Secretary of War Baker are not "inordinately exaggerated," but they do correspond to the truth inasmuch as they only represent a small fraction of the force that will be exerted for the cause of humanity before the allied armies reach Berlin.

A Nation of Enthusiasts

The American is an enthusiast, fostering an ambition unbridled by traditionary restraint, for in him commingles the souls of the sturdy Pilgrim Fathers, beset with the cares of existence, conquering nature, felling trees, navigating rivers and fertilizing valleys, and the souls of the Colonists fighting for liberty and independence. He is the child of a country as boundless as the ocean, whose rivers are like rolling lakes, and the lakes like inland seas, the forests, the mountains, the plains, Niagara itself with its world of waters—all owe their magnificence to their immensity; and by transference, not unnatural although fallacious, the Sons of Uncle Sam have modelled their ideas and expressions on the huge scale of their magnificent country, and history proves that anything they have seriously set themselves to do, they have successfully accomplished. But this is to his credit, as nothing great has ever been accomplished without enthusiasm, but he is not a bluffer.

It is true, and I must admit that the words "bluff" and "bluffer" are often applied to American statements and to those who make them. As to why they should be applied to the extent they are, I am at a loss to understand, unless it is through the application of a mental attitude that parallels, in a sense, that of the German toward the English. During the course of the war, I have been asked a number of times by residents of the United States what has England done to incur the hatred of Germany—as no one seems to question that a deep-seated hatred does exist—and to those who first propounded the question, I was at a loss to make an answer. Therefore, I undertook to analyze the subject and I asked myself the question, "What has England done to Germany?" and for the life of me I could not reach any logical conclusion, other than the one I will later outline which justifies in the German mind the Song of Hate, or the toast of "Der Tag" which, in English, is "The Day," meaning the day on which they could pick a fight and thereby show their brutal superiority over a race that they recognized, but would not admit, were their superiors in every commendable particular. I have therefore concluded that their hatred is caused by a mental attitude, born of the fact that the Englishman is a gentleman and as such is recognized by every nation with whom he comes in contact.

Mighty Handy With a Knife

I have before me a mental picture—not altogether imaginary, as I have attended gatherings where different nationalities have sat at the same table—and I can see the German, fat and coarse, with his napkin stuck inside his collar, disposing of his soup with musical accompaniment, using his knife and fork with the same elegance that a plumber would use his tools; in fact, the knife is more to his liking than the fork. I have watched him through the meal, ill at ease, feeling that he was not in harmony with the thought and environment of representative men. I have seen him called on to make a speech, or responding to a toast, rising awkwardly and even where he could speak good English, it sounded to me like someone gargling his throat. In other words, the German is coarse; he is the offspring of a race of butchers, soap-boilers and brewers, and he knows it and shows it. On the other hand, across the table the Englishman, respecting all the good manners recognized in well-ordered society, is called upon to respond to a toast, and with the grace of a Chesterfield, he rises to the occasion and in a few well-selected words, he makes his response. The German knows he is not the equal of the race from which this gentleman sprang, and therefore dismisses the subject by saying under his breath "Englander Schwein."

But the English are not swine, neither is your Uncle Sam a bluffer, yet a state of mind has been created and does exist all over the world, including Canada, which prompts the dismissal of a statement, involving big figures or vast undertakings, made by an American, as "American bluff." To this I have applied the test and I wish to go on record and state in the most emphatic language, that all through the history of the United States I cannot find one instance where statements have been made which, I will admit, sounded like "bluffs," which have not been fulfilled. And I can only conclude that the reason the word "bluff" or "bluffer" has been applied by the people of every nation, who do not realize the stride your Uncle Sam is making, is because they cannot grasp the magnitude of the statements made and they dismiss the subject as "American bluff," while those who do realize it, resent it with the same remark.

Their Declaration of Independence, whereby they severed their allegiance from a crazy German King, sitting on a British Throne, was no bluff; neither was the Emancipation Proclamation, which gave freedom to the slaves, a bluff.

Couldn't Grasp the Idea

As a slight indication of the extent to which the word "bluff" or "bluster" has been applied to the inventive minds and the unbridled energy of the American people and as to how poorly it served as descriptive of their accomplishments, I may state a little incident that I well remember and have many times repeated. I was standing on the railroad platform in Newport, Monmouthshire, awaiting a train to take me to my home. I was then a boy, attending a British Public School. There were a number of other passengers waiting for the same train, among them being the vicar of the parish of Trevethin, a well known and renowned clergyman of the Church of England. He was talking to some farmers, who lived in his district, and the conversation ran about as follows: He told them that he had received a letter from a former member of the church, who had emigrated to America, stating that there had been invented and there was now in use in the United States a machine that while being drawn through the field, would cut the wheat, put it up into sheaves, bind it and drop it, ready for being put into shocks, as it went along.

The conversation was interesting to me as, boylike, I had profound respect for the vicar. I now recall the expression of doubt on the faces of the farmers, and the smile from the vicar who acquiesced with their thoughts, and I can now hear him distinctly stating that he very much doubted that such a machine could be made and applied in general use, with which the farmers, who were at that time cutting their wheat with a sickle, were very much in accord.

When we consider what the sons of Uncle Sam have done for the agricultural world and realize that their first attempts were classed as "bluffs," we can more fully appreciate how ridiculous and uncalled for the expression is. And what applies to the endeavors of Uncle Sam in the production of agricultural implements applies to everything he has seriously undertaken.

Three Days vs. Four Weeks

As a boy I went to sea in an English sailing ship, and I remember very well my first introduction to what I then considered "bluff." We had crossed the Atlantic from England to the West Indies with a cargo of coal and had run down to Pensacola, Florida, for our return cargo of lumber. After we had discharged our ballast, we were towed out into the bay, where our complete cargo of logs had been rafted and was there awaiting us. I remember hearing the stevedore, an Irishman, by the way, by the name of Pendleton, who had lived the best part of his life in the United States, telling his gang that he expected to load the ship in about three days. While I was a very young boy at the time, I shook my head and if I didn't say "bluff," I thought it. Notwithstanding we were loaded and ready to sail within the prescribed time and we arrived in England some ninety days later, where it took the English stevedore and his force some four weeks to unload what the American gang had loaded in a little over three days. No bluff about that.

Some years later I was on the Isthmus of Panama. It was shortly after the collapse of the French company, who had undertaken to build the canal. All the machinery and equipment was lying in idleness and rusting. The Isthmus was reeking at that time with yellow fever and disease and any man who spent much time there took his life in his hand. I was then advised it was impossible to build the Panama Canal, and to drive home this statement, my advisers, pointing to Monkey Hill, which in those days was the famous burying ground of the workers on the Isthmus, said there were more men buried in the cemetery on that hill than there were ties in the Panama railroad. In later years Uncle Sam undertook to "dig the ditch" and the first thing he did was to clean up the Isthmus from ocean to ocean. The greatest sanitary engineers the world knew were put on the job and when this part of the work was done and the Isthmus made fit for a white man to live on, that great organizer, Major Goethals, the canal builder, was ordered by President Roosevelt "to make the dirt fly." As to how well he did this work is now a matter of history; but the facts are the work on the canal. especially any reference to the gigantic dredging operations, were often referred to as Amrican bluff, and when the date set for the completion of the work was mentioned, it usually brought forth the stereotyped reply, "bluff." Nevertheless, the canal was completed and ships passing through it fifteen months prior to the official date set for its completion. Surely this cannot be termed "bluff."

They Came—They Saw

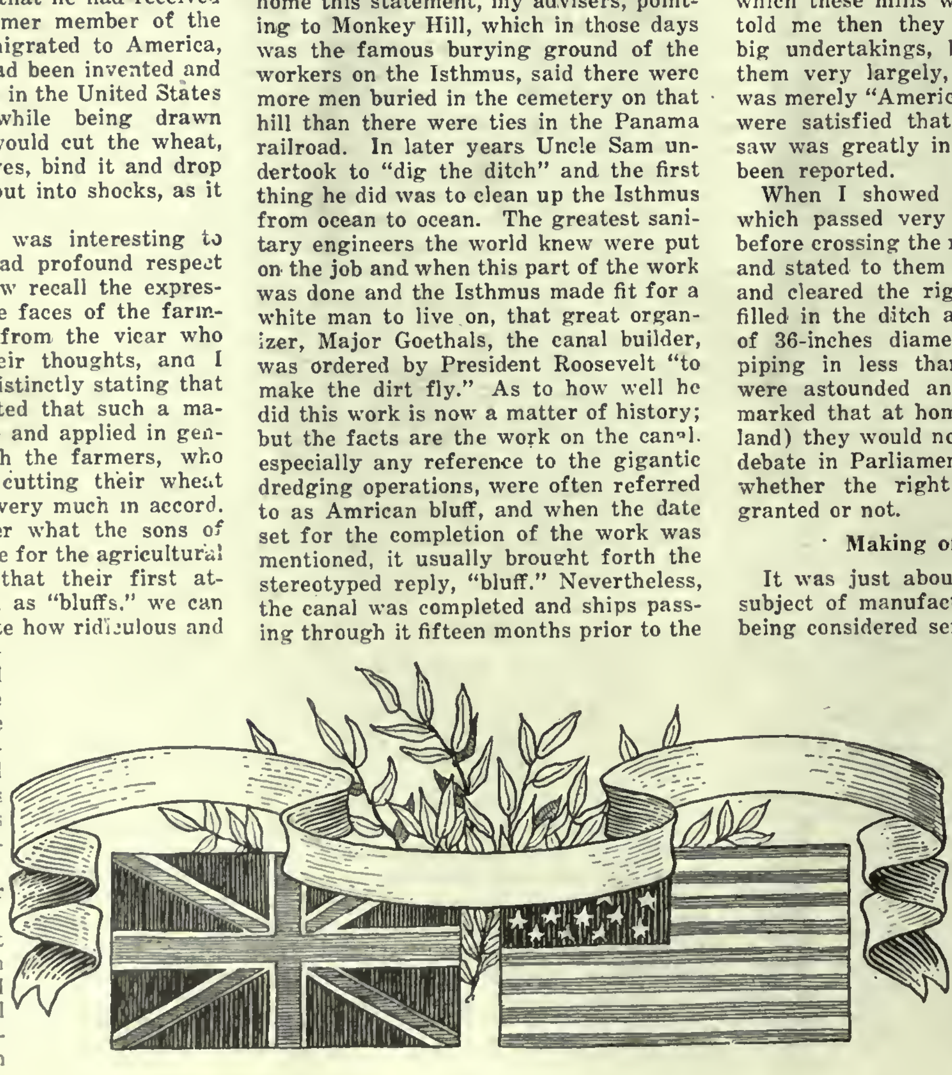
If my memory serves me right, it was in the year 1890 that the British Iron and Steel Institute visited the United States as guests of the American steel manufacturers. At that time I was associated with the T. A. Gillespie Co. We were laying natural gas pipe lines into the city of Pittsburgh and some of our construction records had evidently reached England. When the members of the Institute reached Pittsburgh, it was my pleasure to take charge of a party of six to conduct them through the steel mills at Homestead and, incidentally, outline to them what was being done in connection with the bringing of natural gas into the city. In my party was the president of the Institute, Sir E. Windsor Richards of Middlesboro. Mr. Clement Crowther, of Crowther Bros., Kidderminster, and Mr. Isaac Butler of the Panteg Steel Works. in whose mills I had worked in England, also a number of others, all of whom were descendants of families long connected with the iron and steel industry.

I recall now the statements they made on going through the mills and their utter amazement at what they termed "the gigantic buildings" and what in their minds was the enormous output, which these mills were producing. They told me then they had heard of these big undertakings, but had discounted them very largely, as they thought it was merely "American bluster," but they were satisfied that what they actually saw was greatly in excess of what had been reported.

When I showed them the gas lines, which passed very close to Homestead before crossing the river into Pittsburgh, and stated to them that we had secured and cleared the right of way, dug and filled in the ditch and laid eleven miles of 36-inches diameter continuous steel piping in less than five months, they were astounded and Mr. Crowther remarked that at home (meaning in England) they would not have concluded the debate in Parliament in that time as to whether the right of way should be granted or not.

Making of Tin Plate

It was just about this time that the subject of manufacturing tin plate was being considered seriously in the United States, and I so advised these gentlemen, and while they were willing to admit that all the statements that had been made in reference to pig iron and steel had been more than fulfilled, nevertheless it was not possible in their mind for any one to take Great Britain's place in the production of tin plate. They were



inclined to jokingly infer that my statements in connection with this industry bore a little resemblance to "bluff." I may state that to-day the United States leads the world in the production of tin plate, likewise pig iron and iron and steel.

There was no question as to the effect of what they saw on the minds of the members of the British Iron and Steel Institute, or as to the benefits obtained through their visit, as they all returned singing the praises of your Uncle Sam and voted unanimously that he was not a "bluffer." And on the Americans, who had come into contact and associated with this magnificent body of representative Englishmen, the impression was indelibly stamped that they were gentlemen in every sense of the word.

I could go on indefinitely reciting statements that were regarded as "bluff," but which were fulfilled to the letter. While the Alfonsos and Isabellas sneered at what they termed "American bluff," your Uncle Sam was not bluffing when he lifted the heel of Spanish tyrrany from the neck of the Cuban and cleaned up the Island of Cuba and dredged the harbor of Havana and thereby got rid of the filth of centuries, which made this beautiful island a hot bed of bubonic plague and yellow fever. As a result to-day there is no more beautiful spot on the Western hemisphere than the Island of Cuba and the city of Havana. It is true, while doing his work, he lost by death, through yellow fever, an eminent sanitary engineer, but he completed the job and made good his wildest statements. And what is more—he paid the bill and to-day Cuba is proud to be recognized as a protege of Uncle Sam.

The Boxer Incident

And while I am referring to paying bills, I might state that during the Boxer Rebellion in China, when the six big nations of the world undertook to quell the disturbance, they all went in with the understanding that China would pay full indemnity for every expense incurred in the undertaking. After the work had been accomplished and the civilized nations had withdrawn, which, by the way, does not include Germany, as she stuck and took possession of Tsing Tau Peninsula and refused to be dispossessed, maintaining that she was holding this possession as payment for the expense she had been put to, they rendered their bills—which ran into enormous figures—and all of them are being paid with the exception of the one rendered by your Uncle Sam, which he returned to China marked "paid in full," with thanks for the privilege of being given an opportunity to render such a service to humanity. Surely this is not "American bluff."

The feeding of Belgium in the early part of this war was no bluff; neither is the feeding of the Allied armies today, or that part that your Uncle Sam has played in this great war from the beginning. Referring to the feeding of the armies to-day, I am reading from an address made by Sir William A. M. Goode, an officer of the British Food

Ministry, before the Consumers' Council, in which he gave striking figures, showing how the people of the United States by self-imposed food restrictions have aided greatly in maintaining the food supply of the armies in the field. Sir William said:

"From July, 1917, to April, 1918, the United States exported to the Allies 80,000,000 bushels of wheat products. It was calculated by Herbert Hoover, United States Food Administrator, that fifty million of this represented the voluntary sacrifice of the American people. American exports of pork products to the Allies in March, 1918, were 308,000,000 pounds. This was accomplished by porkless days and ceaseless hog production in the United States. In January, Sir William continued, the Allies asked Mr. Hoover for seventy million pounds of frozen beef monthly for three months. In March 86,000,000 pounds of frozen beef were shipped. This was due almost wholly to meatless days in the United States."

Had this statement been made by an American, it would, no doubt, have been dismissed as "bluff."

I would like to furnish some more figures and I would if space permitted, but suffice to say it required more than bluff to supply Great Britain and France with over 1,500,000 horses and mules; millions of tons of steel and shell forgings, hundreds of thousands of tons of barbed wire, and tens of millions of completed shells, machine guns, revolvers, together with hundreds of millions of pounds of powder and cordite to assist in delivering these shells into the ranks of the Germans by way of British guns. Add to this the enormous quantity of machine tools and equipment that was shipped to England and France, which enabled them to speed up and take care of their own requirements. Add to these transports, trench diggers, tanks, automobiles, medical supplies, clothing, shoes—in fact, mountains of supplies—that were absolutely necessary for the very existence of the allied armies in the field. We grant he was paid for all this, but that he was entitled to. What I wish to bring to your notice is the magnitude of this undertaking and the manner in which it was carried out, and many times during the early period of the war I heard statements made by these American producers, who had undertaken this magnificent work, referred to as "American bluff."

Some 1918 Accomplishments

The building of the Liberty Mill at Homestead in six months for the rolling of ship plates, the construction of a one-hundred-million-dollar ordnance plant on Neville Island in the Ohio River, near Pittsburgh; the building of shipyards from ocean to ocean and the launching of ninety-four ships on the Fourth of July are merely incidents in the vast war programme mapped out by Uncle Sam. Yet any one of these undertakings is stupendous. They form parts of the American war machine, and you can take it from me that when this force gets properly started, there is no power on earth can stop it. It is no bluff; it is Uncle Sam's contribution to a righteous cause, and shoulder to shoulder with his Allies, he will drive it across the Rhine.

While I know from experience that the great majority of Canadians fully realize and appreciate that Uncle Sam is a good neighbor and that he is not a bluffer, I also know there are small cliques of narrow-minded individuals in Canada, who are earning their Iron Crosses and doing good work for the Kaiser by sneeringly applying to all things American the word "bluff" and thereby attempting to discount their most sincere efforts. Such individuals should, in my judgment, be reported to the proper authorities, where they would be given an opportunity to prove whether their remarks were merely expressions of their personal opinions, or whether they were paid for with German gold.

The Wrong Viewpoint

An incident I shall ever remember and long regret happened on a train some months ago. I was sitting in the parlor-car. We were leaving Hamilton, going to Toronto with a friend, and across from us sat the president of a large Canadian manufacturing company. He was reading a Buffalo paper and evidently some of the headlines did not please him. Handing ths paper to me, he pointed to an article and remarked: "What do you think of that American bluff?" The article referred to a loan of a few billions to the Allies and incidentally spoke of helping to deliver the punch that would knock out the Hun. I saw nothing objectionable in the article and called his attention to the fact that he was reading an American newspaper, and I further stated that, in my judgment, the help we would get from Uncle Sam was necessary and that had the United States not entered the struggle to take the place of recreant Russia, Germany might have forced a peace of her own devising upon the Allies, to which he objected, stating definitely that he would rather see the Allies beaten than have that bluffer take any of the credit. The cruelty of this remark was sufficiently effective to stun both of us, to whom it was directed, and while we felt like beating him up, or handing him over to the police, we ignored him; but not without taking his mental measure and concluding he was either crazy or profoundly pro-German, preferably the former.

I fully realize that Canada could exist without her neighbor; but it would not be a very modern existence, neither would it be a very progressive one. But I also realize that we can get along much better with the United States than without. We are absolutely dependent on Uncle Sam for a whole lot of our comforts. Take hard coal for one—yet notwithstanding there was a great shortage last year due to the war, it is a fact, the homes of Canada were more comfortably heated than the homes in the United States, and I know that the orders from Washington relating to the distribution of certain materials were positive, as a prominent official there told me that Canada was being treated as one of the States. This spirit prevails and governs the actions of Uncle Sam in all his dealings with Canada.

Canadians should not forget that Anglo-Americans wrote the Declaration of Independence and the Constitution of the United States; they produced George Washington. Abraham Lincoln and Woodrow Wilson; they were the makers of trails and the givers of laws; they opened up the American wilderness; they drove the roads and bridged the streams and the roads they drove were straight and the laws they gave were broad and kind, and to-day the eyes of the world are looking west for they know that your Uncle Sam is not a bluffer. They are beginning to realize what America stands for.

The Spirit of America

My message is prompted by the most sincere thought and best wishes, because I want Canadians especially to know what the spirit of America is. I want to get into their very souls the passion and love for the sons of Uncle Sam that the sons of Uncle Sam have for them. I want them to understand that their heart is as great as the nation over which their emblem of liberty flies, and what is more, it beats true and in sympathy with all that can be termed human fellowship. It is consecrated to the highest ideals of humanity in its noblest form. The spirit of America is liberty, but it does not invade the rights of others, for it well knows that to enjoy liberty, it must extend it to others. It pleads for the rights of men to think, to reason, to investigate to the end, that the future may be enriched with the thoughts of honest men. It implores every human being to be a soldier in the army of progress, and it extends to him every right it claims for itself, believing that when all men give to all others all the rights they claim for themselves, the world will be civilized. Uncle Sam has had his difficulties, but they have stimulated, rather than stifled, his energy and the spirit of America, born of liberty, justice and truth, has surmounted a greater variety and combination of obstacles than I believe ever fell to the share of any one people in the same space of time, and to-day it is returning to the world the fruits of the belief that the universe was planned for good and the blessings of Creation were intended for the admiration and benefit of all mankind.

STORAGE OF COAL

Some notes on the storage of coal with reference to the prevention of spontaneous combustion were given by Mr. John H. Anderson before the Institute of Marine Engineers, London.

The author said that his remarks were based in particular on experience gained with a heap containing just over 16,000 tons. The heap consisted entirely of small bituminous coal, of several kinds, washed and otherwise, some being of a character supposed to be dangerous for storing. Under these conditions extra care was exercised. Temperature readings were taken at 14 different places nearly every day, and occasionally also at the vent pipes, of which there were 50. Further, to find the hottest part, readings were taken at every foot from top to bottom at certain places. Previous experience indicated that the warmest place was between 6 ft. and 8ft. from the surface; hence 7ft. was established as a standard depth for temperature records. The temperature tubes were ¾ in. or 1 in. gas tubing, driven in from the top to the bottom of the coal and long enough to project 2 ft. or 3 ft. above it. In most cases the vent pipes were old scrap tubes about 8 ft. long and 3 in. or 4 in. in diameter, and were driven down to the 7 ft. mark, their ends being flattened, chisel-shape, to facilitate driving.

By taking periodical readings of the temperature of the pile and comparing them with previous readings ample warning was obtained to prevent a fire. If a readying of 90° F., which was adopted as a warning temperature, was obtained at any place four other temperature tubes were driven down north, south, east and west about 10 ft. from the warm tube. The tube which gave the highest reading next day was then made the centre, and other pipes put down in its direction, the idea being to locate the source of heating. When the warmest place was found an additional vent pipe would be put in there, and this generally arrested the rise of temperature. If, however, it did not, a trench was dug a foot deep on each occasion—that is if the readings remained at, say, 100° for three days the trench would be 3 ft. deep. In fact a temperature of 100° was never reached, but on four occasions, when 95° was recorded at a point where the coal was deposited to a depth of 16 ft., a trench was dug. Probably, however, this trenching would have been unnecessary had additional vent pipes been inserted. If a fire occurs, although plenty of water should be available to quench it, it is better to dig all round it, and if possible remove the hot coal.

In general the depth of the heap should not exceed 12 ft. to 14 ft. for small graded coals, or 9 ft. to 12 ft. for unwashed mixed coals. As regards slacks, a good deal depends on the composition. The author allowed two heaps of this material 10 ft. deep to rise to 120° before moving them, and they gave considerable trouble; even when they were reduced to 6 ft. there was a tendency for them to increase in temperature. Anything, such as pieces of wood, pit props, rags, waste, shavings, and straw, that ignites at a lower temperature than the fuel should be kept out of the heap. As a rule the greatest danger is up to about three months from the time the coal is taken out of the pit.

APPROVAL VS. CRITICISM

"I am a believer in the fact that men do their greatest accomplishments by proper encouragement, not by criticism. I have yet to see the man, however great and exalted his situation, who is not susceptible to the approval of his fellow-man. I have yet failed to see the man, who is worth calling a man, who does not put forth his best efforts under the approval of his fellow-men. And the severest criticism that can come to any man is not to find fault with him, but not to notice him at all.—Schwab.

Changed Hands.—John T. Hepburn, Limited, of Toronto, has taken over the plant of the Martin Pump & Machine Company, 47 Dawes Avenue. The intention is to manufacture Hepburn special shell lathes for the present, and later a complete line of steam and water pumps.

New Plant of the Fred Thompson Co., Montreal

Growth and Development of the Electrical Business and the Increasing Demand for All Sorts of Equipment Has Brought With it the Necessity for Greater Buildings to Handle the Work

FEW activities of the present have shown such remarkable developments as that of electrical industry. Much of this expansion has resulted through the agitation for greater fuel conservation, so that many firms in the electrical branches have required additional plant facilities to handle the increasing business. The Montreal firm of Fred Thompson Company Limited, one of the oldest and best known in the electrical industry throughout the Dominion, has recently erected and occupied a new three-story factory on Genevieve St., a short distance from their previous location on Craig Street, where they had been carrying on business for the past nineteen years. This firm had its origin in 1894, being first founded by Fred Thompson, a pioneer in the electrical business. Mr. Thompson came to Montreal in 1882 and held the position of chief electrician with the old "Royal" Electric Company, for nearly twelve years. The initial office of the present firm was located in a small room of the old Temple Building on St. James St. Under the capable leadership of its present head the company had a steady expansion, the culmination being the recently well equipped and modern establishment.

NEW PLANT OF FRED THOMPSON CO., MONTREAL. SECOND FLOOR WITH OFFICES IN THE REAR.

A Well Built Place

The new three-storey and basement building has a total floor space of over 30,000 square feet, and is of brick and concrete fireproof mill construction, well lighted from three sides with metal sash windows. Fire doors are provided on the floor level of each stairway, each door fitted with fusible links. The various floors are arranged to accommodate the different departments to the best advantage, facilities being provided to handle the work rapidly and economically. The top floor is fitted out as a drafting and designing room, storeroom, pattern room, transformer department, and the coil making department. The front section of the second floor is reserved for the general and private offices, while the back portion is equipped for repairs and testing of the smaller electrical equipment; here all general repairs, winding, assembling and testing are carried on. A portion of this floor is set aside for impregnating and baking of the parts. Located on the concrete floors are the dipping and impregnating tanks and the electrically heated baking ovens, with an overhead travelling crane that handles all motor parts, heavy coils, etc., between the tanks and the ovens. This department with the switchboards and accessories is amply provided with the necessary facilities for testing at all voltages and also at any of the frequencies desired on alternating current, and also at any of the required voltages on direct current equipment.

NEW PLANT OF FRED THOMPSON CO., MONTREAL. GROUND FLOOR WITH SECTION OF MACHINE SHOP TO RIGHT.

The receiving and shipping room is located on the ground floor, also the general show room, conveniently arranged for the display o fall new and ready-for-sale second-hand machinery. The rear portion of this floor is reserved for the machine shop, and a general repairing and assembling department for the heavier equipment. In the basement are located the presses and machines for punching and cutting the discs for the stators and rotors, and also for the induction motors manufactured by the firm. Storage space is also provided for second-hand machinery, motor castings, pulleys, heavy hardware, etc.; also the heating apparatus.

Each floor is provided with overhead runways for portable chain blocks to facilitate the handling of the work. A Turnbull freight elevator operates from the basement to the top floor to transfer material from one department to another. Accommodation in the way of wash rooms and toilets is provided for the workmen.

This company makes a specialty of electrical repairs of every description—from fan motors to the largest electrical units now in use. They also manufacture induction motors up to 25 h.p. capacity and expect in the near future to enlarge in this connection. They design and construct electrical equipment of all kinds, transformers, magnetic apparatus, coils, etc., for special purposes. They buy, sell and exchange new and second-hand electric motors, generators, etc., guaranteeing all repairs that go through their factory. The new factory was designed and constructed by Jas. H. Hunter of Montreal. The present officers of the company which was incorporated as a joint stock company in 1913, are: Fred Thompson, president and general manager; Clarence Thompson, vice-president and secretary-treasurer; H. A. McPhee, superintendent; A. Walker, and J. B. Lacroix, electrical engineers.

NOTHING LIKE SYSTEM

"Don't tell me you can't remember things!" said Tom to John. "Memory is all a matter of system. Now, in what year was the battle of Agincourt fought?"

John pleaded that his memory failed him on that interesting historical fact.

"Exactly!" replied Tom. Now, how many days are there in a week?"

"Seven," came the answer.

"Very well. Twice seven is fourteen. Multiply by a hundred—fourteen hundred. Number of days in June, thirty. Half of thirty, fifteen. Fifteen and fourteen hundred?"

"Fourteen hundred and fifteen," murmured John.

"Right! That's the year the battle was fought. System, my boy, That's what does it—System."

AN UNSOPHISTICATED WITNESS

On a recent public occasion Chas. M. Schwab had occasion to refer to the coaching of witnesses and told of a foreman who worked for him once, who had come to Washington to appear before a committee that was investigating something. "I thought I had him pretty well coached; I thought I had him well trained what to say. I sat in the corner and watched him and presently found that he was straying a little from the training, and I shook my head at him, and in old-fashioned mill style he looked at me and said, "Well, damn it, Charlie, that's what you told me to say."

DESCRIPTION OF LIBERTY MOTOR AS AUTHORIZED BY WAR DEPARTMENT

The War Department authorizes the following statement :

The designs of the parts of the Liberty engine were based on the following:

Cylinders—The designers of the cylinders for the Liberty engine followed the practice used in the German Mercedes, English Rolls-Royce, French Lorraine-Dietrich, and Italian Isotta Fraschini before the war and during the war. The cylinders are made of steel inner shells surrounded by pressed-steel water jackets. The Packard Company by long experiment had developed a method of applying these steel water jackets.

The valve cages are drop forgings welded into the cylinder head. The principal departure from European practice is in the location of the holding-down flange, which is several inches above the mouth of the cylinder, and the unique method of manufacture evolved by the Ford Company. The output is now approximately 1,700 cylinder forgings per day.

Camshaft and Valve Mechanism Above Cylinder Heads—The design of the above is based on the Mercedes, but was improved for automatic lubrication without wasting oil by the Packard Motor Car Company.

Camshaft Drive—The camshaft drive was copied almost entirely from the Hall-Scott motor; in fact several of the gears used in the first sample engines were supplied by the Hall-Scott Motor Car Company. This type of drive is used by Mercedes, Hispano-Suiza, and others.

Angle Between Cylinders—In the Liberty the included angle between the cylinders is 45 degrees; in all other existing 12-cylinder engines it is 60 degrees. This feature is new with the Liberty engine, and was adopted for the purpose of bringing each row of cylinders nearer the vertical and closer together, so as to save width and head resistance. By the narrow angle greater strength is given to the crankcase and vibration is reduced.

Electric Generator and Ignition—A Delco ignition system is used. It was especially designed for the Liberty engine to save weight and to meet the special conditions due to firing 12 cylinders with an included angle of 45 degrees.

Pistons—The pistons of the Liberty engine are of Hall-Scott design.

Connecting Rods—Forked or straddle-type connecting rods, first used on the French DeDion car and the Cadillac motor car in this country, are used.

Crankshaft—Crankshaft design followed the standard 12-cylinder practice, except as to oiling. Crankcase follows standard practice. The 45-degree angle and the flange location on the cylinders made possible a very strong box section.

Lubrication—The first system of lubrication followed the German practice of using one pump to keep the crankcase empty, delivering into an outside reservoir, and another pump to force oil under pressure to the main crankshaft bearings. This lubrication system also followed the German practice in allowing the overflow in the main bearings to travel out the face of the crank cheeks to a scupper which collected this excess for crankpin lubrication. This is very economical in the use of oil and is still the German standard practice.

The present system is similar to the first practice, except that the oil, while under pressure, is not only fed to main bearings but through holes inside the crank cheeks to crankpins, instead of feeding these crankpins through scuppers. The difference between the two oiling systems consists of carrying oil for the crankpins through a hole inside the crank cheek instead of up the outside face of the crank cheek.

Propeller Hub—The Hall-Scott propeller-hub design was adapted to the power of the Liberty engine.

Water Pump—The Packard type of water pump was adapted to the Liberty.

Carburetor—A carburetor was developed by the Zenith Company for the Liberty Engine.

Bore and Stroke—The bore and stroke of the Liberty engine is 5 by 7 inches, the same as the Hall-Scott A-5 and A-7 engines, and as in the Hall-Scott 12-cylinder engine.

Remarks—The idea of developing Liberty engines of 4, 6, 8 and 12 cylinders with the above characteristics was first thought of about May 25, 1917. The idea was developed in conference with representatives of the British and French missions, May 28 to June 1, and was submitted in the form of sketches at a joint meeting of the Aircraft (Production) Board and the Joint Army and Navy Technical Board, June 4. The first sample was an 8-cylinder model, delivered to the Bureau of Standards, July 3, 1917. The 8-cylinder model, however, was never put into production, as advices from France indicated that demands for increased power should make the 8-cylinder model obsolete before it could be produced.

Work was then concentrated on the 12-cylinder engine, and one of the experimental engines passed the 50-hour test August 25, 1917.

After the preliminary drawings were made, engineers from the leading engine builders were brought to the Bureau of Standards, where they inspected the new designs and made suggestions, most of which were incorporated in the final design. At the same time expert production men were making suggestions that would facilitate production.

The Liberty 12-cylinder engine passed the 50-hour test, showing, as the official report of August 25, 1917, records, "that the fundamental construction is such that very satisfactory service with a long life and high order of efficiency will be given by this power plant, and that the design has passed from the experimental stage into the field of proven engines."

How the Vickers Co. Have Turned Out War Material

Makers of a Great Variety of War Material—Secrecy of Methods in the Old Land is Giving Way to Well Placed and Directed Publicity by the Authorities

IN the earlier part of the war considerable secrecy was insisted on by the various governments respecting the activity of the numerous industries contributing to the war effort. As developments proceeded apace it latterly became apparent that much benefit in the way of moral support and stimulation of output would result from judicious publicity regarding some of the spectacular and novel features of the situation.

One of the most pleasing features has been the constant frequency with which the King and Queen have visited numerous factories, mills, mines and explosives works throughout England and Scotland, resulting indirectly in much public interest in the plants visited. As a result of such events a number of photographs were recently published by "Engineering," of London, Eng., showing some departments of national and privately-owned establishments which had been visited by their Majesties.

Howitzer Production

The well-known Vickers' concern

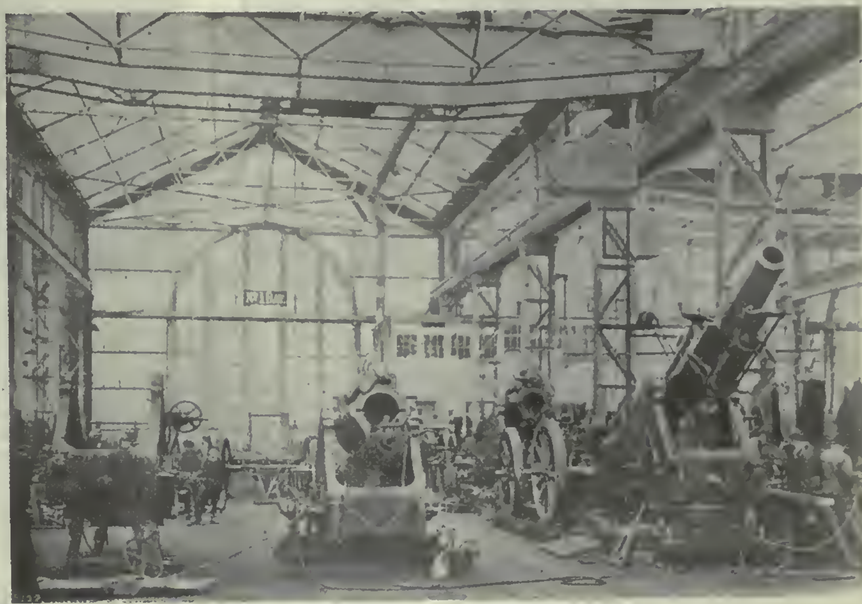


FIG. 1—ONE OF THE FIFTEEN BAYS AT THE NEW HOWITZER SHOP OF THE VICKERS' COMPANY IN ENGLAND.

FIG. 5—VIEW OF ONE OF EIGHT BAYS OF A LARGE SHELL SHOP FIVE MONTHS AFTER THE SITE WAS OCCUPIED.

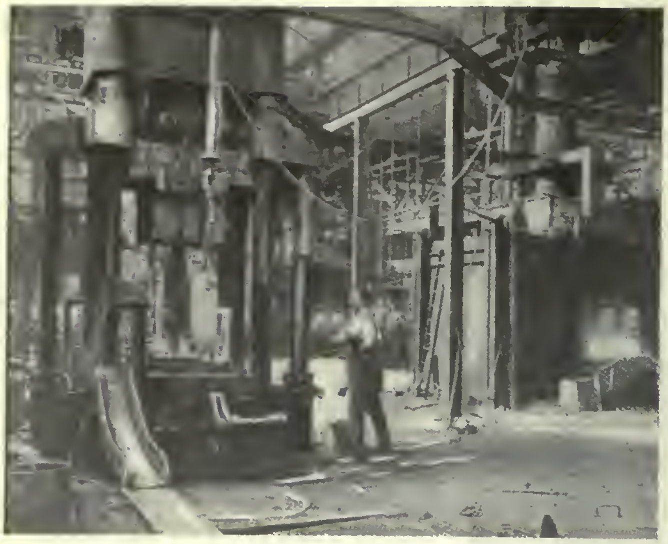

FIG. 6—FORGING 9.2 IN. SHELLS IN A BRITISH NATIONAL PROJECTILE FACTORY.

FIG. 7—WOMEN PRESSING BANDS ON 9.2 IN. SHELLS IN A BRITISH NATIONAL PROJECTILE FACTORY.

occupies a prominent place in the munitions world and a view of an entirely new howitzer shop at one of their establishments is shown in Fig. 1, while representative howitzers built there are shown in Figs. 2, and 4.

The building of this howitzer shop was commenced in August, 1915, the site being a private wooded park, and the building, which is admirably designed and completed in a thoroughly permanent character, has an area of 172,000 sq. ft., made up of 15 bays, all of uniform dimensions and equipped with specially designed plant and machines for the manufacture of the various units of howitzers.

When construction was started the firm guaranteed a certain monthly output in August, 1916, but the building was so quickly erected and the plant installed that the original output was exceeded within nine months of the site being taken over by the builders. Since then a considerable part of the field and howitzer equipment of the British army has originated in this shop.

Much of the important work, even in this department, is carried out by women machine workers under the supervision of male trained experts, who by this broad-minded action are performing a loyal service to their country. A certain small proportion of the men, however, take a narrow view on the question of labor dilution and endeavor to support their views by aggressive action.

It is not permitted to enter into detail regarding the design of the weapons produced, but the views shown are largely self-explanatory.

A Prominent Plant

Illustration Fig. 6 shows the interior of one of eight bays of a large shell shop which was erected by the Vickers' firm immediately after the outbreak of war. Commencing the foundation work in October, 1914, the plant had a considerable output of large-size shell in the spring of 1915. Fig. 6 was taken five months after the site was occupied.

The eight bays are each 60 ft. wide and from 400 to 475 ft. in length, and include a gallery 270 ft. long where the smaller shells are manufactured entirely by female labor.

A feature of the work done at this plant was the remarkable variety of shells turned out. This statement is not made in disparagement of highly specialized plants, but was due to the fact that the company, having a completely experienced staff prior to the war, was able to give, for the benefit of new-coming firms, the nucleus of new shell-manufacturing staffs, and in this way their indirect services were of as much influence as the direct production of shells.

National Projectile Factories

Figs. 6 and 7 are two views in a National projectile factory. The plant illustrated was commenced in September, 1915, and delivered the first shell in the following March. There are 20 bays of similar construction ranging in length from 600 ft. to 925 ft., and in width from 50 ft. to 38 ft. The total area of the plant is 37¼ acres, of which 12¾ acres are covered by buildings.

A self-contained power plant had to be provided of 6,000 horse power to provide hydraulic power for the forging presses, electricity for light and power, and compressed air for the pneumatic tools. Owing to the predominance of women workers every machine tool is fitted with a crane to reduce fatigue of operation to the lowest point. A very complete system of transportation is installed, while the trackage of industrial railway throughout the shops exceeds three miles.

National shell-filling factories followed as a natural sequence and the Vickers. Co. participated in this work largely. The plant referred to has a total area of 400 acres, the buildings alone covering over 1,000,000 sq. ft. Within the works are 11 miles of railway, while 3½ miles of timber runways were constructed to obviate the necessity of the workers going across open ground and running the risk of entering buildings with grit on their boots.

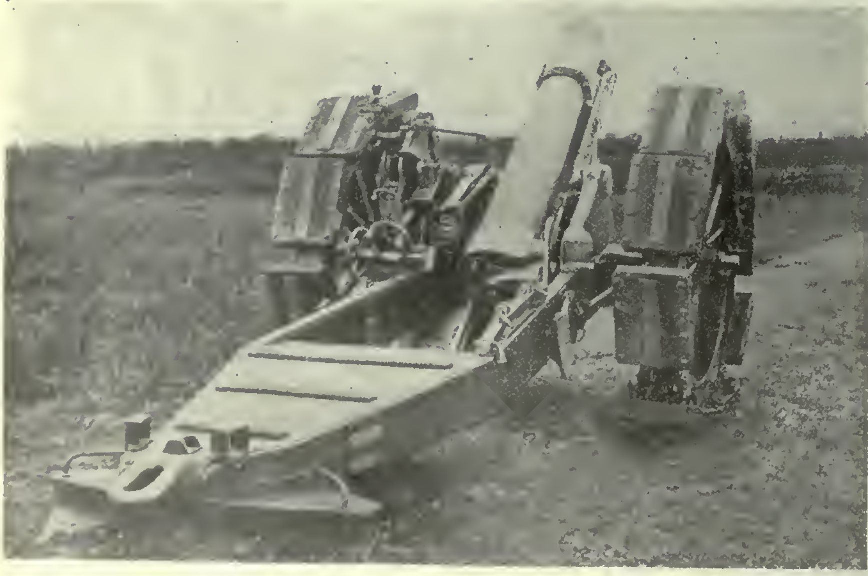

FIG. 3—6 IN. BRITISH HOWITZER.

Germans Are Ignorant of What Is Happening

Captain Len Morrison Spent Two Years in a German Prison Camp —Says Civilian Population is Suffering From Lack of Necessities —In France Early in 1915

THE following details of the treatment accorded to prisoners in Germany given to CANADIAN MACHINERY by Captain Len Morrison of Toronto, who was repatriated and arrived home last week, does not improve one's appreciation of German kultur. Captain Morrison as an officer received much better treatment than is accorded hundreds of thousands of other prisoners, and while he did not see how these other men were used he heard many accounts of almost unbelievable cruelty. Captain Morrison is a son of James Morrison of the Jas. Morrison Brass Mfg. Co., Ltd., of Toronto.

He was in England taking part in the shooting at Bisley when war was declared and at once made application to enlist for active service. He was advised by the British authorities to return to Canada at once and join his own regiment, the 10th Royal Grenadiers. He at once cabled his services to Col. Brock, the O. C. of the Grenadiers, and soon after arriving in Canada was sent to Valcartier and from there to England.

Hit at Ypres

He was sent to France early in February of 1915 and at the second battle of Ypres, in which the Canadians lost so heavily, was sent up to the firing line in charge of reinforcements for the 13th Battalion. Owing to conditions he was unable to connect with that unit and while battling with the Germans in a trench into which he had ordered his men, was struck by a machine gun bullet in the right leg just above the knee. A compound fracture resulted and the bullet passed on and injured the left leg also.

While Captain Morrison was having his injury dressed by a soldier the man looked up and saw the Germans coming and at once took to his heels. Just about this time the British artillery opened a heavy fire on the advancing Germans. Captain Morrison was caught in this and was frequently covered by the dirt thrown up when shells burst, but escaped serious injury. He dragged himself along, slowly and painfully, until he found a more sheltered place and then, after fixing up his wounds as best he could, waited. It was 36 hours before he was picked up by a party of Germans.

CAPTAIN LEN MORRISON

Saxons All Right

"I was fortunate at first in falling into the hands of Saxons," said Captain Morrison. "The Bavarian troops are very rough and the Prussians even worse. When I saw the party coming I just shut my eyes and waited for the worst, not knowing into whose hands I was going to fall. The men, although they were in a hurry, treated me kindly enough and carried me to a sheltered spot and after putting a rubber sheet under me, put another one over me and a greatcoat on top of that and left me. It was a good thing they had fixed me up as it commenced to rain and came down pretty heavy nearly all night. Next morning one of the Saxons, a young private, gave me his own ration of coffee and bread. I gave him some cigarettes. Soon after a medical officer came and my wounds were attended to and I was sent to a rail head. Here I was placed in charge of a young officer who could speak excellent English. He told me he had been in New York when the war started, and when I told him I was from Toronto he said he had been there.

Gloated Over It

"Soon after the officer had left me and while I was waiting to be lifted on the train, I had my first experience of German kultur. I was quite helpless as far as my legs were concerned and a German soldier who had been watching me came over and kicked my leg as hard as he could. Fortunately he kicked the left leg, which was not fractured. In order to deceive him I made

FIG. 2—9.2 IN. HOWITZER ON SIEGE MOUNTING.

FIG. 4—9.2 IN. FIELD HOWITZER.

a face as though he had hurt me badly and he went away in great glee."

Captain Morrison was taken to the hospital at Ghent, where he spent six months and was well treated. As soon as he was able to get around he was transferred to the Craefeld Prison Camp, in Westphalia. This is only eighteen miles from the Holland border and as attempts to escape are made almost every night the discipline is severe. There were 1,200 prisoners there when Captain Morrison arrived, of whom 300 were British officers. One of the first things he noticed was the manner in which the German military authorities keep the people in the dark as to what is happening in the outside world. The prisoners were permitted to have the German newspapers and translations of the news was made by officers who were able to read German. The news was obviously all carefully gone through before it was allowed to be published and everything that was in the nature of a German success was made the most of while reverses of any kind were not mentioned.

People in the Dark

"The whole policy," said Captain Morrison, "is to keep the people in ignorance of what is happening They were fed up on tales of the prodigious successes of the German armies."

One of the plans of the military authorities is to keep the prisoners moving. Captain Morrison was not kept at any of the prison camps for any length of time. The reason probably is that when the men become familiar with their surroundings they have a better chance to escape. The worst prison camps in Germany are in Hanover, and it was to one of these that Captain Morrison was soon sent.

"We were given such short notice that we were to be moved," he said, "that many had to leave without even a chance to get together their belongings. Many of the officers under the impression that they might stay at Craefeld for some little time had from their own private funds fixed up their quarters by having them repapered and additional furniture moved in. They were rather rudely surprised at being given no chance to even get things they needed. We were simply rounded up into parties and told we were to be moved and had to wait until the authorities were ready to move us, which wasn't long. From Craefeld I was taken to Schwarmstedt, and after a couple of weeks there was taken to Holzminden. Both these camps are in Hanover. The sand which surrounds the quarters is full of fleas and the sanitary arrangements were very bad. The beds were full of vermin and the heat was something terrific. While we were allowed to make protests regarding conditions absolutely no notice was taken of them. We had to do our own washing and cooking with the scantiest of appliances. Many of the men suffered greatly and there was a great deal of sickness. One of the common things which results from being kept in a German prison camp very long is loss of memory. Up to this time we had been able to get a fair variety of food, but it was not long before conditions in Germany began to be felt in our camps. At Holzminden each morning we were given coffee made out of acorns and unpalatable stuff. At noon and in the evening we each got a bowl of soup which was made from some kind of weeds and was anything but inviting. These camps are known as strafe or punishment camps and they certainly are well named."

Some More Kultur

At Holzminden the camp commandant was Captain Neimyer and his one mission in life, according to Captain Morrison is to go around and make things miserable for the prisoners.

"Nothing would satisfy him," said Captain Morrison; "his one idea was to roam around looking for trouble. The heat was terrific but he decided that it would be most unwise to allow the windows to be open at nights. The mattresses on which we had to sleep were very dirty, so between Captain Neimyer, the hot weather, poor food, the fleas and other troubles we suffered considerably. This, of course, pleased the captain. We had to take our bath in the horse trough and had no soap.

"People in this country who think the war has affected them have no idea at all of what the people in Germany are enduring. Everything is being sacrificed for the needs of the army. There is such a scarcity of leather that the majority of civilians now wear either wooden shoes or shoes with a flexible steel sole. Clothing is very scarce and high priced. Food is the worst, though. The Germans who are not fighting fare very badly. Our sentries were generally old men unfitted for active service and I have often seen them go to the garbage piles in the camps and endeavor to scrape out from tins which had reached us through the Red Cross little scraps of fats or grease. Not infrequently loaves of bread which had been sent to us would reach us in a blue, mouldy condition from delays in transmission. It was unfit for us to eat and when we threw it away the loaves would be eagerly taken by these men. "While we were not allowed to mingle with the civilians, we could judge of conditions from the walks we were permitted to take on giving our parole not to attempt to escape. There was unmistakable evidence in the pinched faces of the people, their tattered clothes, the wan and sickly looks of the women and children that they were being deprived of the essentials of life.

"It is this sort of thing that is weakening the courage of the German people. When they find out what they have been compelled to suffer and how they have been misled by the militarists there will be a great reckoning."

From Holzminden Captain Morrison was sent to Heidelberg and on account of his physical condition arrangements were made to send him to Switzerland. With 90 others he left Heidelberg at 3 o'clock in the morning and was taken across the border. From then on all was smooth sailing and he was sent from there to England and from there home.

"GARABED" THEORY IS SHOT TO PIECES

Commission Don't Give Him Any Encouragement Following His Demonstration

A matter that was attracting considerable attention by engineers and scientists has been settled. A representative body of men representative of the best that United States has in the way of research and technical knowledge, have decided that the "Garabed" principle is not sound. The finding they have handed out is put in very lenient words.

For a time after the tests were made there was a bit of hope that there might be a favorable report on the case, but that was entirely dissipated when the official report came out in the Official Bulletin published at Washington. The report does not give Mr. Giragossian much hope of further encouragement. Nothing has come out to show exactly on what principles he was working. In fact the secrecy in which he was working is carried out in the report issued by the Department of Interior. It could hardly say less and say anything at all.

Following is the official signed report:

We, the undersigned, who are members of the commission duly appointed in accordance with the provisions of public resolution No. 21, Sixty-fifth Congress, hereby certify that Mr. Garabed T. K. Giragossian showed us on Saturday, June 29, 1918, a model embodying the principles of his invention known as the "Garabed." We found that the model was not in shape to run or develop power. The inventor admitted that he had no working machine and that he was merely explaining principles. We do not believe that his principles are sound, that his device is operative, or that it can result in the practical development or utilization of free energy.

Witness our signatures at Boston, Mass., this 29th day of June, 1918.

James A. Moyer, director, Massachusetts State Board of Education.

Edward F. Miller, Massachusetts Institute of Technology.

M. de Kay Thompson, Massachusetts Institute of Technology.

Edwin B. Wilson, Massachusetts Institute of Technology.

Hamilton, Ont.—The E. T. Wright Co., of Hamilton are contemplating the erection of a 150 ft. by 56 ft., one story and basement addition, to their present factory. The building will be so constructed as to permit of further extension should occasion require.

Repeated Impact Test Gives the Best Results

Various Devices Have Been Brought Out to Secure Accurate Temperature Control — Dr. Stanton Has Done Some Valuable Work in This Connection—A Wide Field in Which to Experiment

CLOSELY connected with the question of heat treatment is the subject of mechanical tests upon the treated material. Attention has been recently directed to the very great importance

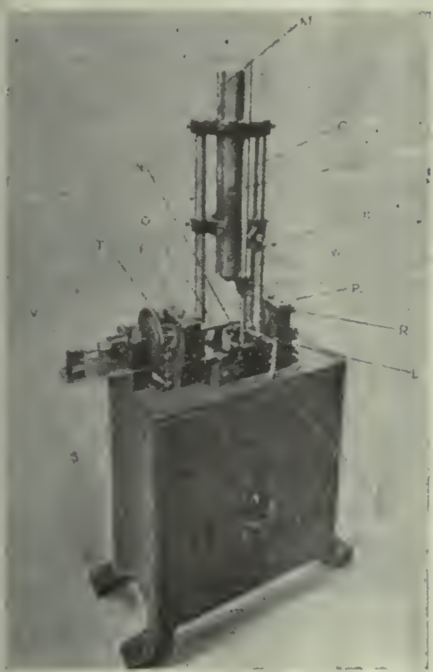

FIG. 4.

of such mechanical tests. It is not proposed here to enter deeply into the question of hardness tests, but experience suggests that the form of test most frequently used does not necessarily indicate what will be the resistance of the hardened surface to the abrasion to be met with in ordinary wear. In those tests which base the measurement upon the rebound of a weight from the hardened surface it appears possible that the mass of the hardened piece enters into the measurement, and it is suggested that figures attained in this manner should be regarded primarily as comparative between pieces of the same mass. Of course it is very clearly recognized that this comparative information is extremely valuable and these remarks are only made as a suggestion for further investigation.

A variety of tests are now made upon materials used in engineering work—for instance, tensile strength, elastic limit and yield point. There is also the single impact test, for instance, the izod test. It is found, however, that when you have all the data which these tests can give that there may exist large and critical differences between two materials, whose tests are apparently the same, when these materials are subjected to actual use in a piece of mechanism.

To discover such differences, the repeated impact test is extremely valuable. It is probably well known that Dr. Stanton devised a machine for making such repeated impact tests in 1908, and experiments with his machine have shown that extremely valuable information can be obtained by subjecting the material to a succession of shocks or impacts of a known amount, each shock being small individually, but the cumulative effect resulting in the breakage of the sample.

In the various forms in which this repeated impact testing has been worked out certain disadvantages were found with regard to the detail arrangement of the mehcanism. For instance, in one form it was found that the energy of the blow was not strictly calculable because it was uncertain how much mass was operating. The hammer which delivered the blow was attached by a lever, and it was impossible to calculate exactly how much of this lever entered into the effective mass of the hammer. It was further found that the nature of the surface upon which the machine was mounted influenced to a large extent the resulting figures.

Repeated Impact Testing Machine

To get over these difficulties, Mr. C. G. Eden worked out a design of repeated impact machine, and in conjunction with him I have developed the machine illustrated in Fig. 4. The hammer is without attachments, and falls freely under the influence of gravity, the whole falling mass of the hammer is symmetrically disposed above the point of impact, and the actual height of the fall may be measured easily, so that the true energy of the blows is calculable to a high degree of accuracy.

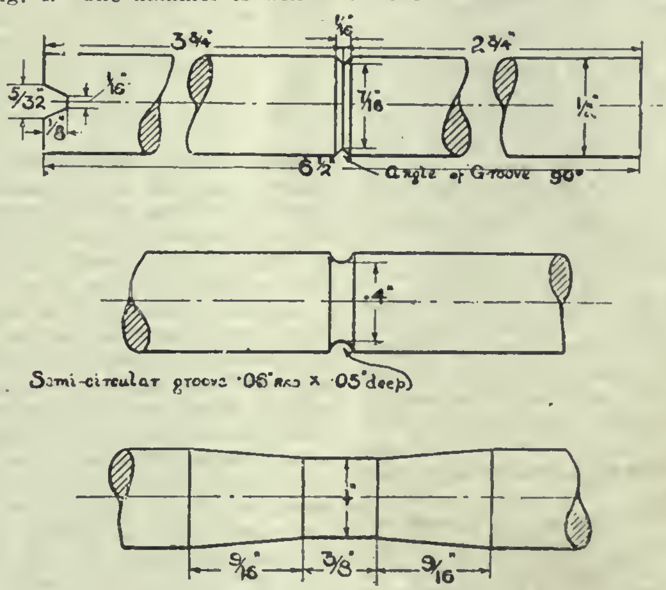

FIG. 4.

The base, which supports the test-piece, is massive and rigid; it will therefore experience only a negligible movement or deflection during the time in which the falling hammer delivers its blow. For this reason it is immaterial to the results attained whether the machine be mounted on a concrete floor or a wooden bench.

To demonstrate this feature of the design, the tests tabulated below were made under extreme conditions. In the first two tests, marked "rigid," the machine was firmly bolted down on a concrete floor, while in the remaining two, marked "floating," the machine was loosely supported upon a bed of folded canvas strips five inches wide, set up on edge. This last condition was the most non-rigid mounting that could be contrived. The material tested was an alloy steel, the samples being cut from the bar as it came from the mill and not subjected to any heat treatment. It will be seen that, notwithstanding the extreme conditions of mounting, the results are in very fair agreement.

Sample No.	Condition of Machine	Number of Impact Blows	Dep. from mean (1138 blows)	
1	Rigid	1104	— 34	— 3.0%
2	Rigid	1120	— 18	— 1.6%
3	Floating	1186	+ 48	+ 4.2%
4	Floating	1142	+ 4	+ 0.4%

The illustration in Fig. 4 gives a general idea of the external appearance of the machine. The whole of the mechanism is secured to and supported by the main casting, which also acts as a cover to the tank or box casting. Projecting through the side of the tank, but not seen in the ilustration, is the main spindle. This may be driven by a 1-in. belt from any convenient countershaft, or alternatively by an electric motor with suitable gear or worm reduction. The power required is about one-tenth horse-power.

Mechanism

The main spindle carries a dog clutch normally in engagement and driving a cam. A roller bears on the upper surface of the cam and is attached to the lower end of the rod H. It is so guided that it rises and descends at each rotation of the cam. Fixed on the rod H is an arm J, which engages with the lower face of the hamer M, thus when the rod H rises, by rotation of the cam, the hammer M is also lifted. The hammer slides freely between two sets of three-point guiding screws, these screws being carried by the two castings seen attached to the standard G and its fellow on the opposite side.

Mounted upon the standard G is a sleeve W, free to rotate about the standard but normally held in a fixed position by the spring L. Clamped on the sleeve W is an adjustable catch K. As soon as the arm J has lifted the hammer M sufficiently, the spring L causes a partial rotation of the sleeve W, so that when the arm J descends, the hammer is held by the catch K. The lower inclined face in engagement with the roller arm N, attached to the sleeve further descent of the arm J brings its W. in such a manner that the catch K releases the hammer M, allowing it to fall upon the test-piece O.

The test-piece, the size and details of which are further discussed below, is carried by two hardened steel bushes in the plummer blocks PP. It is rotated through 180 deg. between successive blows. One end of the sample is slotted to engage with a universal joint drive, and is kept in engagement by a screw R. The universal joint is driven through a free wheel and clutch T by the chain S. One end of the chain is attached to the roller bearing on the cam already described, and the other end carries a weight suitably guided; the rotation of the test-piece begins and ends entirely between the successive blows.

The revolutions of the test-piece are recorded by a counter V. and of course, the number of blows is found by multiplying the counter record by two. When the test-piece breaks it comes in contact with an arm X, and thereby trips the clutch and stops the machine. The tank is partially filled with oil to provide efficient lubrication of the cam and other surfaces.

The hammer is shod with a tup of hardened tool steel. The height of the drop depends on the position of the adjustable catch K on the sleeve W, and may be varied from one to four and a half inches (25 to 113 m/m). To allow a wide range of tests, two hammers are provided, weighing 5 lbs. and 2 lbs. (2.26 and 0.91 kilos) strength.

Using the 5 lbs. hammer, the main spindle may be driven at any speed up to about 60 revolutions, or with the 2 lbs. hammer up to about 90 revolutions per minute, giving 60 and 90 blows per minute respectively.

Test Pieces

The machine is adapted for test-pieces of dimensions similar to those adopted by Dr. Stanton; these are illustrated in the upper diagram in Fig. 2. It will be seen that a V notch is cut in the region of impact to localise the stresses. The angle at the bottom is 90°, and is made as sharp as possible. As an alternative, a semicircular groove, as shown in the middle diagram of Fig. 5 may be used, and such a groove appears to offer several practical advantages over the V groove. Referring to the upper diagram in Fig. 2, it may be assumed that the action of the hammer, when it falls upon the test-piece, is to produce a very slight but sudden bending at the section of smallest diameter, that is, at the bottom of the groove, as indicated diagrammatically in Fig. 3. This will produce an area of compression at "A," and will tend to start slipping between the crystals, due to tension, at "B." Of course the process is reversed at the next blow because the test-piece has been turned through 180° in the meantime.

It will be admitted that it is quite impossible to turn a groove having a true

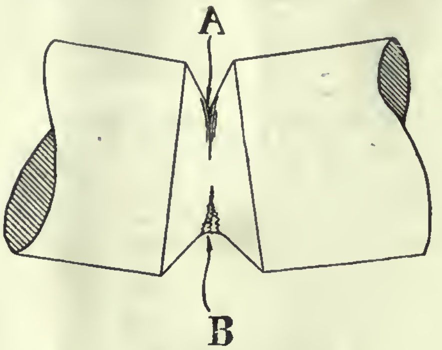

FIG. 5.

geometric angle, there must be some minute curve at the bottom of the groove. The size of this curve will determine the axial extent of the regions of compressive and tensile stresses. Since this size is in any case very small with a nominally sharp V, it is obvious that the variation between the size of curve in different test-pieces will be relatively large and will tend to introduce an element of uncertainty into the test results. It may be argued, in addition, that since no capable engineer would design a machine with a sharp re-entrant angle the conditions of test are largely artificial.

Another shape of sample has been proposed, as shown in the lower diagram of Fig. 2, having a relatively large portion of reduced diameter, but this is not advised. The end of the tup of the hammer, being a plane surface, will bear upon the test-piece over a considerable length parallel to the axis of the test-piece, and it is probable that, owing to the minute bending of the sample, the local stresses at the ends of the area of contact are greater than at the plane equi-distant between the points of support—in fact, it has been found with test-pieces of this shape fracture will begin at the point coinciding with the end of the area of contact between the tup and the test-piece. There is a further disadvantage that the action of the blow will distort the cross section of the material at the plane of fracture.

The semi-circular groove, as shown in the middle diagram in Fig. 2, is free from the disadvantages of both of the other types. It serves to locate the plane of fracture sufficiently closely, the effective diameter at the bottom of the groove is measured easily, any small departure from the nominal curvature is without practical effect upon the results and the actual area of fracture is not distorted by the hammer blows. Re-entrant angles are frequently designed in machines with a fillet of such radius, therefore the results have a more direct bearing on actual engineering practice.

The following tests were made to investigate the effect of the shape of the groove. The material was a commercial mild steel, annealed by heating to 900° C. and cooling in the furnace. The tests, as a whole, demonstrate the relatively unreliable nature of commercial mild steel. They show clearly, however, the greater approach to uniformity with the semi-circular groove, they also show the small influence of large variations in the curvature of the groove.

Sample No.	Diam. at bottom of groove. inches	Shape of Groove.	Radius of Grove. inches	Number of Imp. Blows
3	0.400	Sharp "V"	——	8
4	0.400	Sharp "V"	——	188
5	0.400	Sharp "V"	——	260
6	0.400	Sharp "V"	——	70
7	0.400	Semi-circular	0.06	548
8	0.400	Semi-circular	0.06	590
9	0.400	Semi-circular	0.04	410
10	0.400	Semi-circular	0.04	484

As an indication of the valuable information to be obtained with this repeated impact machine, the summary of tests in the table below is interesting.

Mater.	Izod Impact Ft. lbs.			Eden-Foster Repeated Impact No. of Blows.		
	Max.	Min.	Mean	Max.	Min.	Mean
A	104.7	90.7	97.7	584	458	521
B	71.7	45.0	58.4	1478	782	1140

These results show that the "Izod" test does not, by itself, give a reliable indication of the dynamic respectively.

MAY TRANSFER ROYAL NAVAL COLLEGE

THAT the decision has been practically reached to transfer the Royal Naval College from Kingston, Ont., to Esquimalt, B.C., is the announcement made recently through the offices of the capt.-supt. of the Esquimalt dockyard. The naval college, which was removed to temporary quarters at Kingston following the disaster last December, is to be transferred here temporarily, pending the erection of new college buildings at Halifax. It was announced that the naval students will be accommodated in one of the large buildings available in the Esquimalt dock yards, which can easily be converted for the purpose. It is understood that the naval students will be installed at Esquimalt by August.

Method of Estimating Cost of Machine Work

The Manufacturer Cannot Continue to Stay in Business and Estimate Too Low—Some of the Irregularities That Come Into the Question of Figuring on Jobs For the Trade

By DONALD A. HAMPSON, ASSOC. MEM. A.S.M.E.

UNDER this heading a construction engineer relates his experience in getting bids on some castings and machine work. The work was for replacement on some hydraulic equipment for a large city; bids were asked from a dozen shops, nine of which quoted their hourly rates and the other three quoted prices of $750, $1,020 and $1,890. Evidently the wide variance in these three latter rather peeved the engineer for he goes on to say . . . "cannot take a drawing and make an estimate from it" . . . "when a job is taken to a contract shop, expect to be overcharged as a matter of course," . . . "small manufacturers with their inefficient methods," etc. Such remarks ought not to go unchallenged, and having been in the despised small manufacturer class I will present some of the points from the other side.

Afraid of Fair Price

It is an undeniable fact that many manufacturers and many machinists are unable to estimate the cost of a given piece of work; it is also true that many manufacturers (small ones only) are afraid to ask a fair price for their work in advance and to add a margin for safety to cover those little necessary uncertainties and losses which are reasonably sure to crop up. Without a doubt, the nine replies that named no price came from shops in this class, and it must be said from their standpoint that they were justified in quoting only hourly rates, while the shops themselves may have been run efficiently and the management been entirely honest.

The three bids of $750, $1,020 and $1,890 likewise may have been made with all honesty, the $1,020 bid probably representing a fair average price and the others extremes either way. It is easily probable that the difference in prices has come from different shop equipment and methods and different market prices for labor and materials in different localities. Such being the case, each shop bid a fair price and is justified in sticking to it. It is safe to assume that the fees of consulting engineers vary fully as much—yet the man with a Broadway suite is fully as honest and as capable as his struggling brother in the north-west whose bid is fifty per cent. less.

In the case that we are considering a complaint was made about the slowness with which the bids came in. It is easy to settle that and the answer sheds some light on the widely different prices, too. Many, many drawings do not state the limits which the machinist and the estimator must know, which denotes certain finishes and fits, and which are supplied with all the notes that any man, other than a mind reader, should have before an intelligent estimate can be made. Such shortcomings are to be expected on the drawings of inventors and laymen, but the work of engineering departments is open to criticism at times also as witness the following.

And in Three Days!

The largest steel and machinery firm in the U.S., outside of several trusts, found its plants overtaxed and decided to put several of its products out on contract. Our shop asked for a chance to bid on some of the work, and received a fifty pound roll of prints and a letter stating that "we must have your estimate in three days." The work amounted to a hundred thousand dollars, and could be spread out over seven months —the estimate though must be hustled. Imagine our surprise when an examination of the prints showed sixteen letters denoting sixteen different finishes, but no key to the finishes being shown on the prints. Hence we knew no limits and finishes except by guesswork. Further, steels and bronzes of special analyses were required, standard bolt and nuts were carefully detailed—presumably to be made up, though a dozen machine screw manufacturers kept them in stock—and even locks that could be found in hardware catalogues were detailed. What kind of an estimate could be made on such information? Only a few weeks ago an engineer asked us for a figure on forty-eight 15 in. cylinders, and his drawings failed to show a finish on the outside, which would add forty per cent. to the labor (a finish that we guessed he wanted, and that he really did).

All of which is not intended as a knock, but just to show that "much might be said on both sides," and that a spirit of tolerance and co-operation is of mutual advantage. I should have liked a chance to bid on the drawings which raised the question, but I contend that because my price was higher or lower than the others or the engineer's guess, it would not mean that any of us was wrong.

No Standard of Prices

There is such a thing as a fixed standard of accuracy which is good the world over, but no standard of prices, yet on work which is not made in quantities, two men on the same block might make widely different estimates, and both of them be correct for their own shop. It's all a matter of equipment and ingenuity on these jobs of a few pieces, modified by the local scale for commodities—cost systems and efficiency methods here count for but little if the shop force is well directed. System and the proper tools and large quantities will make the cost per piece the same in the East as in the West—but that's another game.

That first class shops "slip up" on this estimating problem may be proven by two instances. An Ohio manufacturer whose equipment and men have always been the best that money could get, and whose line was as near to shell work as any could be outside of the military field recently gave a talk before an engineering body, relating their experience on a shell contract in 1915, how their estimates were far too low, their deliveries six months behind, and unlooked for troubles all along the way. If first class men with every facility can't estimate duplicate work in big quantities is it fair to brand as inefficient small manufacturers who incorrectly estimate the time on a single piece? Another, an Eastern machine tool plant took on some contract work for an automobile concern. Both firms have a nation-wide reputation for good work, one in the small lathe field and the other in the $5,000 car field. The machine tool firm lost nearly 50 per cent. on their contract, presumably because they, too, "cannot take a drawing and estimate from it."

Defends the Machine Shop

There are many machinists that will resent the slur on contract and jobbing shops and their charges. Granted that there are unscrupulous men in the machine business as in every other, that there are city shops running in cellars that never see the light of day, and country shops doing business in converted barns with a junk pile supporting one outside wall (this combination known as the "foundry"), yet the majority of city and country shops are honestly run, and rank far above establishments in the building trades which do not come in for such slurs. One marked difference between the machine and building trades is that the former work the longer hours, under stricter supervision, must deliver of a skill and intelligence of a high order, and the shop and men get less per hour than in a branch where the entire "trade" can be learned in a month. The employer in the former case has to provide equipment of the most expensive and extensive kind. has to figure a job down to the last five cents, and is subjected to a multitude of useless factory laws that tempt him to sell out and put his money in the savings bank.

Yet, because the contract shop charges for the time it took to collect and put away tools and blocking, for the set-up on a single job, and for the six hours setting up as well as the two hours that it took for the actual cut, it is over-charging. I have had a man contend that, because he was charged the same for a cut .005 in. deep a for one ⅛ in. deep, he was overcharged, his contention being that the work was so much less in the one case.

Can't Figure Too Low

The facts in the matter are these: any small manufacturer is in business to stay if he can and he will meet his customers half way both in charges and estimates, but he cannot continue to figure too low and stay in business. Maybe the equipment of one shop is such that it can do boring to better advantage than any other kind of work, but the shop will take other work as it comes along and charge the usual rates for it by the hour, it cannot be expected to do this other work for the same price as a specialist in that particular line. The proprietor is honest and so is his loyal gang of men who work more minutes to the hour than any plumber who ever came down the pike, but to live they must at least break even on their work. I have had a painter complain about the brushes he had to buy for his men; his equipment ended with brushes and ladders, mine began with machine tools and high-speed steel and drills (and included brushes as a minor item) and yet in our locality working painters got 20 cents more an hour than machinists and charges for work were in proportion. If the small manufacturer got a little more of the $1 to $2 an hour work he wouldn't remain a small manufacturer long. Doctors and lawyers are entitled to their fees whether they win or lose —why should not machine shops get a fair price when they have to win to collect at all?

ECONOMIC STEP BY ENGINEERS

The Canadian Engineering Standards Committee, constituted with official representation from the departments of the government, the Canadian Manufacturers' Association and the important technichal organizations, has been formed in Montreal, and will be of paramount importance in economic production in Canada. It will also have the effect of harmonizing British and American practice. Its primary objects are to secure interchangeability of parts, to cheapen manufacture by the elimination of waste entailed in producing a multiplicity of designs for one and the same purpose, to effect improvement in workmanship and design, and by concentration rather than by diffusion of effort to expedite delivery and reduce maintenance charges, and storage.

At the organization meeting Sir John Kennedy, the dean of the engineering profession in Canada was unanimously appointed chairma, and P. H. Vaughan and Capt. R. J. Durley vice-chairmen. Dr. John Bonsall Porter was elected honorary secretary-treasurer, and Frank S. Keith, secretary. The headquarters of the organization will be at the Engineering Institute Building, 176 Mansfield street, Montreal.

THE INDIVIDUAL DRIVE BECOMING MORE POPULAR IN ENGLISH SHOPS

By P. E. R.

Individual motor drive for metal working tools is becoming standard practice and it is interesting to note some of the applications of electric drive as developed in England.

The drawing Fig. 1 shows a curve of a machine arranged for self-contained electric drive, single speed, through gearing and motor mounted on top of the machine. A strong cast iron framework is attached across the machine standards, and the whole driving gear is mounted on planed faces on this casting. A compound wound motor of 35 b. h. p. with starter is used to drive a 5-foot square machine to run at approximately 600 revolutions per minute.

The two gear wheels run in an enclosed oil bath and the two shafts are supported in self-oiling bearings, with provision for returning oil running out of same to the reservoir. The quick return of the table is operated by the motor shaft extension, so that the gears do actual work during the cutting stroke only. It will be noted that no crossed belt is necessary.

Fig. 2 shows a 5-foot square planing machine, fitted with an English electric planer equipment, while illustration Fig. 3 shows a 4-foot square planing machine to plane 10 feet long, fitted with a special four-speed countershaft, self contained electric drive, the motor being directly coupled to quick return shaft. The size of motor used with this machine is 20 b. h. p. compound wound, and runs at approximately 400 revolutions per minute.

It is said to be possible with this drive to obtain cutting speeds of approximately 30, 40, 50 and 60 feet per minute with a constant return speed of 90-100 feet per minute. All the bearings in this machine are self-oiling. Each turn of the hand wheel shown on the photograph gives a different cutting speed without stopping the machine. There is no unnecessary friction and no claw clutches. There are no sliding gears to break and no noisy gears, nor leaky gear boxes to drop oil on to work before the finishing cut is taken.

The accompanying curves Figs. 4 and 5 were taken with a Lancashire electric drive ,which is said to be economical in power and has a perfect regenerative and cushioning effect at reversal. On a belt-driven planer the reversal of the pulleys and the consequent slipping of the belt causes a large amount of power to be wasted at each reversal This waste becomes larger as the stroke is decreased.

In order to prove this the following tests have been taken on the two rack driven planers (1) A 5 ft. 6 in. x 3 ft. 6 in. x 12 ft. planer was arranged with motor belt drive and three flywheels for reducing the peak and assisting the reversal. (2) A 4 ft. x 4 ft. x 12 ft. planer was equipped with a "Lancashire" drive and in both cases the cutting speed was 50 ft. per minute and return speed 150 ft. per minute. The load on the bed slides in each test was 4 tons.

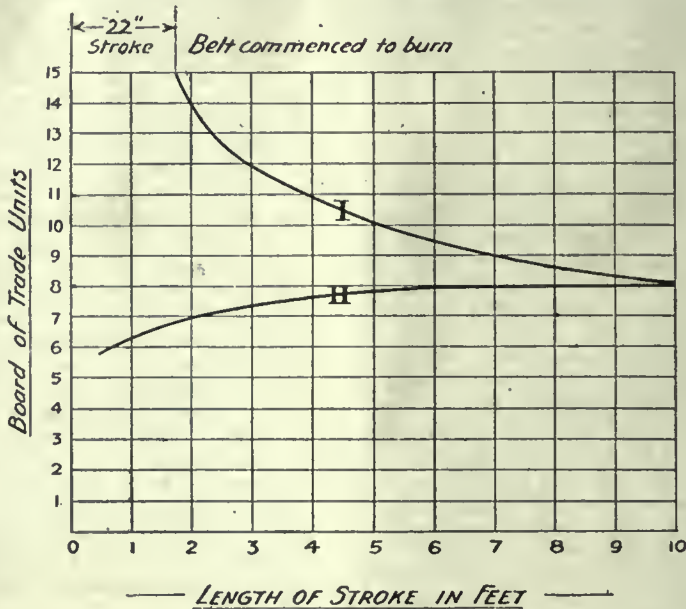

FIG. 1.

The test was made with a watt hour meter and the curves show the total power taken from the mains in both cases with various strokes. In the above tests the electrical machines were only partially loaded as the planers were not cutting, therefore under ordinary working conditions the efficiency of the "Lancashire" drive as compared with the belt drive would be still more pronounced.

F. W. Field, British Board of Trade Commissioner, has just completed a tour of all Ontario manufacturing centres.

THE MANUFACTURE OF TACKS

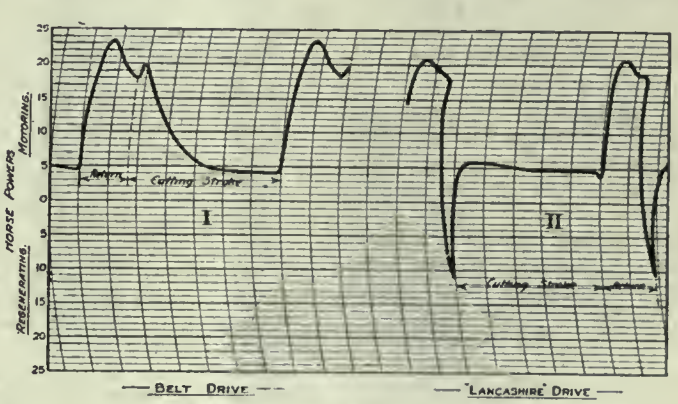
THE majority of users of the humble tack have no conception as to the amount of work involved in its production or the number of processes that are necessary to produce this common but very important article. To look at a tack one would hardly believe that so much expenditure of labor and skill was necessary in its manufacture, but in reality such is the case. The fact that tacks are manufactured in large quantities on a high-production basis enables the manufacturer to operate his plant profitably in spite of the low cost to the consumer. The amount of profit depends to a large extent upon the layout of the plant and methods employed. These methods, while being very similar in most plants vary in certain particulars which may be termed trade secrets. Most tack manufacturers have methods of their own which are carefully guarded and which are claimed to affect considerably the earning capacity of the plant and the quality of the product, both very important factors in these days of keen competition.

The tack plant which the Steel Company of Canada, Ltd., operates at its Canada works, Hamilton, Ont., is run on a highly efficient and profitable basis.

The company furthermore has this advantage that it rolls its own sheets or tack plate, to use the trade term, and is thus assured both as to even quality and regular supply of the raw material. The tack plate which is rolled at the company's principal plant at Hamilton is made in certain definite sizes and in gauges ranging from 21 to 10, the size and gauge varying according to the size of tack to be made from the sheet. The sheets are delivered to the Canada works in bundles and are stored there until required.

Pickling and Baking

The sheets at this stage carry a certain amount of scale which must be removed. This is done in the pickling process. The sheets are laid in racks, end up, and dipped in tubs containing vitriol, a fairly strong solution of sulphuric acid, which removes the scale and makes the sheets bright and clean. The rack, with its load of sheets is then lifted out and placed in another tank containing lime, which removes the acid adhering to the sheets. The sheets then undergo a baking process which restores the material to its normal condition and neutralizes the effect which the acid has had on the physical properties of the steel. The baking is done in coke-fired ovens heated to a high temperature. After baking the sheets are ready to be converted into tacks in another department.



Test taken with Recording Ammeter.

FIG. 4.

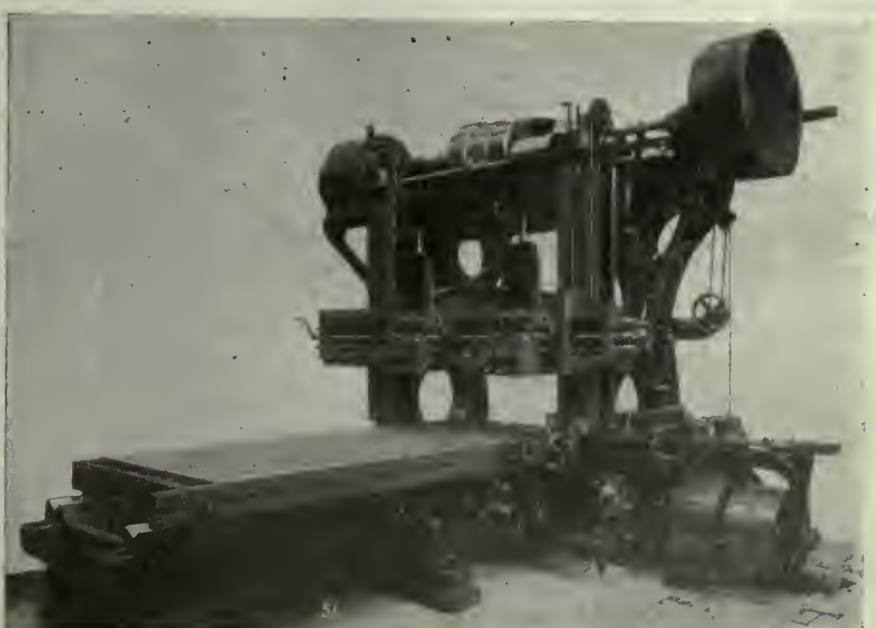


FIG. 3—A 4-FT. ENGLISH SQUARE PLANING MACHINE WITH 4-SPEED COUNTERSHAFT AND SELF-CONTAINED ELECTRIC DRIVE.

Making the Tacks

The tack machines are arranged in long rows, the material being fed to the machines in the form of strips by boys who can take care of three or four machines each. At one end of this room is a power shear for shearing the sheets into strips of varying widths according to length of tacks into which they will be converted. For the same reason the gauges vary. The tacks are made from

⅛ in. to 1⅝ in. long, inclusive. The tack machine, which is rather a complicated piece of mechanism, operates at a high speed, accompanied by considerable noise as the process is more akin to stamping than anything else. The most important feature is the timing and adjustment of the tools in the machine. There are ten tools in each machine, and each tool must get to a given point and away again to allow the next tool to do its part of the work. Needless to say this requires very careful adjustment, particularly on account of the high speed and nearness of the tools to each other. The strips are placed on the machine by the operator and then are automatically fed with tools, the tacks falling into a pan underneath the machine.

Varieties of Tacks

Tacks are made in various finishes, bright, blued, galvanized, tinned, copper, brass or nickel-plated, coated and Japanned. Blued tacks are obtained by heating them in a blueing machine or heater. The bright tacks are first annealed and then passed through tumblers which gives them the bright finish desirable for certain purposes. The galvanized, tinned and plated tacks are treated by being dipped in the ordinary way.

Picking Process

The next operation is an important one, particularly as far as the consumer is concerned for the public demands perfect tacks. During the process of converting the steel strip into tacks there is a certain amount of unavoidable wastage, because the two ends of the strip being square will not make tacks. These ends come through with the good tacks and have to be eliminated in the picking process.

The picker is an inclined revolving screen, a different screen being used for each size of tacks. The defective work falls through the holes in the screen and the good tacks pass down inside and fall into a box at the bottom. The good tacks are then taken to the packing room and put up in bulk, 25 lb. and 50 lb. boxes, cartons, etc., according to the requirements of the customer. Before being packed the tacks are all weighed so that each box, carton or package contains the correct amount of tacks. The boxes, etc., are then stored until shipped.

The tacks are made in a large number of varieties and sizes for various trades. In many cases the form of the tack varies, but the process is the same. The form and size of the tools employed in the tack machines vary in proportion to the variety and sizes of tacks manufactured. For this reason a considerable amount of work is involved in making the tools for the machines and in keeping them in good working order. The tools must of necessity be correct in form otherwise unsatisfactory work would be the result.

Orangeville, Ont.—Dods Knitting Co. will erect a $40,000 extension to their plant.

MINING DISCOVERY MADE IN CANADA

The Forest Products Laboratories of the Forestry Branch of the Department of the Interior have found a substitute for pine oil, now in such demand for the reduction of ores by the oil-flotation process.

What the oil-flotation process means to the mining world is shown by the statement of a leading mining journal that a certain great mine, which formerly recovered 70 per cent. of the metal from its ores, was now, by this process, recovering 90 per cent.

To work this process there has been required up to the present pine oil extracted from the "hard" pine trees of the Southern States. The erection of oil-flotation plants all over the United States so increased the demand for pine oil that the price went rapidly bounding upward, and it seemed as if in a short time the supply coming across the line to Canadian plants would be entirely shut off.

Work Done by Canadians

Cobalt is one of the districts most concerned, and some of the aggressive operators there started experimenting in the way of trying to make for themselves a pine oil from Canadian stumps. While these experiments were not barren of results by any means, the miners quickly realized that this was the work, not of miners in small experimental plants, but of specialists in well-equipped laboratories. They therefore applied to the Minister of the Interior, who, having established about a year before the Forest Products Laboratories of the Forestry Branch for just such investigations, started the laboratories to work on the problem.

The work was done by Canadians. It achieved its twofold object. The chemists found that they could make pine oil from red pine stumps, such as may be seen any day on a trip on any of the railway lines running through the "pine plains" on which Camp Borden is situated. Had this been the only discovery it would mean that Canada would have had in this time of war to establish a new industry involving the collection of pine tree stumps over a large area and assembling them at one place for distillation. It is possible, but not likely, that such an industry may be established, as the amount of turpentine in the stumps of northern pine is limited, and pine oil is secured from turpentine by a second distillation.

Substitute Found

But the second object of the search was of still greater importance. It was discovered that one of the creosote oils, thrown off as a by-product of the hardwood distillation industry, would serve in the oil-flotation process equally well with pine oil. This by-product up to that time had so little market value that a good deal of it was burned for fuel. It is produced now at the rate of nearly twelve hundred gallons per day in Canada.

It seemed at first almost too good to be true that a comparatively waste product would take the place of the costly pine oil, but the new oil was thoroughly tested in the ore-dressing station of the mines branch, Ottawa, before public announcement was made. The result of this division of labor between the government and the miners is that the government chemists solved the scientific problem and the miners are now working out the practical application in their plants, with increase in economy and efficiency. The miners get a much cheaper material, and the wood distillation plants have now a market for another of the by-products of their industry. Both industries are naturally pleased with the result. It means also that money formerly sent abroad is kept at home to build Canadian industries.

WOULD REGAIN ONTARIO TRADE

British Columbia will reopen its Toronto lumber office. Some months ago L. B. Beale was recalled to Victoria and the office was closed because of war financial conditions. B. C. lumber interests have been conducting a very serious lobby to have this reopened, on the ground that all the good work done by the office has proved of great value to the B.C. lumber industry. The business connections created by the office went by the board when it was closed.

Just at present there is strong competition for Ontario business, of which the American lumbermen are getting the biggest share. The need for the resumption of an educational campaign to crease the use of B. C. lumbsr in Ontario has been forced upon the government of the far Western province, and an agitation was commenced recently to push the claims of the B.C. product in the Ontario field. It was felt that the demand in this province for Douglas fir and other timber from the coast was down to an irreducible minimum, and with the slump in wooden shipbuilding throughout all Canada this has caused a decision to expand the present markets.

Mr. Beale, who was formerly in charge of the Toronto office, has been appointed special lumber commissioner for British Columbia to Europe. He will seek to extend the market for British Columbia products in Great Britain, France and other countries. He will come East in the very near future, and will make a survey of conditions in Eastern Canada before departing for Europe.

Architects in Ontario have been extensive users of Georgia pine and other American woods for building purposes, and it was largely through Mr. Beale's work in the East that the British Columbia lumber began to win greater popularity. The Toronto office was closed at a time when B.C. lumbermen were too busy filling orders for outside territory to make use of the Ontario field to the best advantage.

The decision to institute another campaign is an important one to the building trades in Ontario, indicating that another Canadian industry is seeking to reestablish itself on a permanent basis after the unusual conditions occasioned by the war have to a large extent been altered.

FROM THE MEN WHO PRODUCE

Methods, Machining Devices, Systems, and Suggestions From Shop And Drafting Room

METHOD AND TOOLS FOR MACHINING A SPLIT RING

By F. Scriber.

An interesting example of machining by the use of special tools is described and illustrated in this article. The part to be operated upon is the split ring shown in Fig. 1. This ring is machined from a bronze casting, the operation of splitting apart being the last that is performed upon it, with the exception of burring.

In handling this piece it is first gripped in a three-jawed chuck, the hole is bored and faced, it is next gripped by the inside diameter and the opposite side is faced, these portions being indicated by finished marks. The outside is unfinished with the exception of filing and that part of the work which is of particular interest consists of drilling the holes, spot facing and cutting apart. For the drilling and reaming operations we proceed to drill by using a jig such as is shown in Fig. 2. The holes to be drilled and reamed are four in number, A, B, C, and D, Fig. 2. The ring is placed in the jig in the manner shown locating from the hole on the stud E. When the work is placed on this stud the slip collar F is slid in place and the work is securely clamped into position by means of a hand knob G. For radial location around the centre of the large hole the boss X is forced against the head of the bushing H by means of the thumb screw J, these arrangements locate the part so that all work produced in this jig will be interchangeable, suitable bushings as is obvious being used for guiding the drills.

The next operation on this part is shown in Fig. 3. This consists of spot facing the bosses where indicated and a very simple tool is provided in this connection. This tool consists of an angle iron A in which are placed two pins B and C; one of these pins C is flatted off on the side so as to permit of slight variations in the centre distance of the work. The part is slipped on to these two pins in the manner shown and the surface X is spot faced. To spot face the surface Z it is only necessary to slip the work off the pins, turn it over half a revolution and slip it back on again. It is not necessary with this tool to provide any means for clamping the work. The angle iron is of course clamped down to the drill press and by using a regular counterbore with a teat on it this operation is readily performed.

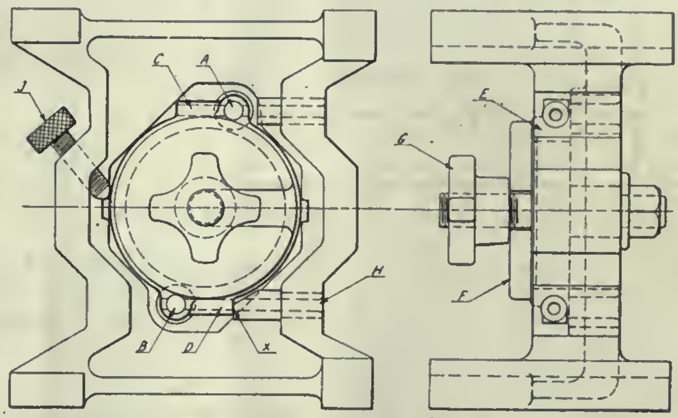

FIG. 2—JIG IN WHICH RING IS DRILLED.

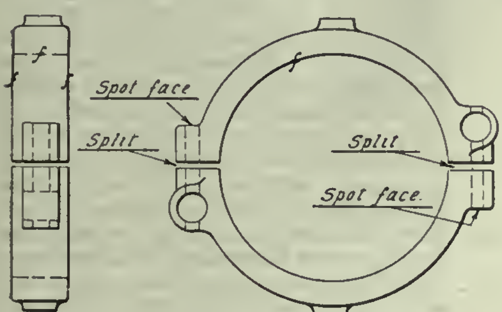
Having now completed the machining on the ring it is split in half on the milling machine, using the fixture shown in Fig. 4. The ring is again located on two pins A and B, at this time it is clamped to the fixture by means of the two clamps C, the clamps being constructed in the usual manner with nuts and washers D used for clamping purposes. The spring E is for holding the clamp up while the work is being removed. A headless screw G with a check nut J on it is used under the heel of the clamp while the base of the fixture H is made of cast iron. This fixture has two tongues F which fit in the slots of the milling machine table, and a slot K is cut across the top of the fixture as clearance for the saw which splits the ring.

These fixtures, while not expensive, are very efficient in operation and are a very good investment for handling such work in moderate quantities.



RING THAT IS TO BE MACHINED AND SPLIT.

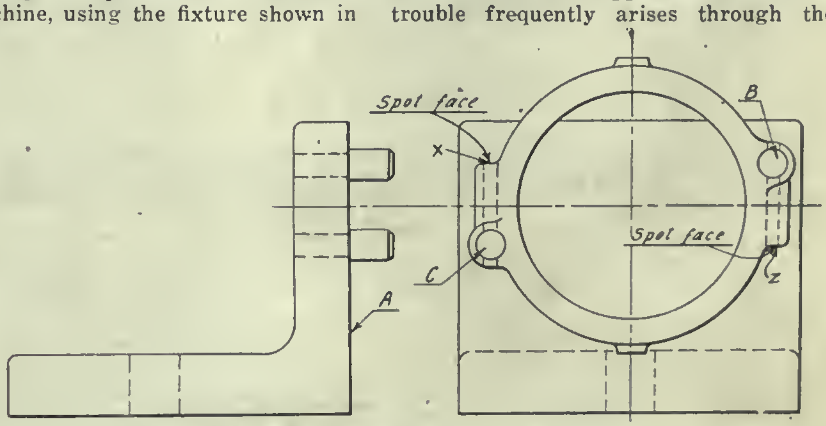


FIG. 3—FIXTURE FOR SPOT FACING.

COPPER BAND CRIMPING DEVICES

Rejected shells have often resulted from defective copper bands. This trouble frequently arises through the copper band being unevenly located when it is placed on the shell, the effect being to force the metal into the groove in an irregular manner, so that when the ring is subsequently turned it is found to be defective. A very useful tool that has been designed to overcome this ob-

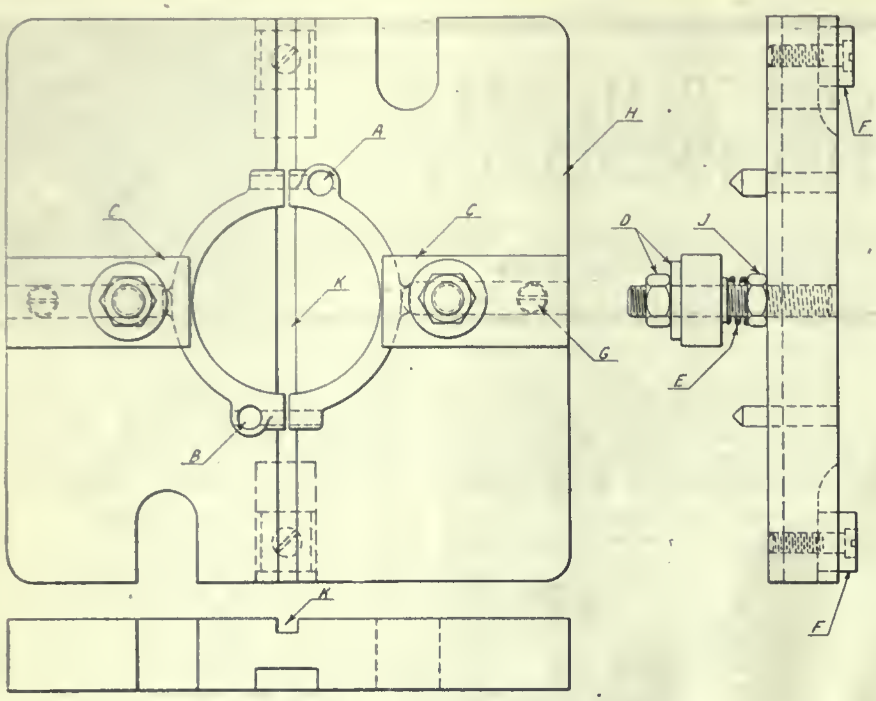

FIG. 4—FIXTURE FOR SPLITTING RING APART.

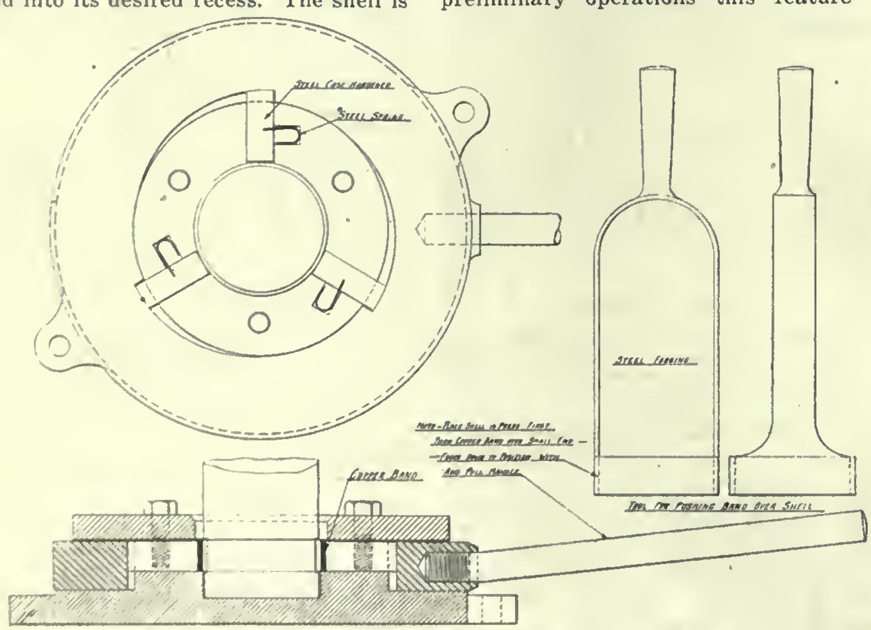
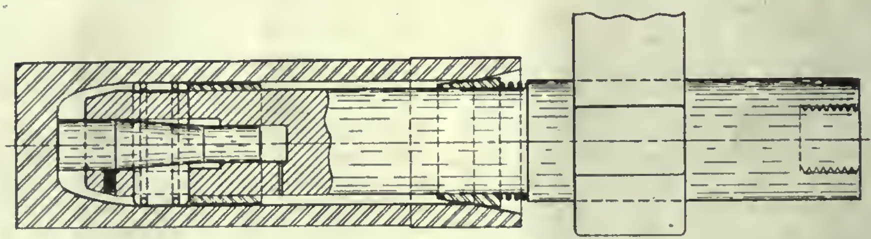
jection is shown in the accompanying line sketch. The purpose is to crimp the band correctly in position before the operation of banding in the hydraulic press. Where a large number of shells are handled the device has proved a great labor saver and also been the means of eliminating much of the trouble formerly experienced through defective bands. To operate the shell is first placed in the centre of the fixture and then the copper band is placed over the nose end, and tapped to the desired position by means of the steel forging that is designed to pass over the shell. The device is so constructed that the copper band can only be forced to a location in correct alignment with the groove. When in this position the handle is pulled around and the cam plate forces the cams inward, pinching the copper band into its desired recess. The shell is then removed and is ready for the hydraulic press operation. The entire operation occupies about 10 seconds.



DEVICE USED IN CRIMPING COPPER BAND ON SHELLS.

RECENTERING ARBOR

In the efficiency of shell production an essential factor is that of the concentricity of the walls after the machining has been completed. During the preliminary operations this feature is not so important as the operations that follow the finishing of the interior. It is necessary that the centre in the base upon which the final turning is performed, be placed in exact alignment with the finished bore of the shell, and in order to do this it is imperative that the tools upon which this operation is accomplished, be rigid and highly accurate. The arbor here illustrated has given very good satisfaction and the work performed has been of the highest quality. The shank of the mandrel is made to fit the spindle of a small lathe, the outer portion of the shank being supported in the steady rest shown. The open end of the shell is centrally located at the inner end of the arbor by the cone shaped ring which is forced outward by the action of the compression spring. This allows for any slight variation in the length of the shells. The cast steel plunger fitted into the nose of the arbor acts upon the three cast steel tempered jaws, forcing them out to the inner wall of the shell and bringing the same concentric with the axis of the arbor and also prevent undue wear upon the gripping jaws. Very little pressure is required to operate the jaws, and the pressure of the drill when working is sufficient to maintain the shell in position.



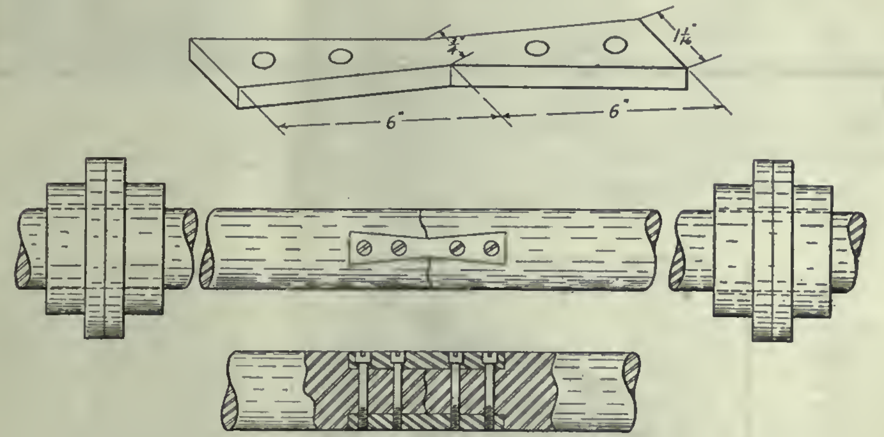
Two Hamilton boys, Duncan M. Stewart and Charles C. Dickson, have been appointed to prominent positions on the executive of the French-American Constructive Company, of New York, a concern, it is said, with unlimited financial backing, that has recently come into being for the purpose of facilitating commerce and industrial rehabilitation in the Allied countries as soon as the war is concluded. This company has been organized ostensibly to promote trade between Canada and the United States and the Allied countries, to act as distributors for Allied concerns wishing to have trade intercourse with either Canada or the United States, and to purchase direct from Canadian or American concerns for buyers in the European Allied countries. The Duponts—a name that stands for some substance in the realm of finance—are large shareholders of the new company. Duncan M. Stewart, manager of the company, is a brother to Charles Stewart, of the Hamilton civic waterworks department. Charles C. Dickson, vice-president of the company, who received his early business training in the offices of the old Great Northwestern Railway in Hamilton, is a son of M. C. Dickson, of the Consumers' Lumber Company, Limited.

REPAIRING A LINE SHAFT

By J. H. Houldsworth.

A main line shaft broke between two couplings as shown in sketch, and was repaired in the following manner:

The shaft was 6 inches diameter, and the repair had to be executed as quickly as possible. The first thing done was



to take a bar of steel and make two keys ¾ inch wide at the centre and 1 1/16 inch at the ends by ⅞ inch thick and 12 inches in full length. The keyway was drilled out with the shaft in place with a portable electric drill, then chipped out with an air gun and the keys made a good fit, two being placed diametrically opposite each other.

Four ½-inch holes were drilled and tapped in the shaft and fillister head screws were made with a long head to allow them to be screwed home tight.

Although a new piece of shaft was secured, we had no occasion to use it, as since the repair was made the whole thing was welded with a portable outfit which made a very satisfactory job and at a much less cost.

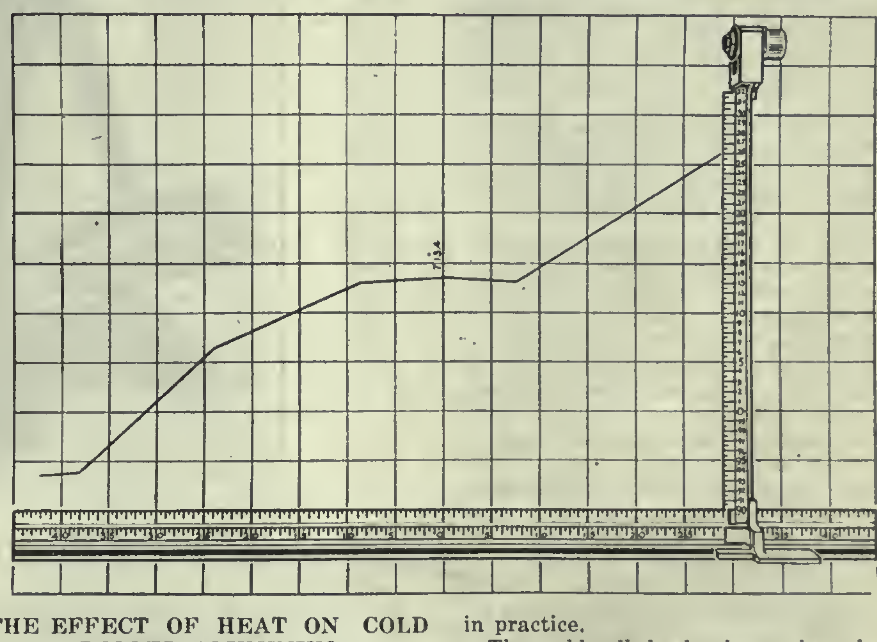
NOVEL CROSS SECTION PLOTTING SCALE

By Frank C. Perkins.

THE accompanying drawing shows the construction of a new cross-section plotting scale recently designed by Edw. A. Zorsch of Rochester, N.Y. The instrument consists of a horizontal piece and an arm. The horizontal part has a beveled straight edge, a scale, and a groove running longitudinally. The arm has a beveled straight edge with unnumbered graduation thereon, a looped flexible taper suitably graduated and made to move adjacent to the straight edge, and a spindle at the outer end by means of which the flexible tape can be moved back and forth. The inner end of the arm has a piece which fits in the groove of the horizontal member, and an index which cooperates with the horizontal scale.

It is pointed out that when using the instrument for plotting sections the horizontal member is placed with its straight edge on a horizontal line of the cross-section paper. The line is then given an elevation, after which the looped tape scale on the arm is moved until that number on the tape which corresponds with the elevation of said line is brought into coincidence with the line. The instrument is then ready to use.

It will be seen that distances to the right or left are read from the horizontal scale, while elevations are read directly on the arm. The use of this instrument lessens the error that is often made of counting the wrong number of squares, as distances and elevations are read directly on the scales. The instrument is adapted particularly for very rough, undulating sections. When plotting flat sections no vertical scale is necessary. With the use of this instrument sections can be plotted on plain, unruled paper.



THE EFFECT OF HEAT ON COLD ROLLED ALUMINUM

IN a paper read before the Institute of Metals by H. C. H. Carpenter and L. Tavener some interesting facts were brought forth relating to the behaviour of aluminum sheets when heated.

The effect of heating cold-rolled aluminum sheet at temperatures from 550 deg. to 300 deg. Cent. inclusive is to cause a very rapid softening of the metal as measured by the tenacity and the percentage elongation. As regards tenacity, the same ultimate value is reached in all cases. Softening is complete in 96 hours, and from 550 deg. to 350 deg. inclusive nearly the whole of this occurs in the first hour of the test. The elongation figures show a tendency to rise slightly as the temperature falls from 550 deg. to 350 deg.

At 250 deg. Cent. the rate of softening, while still considerable, is much less rapid. Between 600 and 800 hours are required for complete softening, and here also the same ultimate value of tenacity is reached as at higher temperatures.

From 200 deg. to 100 deg. Cent. inclusive the rate of softening is slow, and as the temperature of 100 deg. is approached, very slow. The actual sequence of changes can be classified conveniently under three heads:

(1) A comparatively rapid drop in tenacity in the first hour.

(2) A tendency either to cease falling or actually to rise, such rise, in one case only, bringing the tenacity up to the original value. This period is in most cases completed in 100 hours.

(3) A relatively very slow fall of tenacity sets in and is maintained on the whole steadily.

These tests are still in progress. Assuming the present rate of loss of work-hardness to be maintained, assuming also that the metal ultimately reaches the same tenacity as specimens tested at the higher temperatures, periods of the order of from one to three years will be required for completion.

It follows that no object is gained by using aluminum of this particular degree of work-hardness at temperatures which are likely to exceed 200 deg. Cent. in practice.

The cold-rolled aluminum has been shown to lose a considerable proportion of its work-hardness as a result of being heated in the temperature range, 200 deg. to 100 deg., with hardly any recovery of plasticity, as judged by the elongation test.

Le Chatelier's view that annealing a hard-worked metal was an easy thing to do was not borne out by the tests given in the paper, as far as aluminum was concerned. On the contrary, there was much evidence that Howe's view that many changes were going on concurrently was the fact with aluminum as with the other metals which Howe examined.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

FILING MACHINE

The filing machine illustrated has been designed by the Barry Manufacturing Co., Chicago, Ill., to fill a want in the tool room of a machine that may be used for filing, lapping, metal jig-sawing, etc. It is especially useful in making dies, punches, jigs, patterns, and gauges, and also provides a marked saving in finishing small parts. The features of the machine provide for much more rapid, accurate and smoother work than is possible by hand filing and insures a saving of at least 200 per cent. The patented file holder on this machine admits of using any file, regular or special, without other equipment; jig or hack saws can also be used for sawing out dies and templets. The machine throughout is constructed with reference to durability and convenience in operation.

The table is adjustable four ways, to give any angle or clearance required on any work. Indicator scales and needles attached to table permit of accurate adjustment.

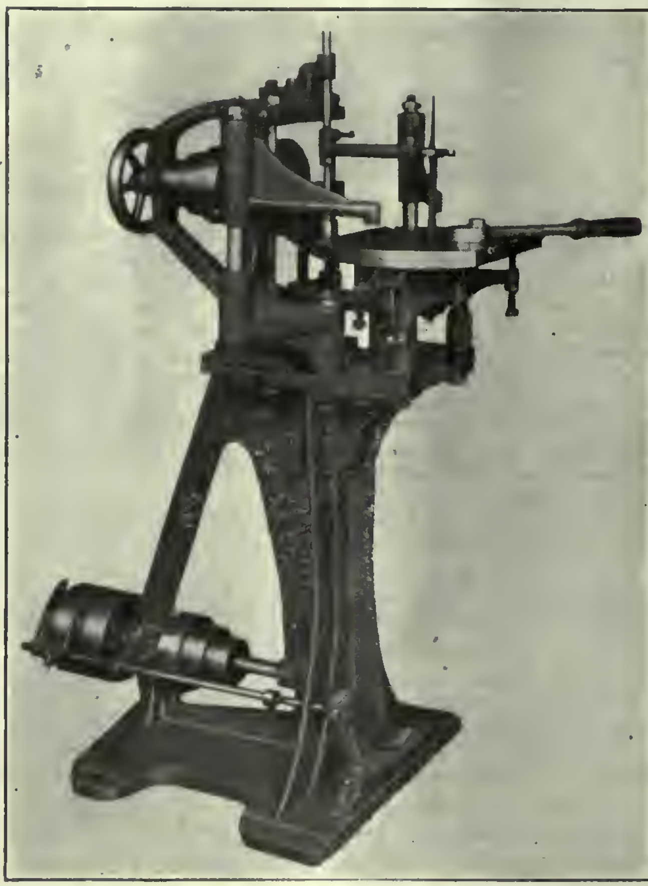
Roughing attachment provides a cam feed for fast roughing of dies and other work, and when not in use can be instantly removed.

Adjustable fingers on either side of table hold work firmly without marring and allow it to be moved freely in any direction on the table.

The ways are mounted above and to the back of work table; filings, emery powder or other abraders falling from work cannot deposit on the drive shaft or other working parts. Crossheads are slidably mounted on guide rods and carry file supporting arms adapted to operate below and above table; the distance between arms is readily adjustable to accommodate different lengths of file or similar instruments, the lower arms may be adjusted to operate close to table for different lengths of stroke.

The file holder will hold ordinary or round shank files, readily adjusting itself to taper of shank of file or similar tool. When the file is worn in one spot it may be shifted until the whole file is worn on all sides.

The countershaft is attached to base of machine and has a three-step cone, carrying a 1½-inch belt, which gives speeds of 200, 350 or 600 strokes per minute; the drive being controlled by foot treadle. Driving belt on counter shaft is 2 inches.



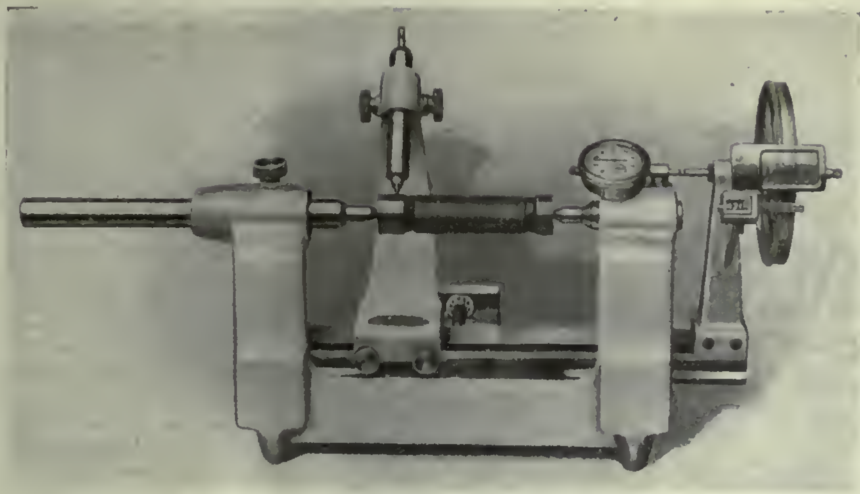
UNIVERSAL FILING MACHINE.

Motor drive can be used if desired. One-half h. p. motor of any type with speed between 1,200 and 1,800 r.p.m. can be used.

HEAD TESTING MACHINE

The "Lea" lead testing machine, sold by C. H. Tracy Co., Boston, has a three-point bearing—two stationary and one adjustable—making it easy and quick to level. The thread contact point and the micrometer head are carried on a ball-bearing carriage, or slide, so delicately adjusted that the operator can blow it back and forth with his breath when the contact point is not engaged. The thread-contact point is held to its work by means of a spring, and it may be moved from one thread to another by pulling it back by means of the small knurled handle shown. The thread gage to be tested is carried between centers. To test the lead the contact point is placed in position in one of the threads and then the micrometer spindle is adjusted so that the pointer on the dial indicator points to zero. The thread-contact point is then moved along one, two or more threads, as the case may be, and the micrometer readings taken and compared to the theoretical amount. Drunken threads are easily detected by turning the gage part way around and again measuring.

In doing the measuring the micrometer



TESTING MACHINE FOR INSPECTING THE PITCH OF SCREW GAUGES.

spindle is adjusted so as to bring the dial indicator pointer again to zero. From this it will be seen that the dial indicator is not used to actually measure with but only to show the correct amount of pressure to apply to the micrometer spindle. It will be noticed that the micrometer sleeve carries a graduated gearwheel while meshed with a pinion attached to a special counter. By the use of the large graduate wheel, readings are obtained to 0.0001 in. As the wheel turns it operates the counter, so that the operator can read his measurements directly and instantly, which greatly adds to the speed with which a gage may be inspected. In using the micrometer no damage is done in case the spindle overruns considerably. When it is not advisable to depend on micrometer readings, Johansson blocks may be used between the dial spindle and the micrometer spindle. A plug is also provided so that the dial indicator may be removed and a solid plug used in place of the indicator spindle. Johansson blocks can then be used between the contact points as before. The machine will test thread gages up to 6 in. in diameter and 6 in. long. It weighs approximately 60 lbs.

PORTABLE RADIAL GRINDING MACHINE

The Mummert Dixon Co., Hanover, Pa., have bought out a portable radial grinding machine. The machine is primarily intended for general light grinding and buffing work, and the wheel can be raised as high as a man can reach or brought down to the floor, in addition to being turned into any position between a plane at right angles to the floor and one parallel with it, as well as having a slight longitudinal movement.

The machine is a self-contained unit and is readily portable. The grinding wheel, which is 8 in. in diameter, with a 1 in. face, is driven by a motor mounted at the rear end of the tubular arm. This motor, which receives its supply of current from an adjacent lighting socket, is coupled to a shaft running through the tubular arm to a set of hardened steel spiral gears in the head. These gears are enclosed in an oil tight gear and increase the speed from 1,800 to 2,800 r.p.m. The head, arm and motor are carried on a two-wheel ball-bearing trolley, which rolls back and forth on a steel track for a distance of 30 inches. A rack and pinion on each side of the carrying frame is relied upon to keep the trolley in alignment. The motor tends to balance the head, and as it is mounted below the center of the trolley shaft, keeps the whole weight in equilibrium when the workman releases his hold. The bolster of the frame carrying the trolley is mounted on the upper end of a trunion which turns in the base. In this way the arm and the grinding head can be turned entirely around the base, thus giving a full radial grinding machine. It is also possible to twist or turn the head completely around so that the top, either side or bottom of a casting can be ground.

When the machine is being moved the trolley can be locked in the middle of the frame, and by inserting a lock pin the bolster can be locked to the base so that it will not turn radially. This arrangement, it is pointed out, will be found advantageous when the machine is being moved over the floor, since the arm can be used as a guide, similar to a waggon tongue.

In addition to the machine illustrated two larger sizes are built. One of these is designed to mount a wheel 14 in. in diameter with 2 in. face, while the other will mount wheels 3 in. wide and either 18 or 20 in. in diameter.

PORTABLE RADIAL GRINDER

BROKEN GAUGE GLASSES

By M. M.

The following hints concerning broken gauge glasses cannot be too forcibly impressed upon engineers. It is not only a matter of knowing how, but also being able to practically apply the knowledge effectively and expeditiously. The cocks on the boiler should be immediately shut and the glass replaced without delay. The new glass should be free from flaws or scratches, with ends ground square or fire-finished and of the correct length. If too long it would restrict the passage of steam to the glass; if too short, the packing may work over the edges of the glass. In many makes of gauges the correct length of the glass is stamped on the framing.

Before replacing it, the whole of the old packing should be removed, and the screws of the adjusting glands made easily workable. The packing should be placed on the glass, and while screwing up the bottom gland the glass should be kept in contact with the metal of the lower cock. Care should be taken not to screw up the upper gland hard before the lower one, as this may lift the glass, and perhaps allow the lower packing to choke the orifice.

The glands should at first be screwed up hand-tight, after which the steam and drain cocks should be opened a small amount to heat the glass gradually, when after a short interval the water cock should be gradually opened, and then the drain cock closed, the steam and water cocks being then fully opened gradually, and the glands adjusted as required. The glass should now be tested by closing the steam cock and opening the drain, when water should rush out freely. The water cock should then be closed and the steam cock opened, when steam should rush out freely. When the drain is closed and the water cock open, careful note should be made of how the water rises in the glass. It should, if the fitting is properly made, rise smartly to the water level of the other glass.

Courtesy Does Not Cost Very Much

IT doesn't cost a very great deal to be courteous. It's the cheapest thing in which a man can invest and yet it pays handsome dividends. An experience that was related to us this week is well worth passing on.

A representative of a big house with branches in nearly all the worth-while cities of the world, had occasion to make two calls in the same city—and that same city was Toronto.

The traveller was a high-priced man, an expert in his line, and he considered it was in the interests of both the firms in question that he should call on them. He was too well versed in his business to take up more time than was absolutely necessary. Here is his experience:

"The first place I called was a firm employing some three hundred people. I asked to see the general manager. My card was taken, and after waiting some time the messenger boy went in again, and came back with the information that the manager was busy. I knew there was no one in his office for I could see in his window before coming into the building in the first place. After another short wait he came out of his office, and I was forced to grab him, book-agent style, to tell him I was around the premises. I could get no hearing at all. He would not even pass me on to his superintendent or purchasing agent. I left and I will never go into that building again, neither will I be particular to look after that man's business if he sends it to me.

"The next call I made was at the other end of the city. There was a little room where callers waited until the manager was able to see them. I seated myself there and within a very short time I had a chance to see the man I wanted. I did not even have to brush past a secretary or ring a bell. That manager came out and shook hands with me and asked me to come in and sit down. I told him the firm I was from and what I wanted to show him. He rang for his superintendent and then said, 'Both the superintendent and I are very busy today, but we will give you 20 minutes right away.' I had not taken up five when the superintendent said he was interested enough to have me come into the factory with him and go into the matter in detail. That satisfied the manager. I closed a nice order there and dropped in to thank the manager after for his courtesy and kindness. That manager controls four times as much business as the first man, and so I take it his time must have been worth much more. He could have turned me down and I know he would have done it in such a way that I would have been satisfied with his decision."

That same thing happens every day in the week. There's nothing so very new in it at all, its newness consisting in the fact that it happens so often.

But get it into you. Get it into your staff. Get it into your men that meet the public. Paste it in their hats and stamp it on the soles of their boots. Courtesy costs nothing at all, but its presence makes and keeps wholesome business conditions, and its absence spoils and mars the whole landscape, and kills off business chances faster than any other power can build them or pull them together.

Trained Hands For Farms and Shops

THE farming community in Canada has been making very serious objections to the taking of green hands hands on the farm.

In many cases they are referred to as useless, and the statement is made that a farmer takes so long in instructing them in the work that they are really a loss in the end.

On the face of it the farmers seem to be able to put up a pretty good case.

But what has been the experience of the manufacturer, of the merchant, of the publisher and of every branch of industrial life since the beginning of the war?

All through it has been a case of do the best you can with the material at hand.

If a publisher were to take the attitude regarding a prospective employee: "You are not experienced. You are not a good journalist of proved worth, therefore I don't want you," what would be the result? There would be so many empty chairs in the office that the publication would never reach the public.

And what of the manufacturer? There has been a scarcity of available men that has been almost overwhelming in spots. Could the manufacturer give instructions to his employment office that they were to say to every applicant for work, "If you are not a skilled mechanic there is no use of you applying here for a job?" Not much. There would be very little production were that the case.

The publisher has had to take the greenhorn and train him. He has had to lose money and time on him for weeks before he was able to earn his salt, and a good many times he found out that after weeks of attempted training he had picked a lemon.

The manufacturer has had in many cases to conduct very costly experiments to find out how far he could go in employing unskilled men in his shop. There have been breaks and annoyances without end, but the manufacturer had to make the best of it, and "carry on," and like the publisher he has accepted the situation as it stood and made the best of it.

Why should the farmer not look at the thing in the same way? He cannot have trained help when it is denied to the rest of the community. There are cases where greenhorns to farm work are making good as they have done in other lines. It takes no greater skill to drive a binder than it does to run a lathe, and the wielding of a hoe is no more complicated than the writing of a heavy editorial.

The farmer can get a whole lot of service out of the greenhorn help if he will set himself seriously to it.

A NUMBER of the daily papers are howling away that Canada's assortment of Cabinet Ministers should hustle back home from London, England, and attend to affairs at Ottawa. Then again there's not a few who incline to the belief that we get along remarkably well when the whole outfit's a long way from home.

IT USED to be considered a bit smart to refer to the farmer as a hayseed, but when one stops to think that farmers lead the automobile procession, and are the leading group in paying off mortgages—well, it all tends to popularize the hayseed group.

ANDREW GLEN CAME FROM SCOTLAND IN 1912

And Has Been Manager of the John T. Hepburn Plant for Two Years—A Want Ad. Brought the Right Man

IF your father's name is trusted to one or two initials for what individuality it had—if his name was Smith, Brown or Jones, for instance—no fair body could blame you for secretly wishing you could swap names with Andrew Glen. His name is more than likeable; it is Scotch both going and coming. So is he.

Fifteen years ago, as a lad of sixteen, he started work in the plant of Lees Anderson, which is on the Clyde at Glasgow. Had young Glen been a few years older, or had no business depression followed the Boer war, Lees Anderson, makers of marine engines, might be on the high-tide of prosperity to-day. As it happened, however, they carried on until the subject of this sketch learned all their drawing office could teach in two and a half years.

ANDREW GLEN

The last pulley had hardly stopped in the Lees Anderson plant before young Glen was applying what he had learned—and learning more—in the plant of Alexander Chaplin & Company—one of the largest crane makers in Glasgow. Another two and a half years at the pay of an apprentice, and he graduated as a full-fledged mechanical draftsman.

But Andrew Glen had not been content to work and learn. He had wanted to study and learn as well. During the years of his apprenticeship, therefore—years with more nine-hour working days than many men, let alone youths, care to manhandle—he studied at nights. Three evenings a week he attended technical college. Nor did he reach it by walking across the street. It was six miles from his home.

About the time that Babcox & Wilcox of Renfrew, which is near Glasgow, discovered that a good man like Glen, either goes up or goes out, John T. Hepburn, of John T. Hepburn, Limited, Toronto, concluded that the Old World owed the New the man he needed. And he used the New World method to find him—that is to say, he advertised.

Glen answered his advertisement, interviewed Mr. Hepburn's brother-in-law and, two weeks later, took charge of the drawing office of John T. Hepburn, Limited. This was in the year 1912. If questioned to-day, Mr. Hepburn would probably say no advertisement of his ever paid better than the small help wanted that found Andrew Glen.

The young man soon demonstrated that he knew a thing or two about cranes. (John T. Hepburn, Limited, manufactured cranes exclusively up till the outbreak of hostilities). Moreover, Glen showed rather unusual ability in directing work to speedy accomplishment as well as in the perfect planning of it. Consequently, within two years following his engagement, he was made manager.

Almost simultaneously with his appointment, the urgent needs of war called for a radical change in product. The manufacture of cranes could wait; the manufacture of shells and shell-making machines could not. Glen's was a man-size job all right!

How did he handle it? The well-known Hepburn special lathe for munition makers is one favorable answer. Another is the fact that John T. Hepburn, Limited, recently acquired the plant of the Martin Pump & Machine Company, in which forty men are already employed and which will produce at least, three Hepburn special lathes daily. A third, and equally significant answer, is the fact that two hundred and fifty men are employed at the parent plant, now manufacturing six-inch shells as well as special shell lathes. A fourth—is a fourth needed? No. Just consider that Andrew Glen has yet to count his thirty-second birthday.

"It isn't the salary cushion of an executive's chair—it isn't that," he said, "that drives a man to study and work his way into it. I think it is our competitive system, the pitting of men against men. The failure is all eyes for the immediate dollar. Not so the man who wins. He keeps half an eye on the dollar and an eye and a half on his work and on the textbooks and technical magazines that help him master it."

Young machinists need not conclude that an hour or two of serious study after work will prevent their enjoying healthful recreation. Andrew Glen snatched time to play association football and to win more than one road race. ten-mile marathons included. He has his medals still.

His life mirrors ability to do the things worth doing. True, he confessed, "I've never had time to get married."

But there's time yet—he's only thirty-one.

An Appetite's A Bad Thing Now

THIS cost of living is a thing what causes me to fret—I'm worried in the day time, and at night I can't forget. Why everything folks get to eat is priced so bloomin' high, that a purse would need, by gum, to reach well nigh unto the sky.

We used to buy the sausage cheap, about ten cents a yard, a nickel for a T-bone steak, and 'bout the same for lard.

And liver, too; land sakes alive, they used to get it free—it used to cost ten cents for lunch and less'n that for tea. And look at spuds, the Irish kind, the onions and the beets, and every other thing that comes in servin' up the eats.

And if you want a dozen eggs, the big ones and the slim, it costs you over half a bone, why say, they don't begin to touch the good old buying times, now gone a long time hence, when hen fruit used to sell galore at twelve and thirteen cents.

When we was kids we used to take a quarter to the store, and have a list a foot in length of what we hustled for.

And for that coin we used to get some butter and some ham, some eggs and rice, a pound of tea, and salmon in a can. We used to stack up all these things upon the kitchen range—and dig deep in our jeans to land the coin we got in change.

We passed up ham and bacon, too, and roasts of every sort, to try and keep our carcasses from wanderin' into court. And ground up steak has got the boots, rump roasts have gone likewise—we never get a hunk of ham, nor dig in on meat pies.

It is a sad, a lonely world, there's just one thing, by heck—we sometimes buy a slab of chuck what's carved from off the neck.—ARK.

MARKET DEVELOPMENTS

Final Allotment Made by Ottawa War Board

Dealers Who Are Trying to Handle the Business Finding it Harder to Secure Actual Supplies Than the Permits Covering Them—More U.S. Contracts Going to be Given Out?

DEALERS in Canada who are trying to spread around the available supply of steel, among the many firms that present orders for same, are having troubles of their own during these months. It would appear that the procedure is this way: The authorities at Washington, through the war board there, give a certain proportion of the output of U.S. mills to Canada every month. It is then up to the War Board at Ottawa to distribute this supply. This really means that the War Board at Ottawa has got to take on itself the onus of stating which firms in Canada shall have a preference on available supply of material, and the agricultural and other interests are not going to stand aside while the distribution is taking place unless they are being favorably considered in it.

Although nothing definite has been given out yet, it would not be surprising were an announcement to appear in the near future that the American war contracts in this country were to be considerably enlarged. Rumors from some of the steel centres in the U.S. which are very reliable, state that new sizes are being considered there and also draw attention to the fact that a very much increased autput of shell steel is asked for in the next few months. Canadian firms have made an enviable reputation for themselves by the way in which they have handled U.S. business on previous occasions. No doubt they would be favorably considered in any extension to the war program of the republic.

Although reports have not indicated it, the labor situation is causing some trouble in certain localities. One place where it shows very plainly is in regard to the scrap metal situation. Reports from a large number of the big centres in the U.S. state that the labor shortage is causing some delay not only in the bringing in of material in the first place but also in the sorting after it reaches the yards. In this way it is retarded from a quick move to the foundries, where it is very much needed at the present time.

Agents in this country who are handling British high speed steel believe that an effort may be made by the firms in the Old Country to get better shipping facilities to this land. In the last few months there has been a tremendous demand for high speed steel by almost every factory handling war orders in Canada, and U.S. firms have cut into his business to a very great extent. And in order to protect their interests here, British firms are likely to make a very determined effort to get their goods into the Canadian market as quickly as possible. Shipping facilities have worked against them in this regard in the past in no uncertain way.

Prices, as a general thing, have been holding remarkably firm during the week. As a matter of fact the whole range of prices has shown very little tendency to change. Reports to-day indicate that galvanized sheets are likely to go up. The mills cannot secure the black sheets for galvanizing, and the chances are that as a result all light gauges of sheets will go up. Apart from this no price changes or indication of changes are reported during this week.

FINDING IT HARDER TO DRAW NOW FROM UNITED STATES SOURCES

Special to CANADIAN MACHINERY

MONTREAL, Que., Aug. 7, 1918.—Despite the fact that the present period is generally one affecting trade conditions, the activities at the present time are almost normal in character. Production has fallen off slightly but not sufficient to affect the general conditions. The steel situation has developed an acute turn owing to the inability to get material in from the American mills. The metal market is operating under considerable tension due to the scarcity of some of the metals. Old materials are quiet with dealers reporting a nervous undertone.

Tension in Steel Situation

The continued demand for steel, coupled with the decline in production, as a result of the warm weather, has maintained the tension that has marked this situation during the past several months. That this condition may be still further emphasized is shown by the increased difficulty in obtaining ship plates from the States. Trade in steel plates has virtually been taken out of the hands of the War Trade Board as the mills in the States are unable to meet the present abnormal trade requirements. Plates for ships under Government contract are coming through but with less regularity than formerly and shipyards are consequently working at a disadvantage. Unless plates are specifically required for essential uses no consideration whatever will be given to orders placed for material. Local supply of steel plates is rapidly being depleted an dthe situation is taking on a very acute turn. Shell steel is coming along in fairly good volume, but the output has been interferred with by the holiday season, and labor shortage. Foundries are active producing billets for the recent contracts for 9.2 inch, 155 m.m., and shrapnel shell forgings. In the semi-finished steel trade the sifting out of so-called non-essential activities has added to the difficulties of obtaining material for enterprises indirectly associated with war work. The market here, if such it may be termed, is relatively quiet and all quotations are firm, but virtually on a nominal basis.

Metals

The feature of the week appears to be the difficulty experienced by dealers in obtaining metal to meet their immediate requirements. Tin continues to be the center of interest and the developments in London have had the tendency to strengthen the market here. Copper is hard to obtain and the situation is very firm. Lead is showing a tendency to advance owing to scarcity. Spelter is weaker on quiet demand. Antimony and aluminum are both quiet, but comparatively firm.

Copper.—The difficulty in obtaining supplies of copper from the United States refineries has placed the dealers here in a very uncertain position, and the general situation is one of extreme nervousness. Local stocks are declining and the undertone is noe likely to develop into a stronger market. Agitation for further price regulation continues to keep the trade in tensive mood. Dealers here report a rising market, quotations at 31 and 32 cents being an advance of ½ cent over last week.

Tin.—The situation in this metal is again developing a very acute stage owing to the inability to acquire sufficient tin to meet the requirements of essential needs. The uncertainty of delivery from England and other sources gives the market a nervous tone, and with local stocks gradually falling off prices here have advanced to the previous high. Dealers for some few weeks past have been quoting the nominal price of $1.10 per pound, but this week have again advanced to $1.25.

Lead.—Dealers are having some trouble supplying the demands of customers owing to the apparent scarcity of the metal. The present requirements are relatively heavy and stocks here are light. The market is very firm at 10½ cents, but the tendency is upwards.

Machinery Demand Slackening

Afalling off in the general demand for machine tools marks the developments for the week. Shell machinery is not quite so active but this is to be expected, as most of the plants recently receiving renewal or new contracts have placed their equipment orders. The chief concern of both dealer and manufacturer is getting the delivery of the different tools required. Shipment of equipment coming in from the states is very indefinite and the delays are causing considerable inconvenience to the producing trade. Partly used machinery is selling well, and this equipment can be secured more easily than new tools owing to the fact that second-hand machinery is not controlled by tre same selling regulations. Trading in this respect is comparatively heavy and tools are quite plentiful.

General machine shop supplies and accessories continue very active and the market is very firm.

Nervousness in Scrap

Apart from the nervous tone created here over the report that copper scraps would shortly weaken and prices decline, the situation is comparatively unchanged. The general demand has quieted down and buying is almost exclusively for consumers immediate requirements. The marked uncertainty has developed a reluctancy on the part of consumers and trade on all metals has become restricted. Quotations are firm with an unsteady undertone.

POINTS IN WEEK'S MARKETING NOTES

Reports from the big scrap metal centres make it appear certain that a shortage of labor is causing considerable delay in sorting scraps and getting it out to the consumers.

—

In every case now dealers who are getting a supply of pig iron are tied up on government contracts so that it is impossible for them to use any material for any other purpose.

—

Steel jobbers in Canada are finding it more difficult to secure their supplies from Ottawa. It appears that a certain allotment is made at Washington, to Canadian consumers, and it is up to Ottawa to distribute that.

—

A request came in to the American market this week for the supplying of a large number of machine tools to manufacture bayonets. This is about the first time that this work has been taken up.

—

Pittsburg reports to this paper that it is a much easier matter to secure a license from the War Board there than it is to secure the material itself after getting the license. The supply of steel is far short of the distribution for which the license provides.

—

Reports are in circulation that the shell programme of the United States is to be greatly extended. Some details have been given out, but on the whole information is lacking as to the number and size of shells to be brought out in the next few weeks or months.

—

Absolutely no information at all is being given out by the authorities in regard to the building of the greatest ordnance factory in the world at Neville Island. It is stated that the first guns will be turned out from there the beginning of 1920. As a matter of fact this date will be hastened by a good many months.

HARDER TO KEEP ORDER BOOKS CLEAR

Washington Gives Lump Portion to Canada, to be Divided by Ottawa War Board

TORONTO.—The steel jobbers are finding it harder to fill the orders that are pouring in on them, and they are going to find it harder later on. There is no end of orders, and as may be supposed every firm sending in an order is quite sure that his work is of the utmost importance toward the winning of the war and should beb shoved right through Washington and Ottawa and any other centre that has to do with the granting of the license. Washington, in allocating the output of American mills, lumps the portion that shall go to the Canadian users, and tosses that over to the War Board at Ottawa, and it is then up to that body to go ahead and worry with the Canadian consumers, trying to keep the strictly war business concerns to the front. The further this system is put into effect the more trouble there is bound to be, and the harder the work that will fall to the lot of the War Board at Ottawa.

Prices have shown no great tendency to change during the week. The holiday at the week-end has eased matters up a little, although in some cases there are tendencies that prices will move along again soon. From the way matters are moving it looks as though galvanized sheets were due for a higher level. The mills are finding it harder to secure a supply of the black sheets to galvanize. In fact all the light gauges of sheets are liable to go to higher levels before many days.

There is no improvement in the boiler tube situation especially as it affects the smaller sizes. There is a fair amount of the larger sizes left, but the big demand just now is for the size around two inches.

Scrap Metal Situation

Prices that have been quoted by the dealers during the last week will continue to govern the dealing during the next week or so unless something very unusual turns up. There is always a period of price stagnation around this time of the year, and the only thing that has turned up to interfere with it recently was the trend of copper and brass upwards following the action of the U. S. government in raising the fixed price on copper.

As a matter of fact there is a good deal of scrap passing just now that the dealers are not touching in the transaction. One of the largest dealers in this district stated to-day there were many of the mills with a good supply of heavy melting scrap on hand, and he did not know where it had been secured. There is only a fair volume of business moving. Scrap is not being located easily, and in many cases those who secure it in the first place are forced to go farther afield for it than formerly, and in this way they want more for their work. The labor problem not only in the scrap yards but in the premises of some of the big scrap sources keeps a lot from the market. There is not the help available to properly sort the material, and so it is held back.

No definite word has been given out regarding the disposal of the electric line from London that is passing into the hands of the scrap merchants. There is quite a bit of interest locally in the deal and it is known that several of the dealers have made a number of trips to London to look the proposition over. It ought to be definitely known in the next few days what will be done. Foundries continue to inquire for good machine scrap to ease off on their piles of pig, especially if they are not in a line that will be guaranteed a supply by the War Boa.d at Ottawa.

THOSE WHO GET PIG IRON ARE TIED TIGHT TO THE GOVERNMENT

Reports received from the various producing points in United States on the pig iron situation are as follows:"

Philadelphia.—Small lots from the Virginia makers are being sold to some of the foundry iron buyers here. Only two cars per customer are now being distributed and sales are being made only after receiving declarations of purpose from the consumers. Delivery will be made after all priority and allocated orders have been shipped.

Boston.—Some Virginia iron has been arriving here in the last few days but none of it has ever come into the open market as it has all been directed to consumers' destinations. These customers are on the preferential list and were tied up forty different ways by the Government and only one or two cars for each customer were received. Good progress is being made on onld contracts.

Pittsburgh.—Inquiries for both steel making and foundry iron continue to come forward here in very large volumes but the producers generally continue to withhold making any promises. Rather a new feature here is that many of the producers consider that it would be good policy on their part to make contracts on three months' terms, claiming that that is the period for which the Government regulates the prices.

New York.—Some of the Alabama furnaces have been taking considerable orders here for future deliveries and some of the foundrymen may have thought they were in for fairly good supplies. Later orders, however, have it that instructions from the producers to the agents were to cut down on these orders so they were reduced very materially. All of the iron thus sold was without any guarantee of any kind and delivery is to be made only after all the Government orders are filled.

Buffalo.—There is an inclination here among the furnace men to leave the distributing of their future products to the authorities at Washington as they apparently reckon that the Government people will get it sooner or later. In one case a furnace man here took on 1919 business during the last week but that was from an old customer whose plant is working 100 per cent. on Government orders, and he desired simply to be covered as a matter of preference.

Cleveland.—The demand here for pig iron continues to be very, very heavy and most of the consumers are able to show without any doubt that any iron consigned to them will be used for essential purposes and on this account shipments are going forward quite freely. The call now for iron for steel purposes is simply tremendous and it is thought here that a number of the furnaces that are now turning out pig iron will be ordered in the very near future to switch over to the basing material before the month is finished.

Cincinnati.—It appears almost certain now that the stove makers here will have to curtail their product to a considerable extent as only a few of them have been able to make contracts for iron. The word has been pased along that only those that have contracts calling for the supplying of towns for army purposes will be able to get all the iron they need an dthe others will have a hard time in getting metal that is to be used in the non-essential work.

St. Louis.—The war plants in this district are practically getting all the pig iron they require at the present time. Stove makers and others who turn out specialized lines are feeling the pig iron shortage and in many cases they have been resorting to the use of an unusually heavy tonnage of scrap.

Birmingham, Ala.—The belief is expressed in some quarters here that those who have been anticipating an increase in production of pig iron are going to be disappointed. Inquiries are coming in very rapidly and it would be a very easy matter to sell the entire product for 1919.

WANT TOOLS FOR MAKING BAYONETS

Unusual Demand Made For a Large Quantity of War Machinery

Special to CANADIAN MACHINERY.

NEW YORK, Aug. 7.—Gun makers are the largest purchasers of machinery in the market at present and several large contracts, calling for the expenditure of \$5,000.000 to \$6,000,000, are still before manufacturers; at the same time, new inquiries for machine tools have fallen off in the past ten days, which is accounted for by the recent Government decree, practically establishing a barred industrial zone on the middle Atlantic seaboard and in New England.

As various factories in the middle West are converted into munition plants there is naturally an increase in the placing of many small orders for metal working machinery. Dealers and distributors of tools in Chicago have benefited largely from this business, working at very high pressure. The volume of business has been made up, however, of numerous small sales rather than of individual large lists. At Cincinnati and Cleveland there has been a falling off in large inquiries as well as in New York and in Philadelphia.

For Making Bayonets

An interesting development has been the active demand for the lighter types of milling machines. This phase of the situation has been brought out by manufacturers in Milwaukee, who, within the last week have received telegraphic inquiry from an Eastern manufacturer of bayonets for 62 light milling machines. This is the largest inquiry for such light tools that has ever come before the Milwaukee trade, but as the Government is now placing large orders for munitions in the Central West, this demand is likely to increase rather than otherwise.

Still in Millions

The Midvale Steel and Ordnance inquiry for 300 to 400 machine tools and for 104 cranes to be installed in the sixteen-inch howitzer plant at Nicetown and calling for an expenditure of about \$2,000,000, are still before the trade. Negotiations also continue on about \$3,000,000 worth of cranes for the Neville Island Ordnance plant that is being built by the United States Steel Corp. Plans for these works, while not completed, have progressed sufficiently to make it certain that the American Bridge Co. will be called upon to fabricate 150,000 tons of structural steel for the various buildings to be constructed in the next eighteen months. As a result, the American Bridge Co. has been compelled to refuse several large Government orders calling for about 30,000 tons of steel for the construction of nitrate plants and other military buildings.

Marine Shapes

The pressing demand for the fabrication of steel for shhipbuilding has caused the American Bridge Co. to devote, temporarily, its Trenton, New Jersey, shop, entirely to the fabrication of marine shapes. These plans have caused the suspension of the steel barge building at Trenton for which the shops were especially equipped about three years ago. The Bridge Co. is fabricating steel at Trenton for fifty ships, 30 of which are being constructed by the Merchant Shipbuilding Corp. Bristol, Pa., and 20 by the Federal Shipbuilding Co. at Kearny, New Jersey. Incidentally, the Federal Co., which has just ordered two more cranes, expects [illegible] its second 9,600-ton boat for the Government about Aug. 10th.

The Newport News Shipbuilding &

Drydock Co. has put out a revised list of 15 cranes for its marine boiler plant at Richmond, Va. The Bethlehem Shipbuilding Corp. has come into the market for six additional special cranes for its Alameda, California, works. Purchases of 34 cranes for marine boiler shops are being made by the Sun Shipbuilding Co., Chester, Pa., and by the Barber Asphalt Paving Co., the latter for its Iroquois works at Buffalo.

MUCH EASIER TO SECURE LICENSE THAN THE GOODS TO FILL THE ORDER

Special to CANADIAN MACHINERY.

PITTSBURG, Pa., Aug. 7.—There was a time when it was difficult to secure export licenses. The much stricter measure of steel control by the War Industries Board has made it easier to secure the licenses, but of course it is more difficult to secure steel. In other words, steel shipments are so difficult to secure that once the War Industries Board permits any steel to be shipped the War Trade Board does not see that it has occasion, as a rule, to demur at granting the export license. In the case of Canada, requests for licenses are made to the Canadian authorities, who in turn apply to the War Trade Board at Washington.

New regulations issued from time to time relating to the distribution of steel cause more or less confusion for a while, but they soon come to be well understood and the mills find it easy to follow the regulations, so far as the regulations are concerned. Their difficulty is in the fact that the supply of steel is far short of the distribution for which the regulations provide. Time after time the steel industry has looked forward to a surplus of steel, or at least to a condition when the quantity required would not exceed the supply, and repeatedly it has been disappointed. The relations between requirements and supply have been growing tenser even in the past week or two and mills have now given up any expectations that steel will become relatively plentiful.

Expanding War Program

The shell program has been greatly extended. Some details have been given out, but on the whole, information is lacking as to the number and size of shells to be handled in the next few weeks or months. What is definitely known by the steel trade is that it is called upon to furnish much more shell steel than formerly. One estimate is that in place of 425,000 tons a month lately furnished there is to be provided 500.000 tons a month for the remainder of the year. These figures are probably below the mark rather than above.

The extent to which consumption of steel in shipbuilding is expected to grow is clearly brought out by the fact that there is now accumulated something like a million tons of steel at shipyards and the fabricating plants serving them, but C. M. Schwab, Director General of Shipbuilding, wants to increase this stock, and is calling upon the plate mills to make stronger efforts. It is plain that if with rate of shipping in the past few months a million ton stock could be accumulated in so short a time, the rate of shipping was far in excess of the rate of consumption, hence if heavier shipments are desired it means that the rate of consumption is expected to increase very greatly. This can readily be understood, for the shipways now in operation should work more and more rapidly as time passes and there are many shipways still to be completed. It is a curious thing that there is no official information, in anything like complete form, of the number of steel shipways completed and to be completed. Fragmentary information on the subject makes it clear that the number in actual operation at present will be largely augmented.

Greatest in World

As is well known, the greatest ordnance factory in the world is being built on Neville Island, in the Ohio river, a few miles below Pittsburgh, through the formation of a partnership between the United States Government and the United States Steel Corporation. The partnership contract is a remarkably brief one. The Steel Corporation supplies the organization and engineering services, gratis, also the blast furnace, already existing and the steel-making department it will build, these to remain the property of the corporation. The Government supplies all the money for building the ordnance factory proper, and will own it. The main offices of the "U. S. Steel Corporation Ordnance Department" are located in the building in which this report is written. Despite the magnitude of this undertaking and the great public interest there is in it, there is absolutely no information given out for publication. When the announcement was first made in Washington it was intimated that the plant would turn out its first big guns early in 1920. The statement is rather amusing, as it merely represents the War Department profiting by its experience in connection with the aircraft program, which was set for a little bit too short a time, hence much criticism when it was not carried out. The guns will undoubtedly be in actual service before the beginning of 1920. Illustrative of the lack of information on the subject, one of the Pittsburgh daily papers prints a statement that the contract for the "grading and foundations" has been let, amounting to $5,000,000 or $6,000,000, which is quite absurd, for Neville Island requires no grading and the cost of foundations is necessarily only a small fraction of the cost of the buildings and machinery they will support. Equally out of line is a statement published in all seriousness that the American Bridge Company will be called upon to fabricate 150,000 tons of steel for the buildings during the next 18 months, while the total fabricated steel will be 200,000 or 250,000 tons. Either the time mentioned is altogether too long; or there is included a large amount of fabricating for gun carriages, etc., as the plant operates. One thing, however, is well known. The plant will specialize upon very large guns, particularly 14-inch and larger, with their ammunition, and its operation will not interfere in any way with the regular shell program as being expanded from time to time.

Steel for Jobbers

The War Industries Board's regulations dated July 2, relating to supplies of steel for jobbers during August, have been received in various moods by the steel mills. The general program, previously formulated, is for jobbers to confine their shipments to the purposes on the preference list, report the shipments by month. A special arrangement has been made for August, however. This is that the mills ship jobbers during August an amount of steel equal to the average monthly shipments in the first half of this year. The replacement steel was given Priority B-4 and it is assumed that the August shipments are to be regarded as having the same priority. Some mills point out that they could not ship in August without having scheduled the material weeks before. Others observe that they have so many higher priorities that they could ship very little material against a B-4. Others explain that they have no specifications from jobbers on which they would venture to ship, expecting the material to be what the jobbers most need. They have specifications filed last November, and the jobber, given the privilege of receiving a certain tonnage of steel, might want an entirely different description now. Other mills say they have studied the regulations and expect to experience no difficulty in carrying them out. It is partly a matter of temperament and partly a difference in the position of different mills.

Production

Production continues very satisfactory indeed, considering the conditions. In every previous year there has been a sharp curtailment in July and August, due to the heat. This year the industry has run through more than half the period and is, in substance, maintaining the excellent rate shown in June.

SHELL CASE BLEW TOY OFF FURNACE

The Unlucky Number 13 Was The Number That Contained Live Matter

The Judson Iron Works, Oakland, Cal., received a carload of scrap from Arizona last week which nearly wrecked the plant. The load included a number of 3-in. and 5-in. shell cases, and some of them proved to be still loaded. The explosion of one of these shells in a furnace blew off the top of the furnace and narrowly missed doing some very serious damage. Investigation revealed 25 such shell cases in the shipment, 13 of which were loaded.

SHORTAGE OF LABOR MAKES IT HARD TO SECURE SCRAP NOW

In connection with the scrap metal situation in many of the large points in the United States it would appear that the labor shortage is one of the biggest factors interfering with the sorting and securing of supply for the foundrymen. Reports from the various centres are as follows:—

New York.—A great many of the larger yards here have been forced to curtail operations on account of the labor shortage. Cast scrap remains in particularly heavy demand with the bulk of this material going to local foundries. Reflecting the continued sharp demand for cast scrap are the higher prices now being paid for stove plates and grate bars.

Boston.—There is a large volume of trade moving but labor is holding back a good number of the contracts and causing some serious delay in the filling of them. It is a safe estimate to say that in some weeks the yards are unable to handle any more than 50 per cent. of their work, while at the outside 60 per cent. efficiency has been about the normal figure during this sommer.

Philadelphia.—Small lot trading seems to characterize the scrap situation here, as it seems to be very, very difficult to locate any large tonnages. Borings and turnings are being eagerly sought by blast furnaces to increase their output of pig iron and reduce the coke consumption. The labor situation is also a very acute one here, although in some cases it is pointed out that the yards that are having trouble in securing men are the yards where they are not paying sufficient wages. Several reports have been circulated here to the effect that the Government intends to commandeer all the available scrap, but this report is denied almost as quickly as it is put in circulation.

Pittsburgh.—The stocks of scrap in the yards of dealers here are reported to be very low and in some cases entirely exhausted. Large orders are not coming into the yards here at all, as it is explained in many cases all the scrap is being used in the district where it originates.

Buffalo.—The opinion of many of the large scrap dealers here is that the labor problem is the biggest thing they have to go up against at the present time. Not only are the yards handicapped by the lack of men but the consumers say that they have not sufficient help to handle the scrap when it comes to them. Many of the dealers are not able to classify and sort the stock as it comes to them and because of this they are not able to pass it on quickly to the trade. In fact some tonnages of scrap have been refused in this locality lately because there is not the labor supply to deal with them.

Cleveland.—Heavy melting melting steel is in particularly heavy demand here just now but the supply is no better than before. There appears to be a very large stock in the yards of some of the dealers but is of a miscellaneous character and requires a very great deal of handling and sorting of a more or less skilful character before it can be placed on the market. Some of the dealers say that with a new 25 per cent. increase in freight rates they are losing money on contracts that were figured on a rather narrow margin.

St. Louis.—One thing that is very noticeable in the scrap supply situation here is that railroad offerings are becoming very scarce. In fact in some cases they have almost reached the point. This week there were hardly any lists at all from the transportation companies and it is not likely that any will be sent out in the near future. Since the Government took control of the railways there is a tendency as a matter of policy on their part to sell all scrap direct to the consumers, and dealers claim that in this way they are being eliminated from the transaction. Reports from American points would also seem to indicate that there is a very acute situation in the sheet steel markets. Many of the salesmanagers for the large concerns know quite well that the jobbers are in dire need of all grades of sheets. The jobbers are lo wbecause supplies to them have been curtailed very materially during the last 60 days.

Other reports claim that in the Pittsburgh district the mills are showing a further decrease in sheets. It is estimated there that the output does not exceed 55 per cent. of the capacity.

Report from Chicago claims that the extreme heat during the past fortnight has had some effect in reducing the output of the sheet mills.

GAS MASKS

GOVERNMENT experts of all countries are constantly trying to develop means of protection against poisonous gases, against which the men have to battle daily. Masks of all types are used continually in most attacks. Our photo shows the masks now used by our Allies and the enemy. From left to right they are: American, British, French and German masks.

New Works of Westinghouse at Philadelphia

The New South Philadelphia Plant of This Company Was Put Up in Record Time—A Little Over a Year Ago the Present Site Was a Plowed Field

SPURRED on by the need for ships, the Westinghouse Electric and Manufacturing Company has made a record in the erection and operation of its South Philadelphia works, now devoted entirely to the production of ship propulsion machinery for the navy and merchant fleet. A little over a year ago the present site was a plowed field; now it contains seven large buildings which give employment to 2,500 people. These buildings, comprising a floor space of over 600,000 square feet, include a pattern storage shop, foundry, forge shop, power house, erecting shop, and two machine shops.

The location is Essington, or South Philadelphia, about nine miles from Philadelphia on the banks of the Delaware River. Two steam railroads, an electric line and the river afford means of transportation, though the last mentioned has not as yet been utilized.

The greatly increased demands on the Westinghouse Electric and Manufacturing Company for steam-electric generating units, led to the necessity of seeking enlarged facilities, as those at East Pittsburgh were already crowded, and the South Philadelphia site, embracing 500 acres, was chosen as possessing more desirable qualifications than any other considered.

It is expected that eventually this plant will be of a size comparable with the East Pittsburgh works, which now employ in the neighborhood of 25,000 people, and cover a floor space of over 100 acres.

A portion of the land will be devoted to a town site capable of accommodating about 5,000 people, though as yet no housing has been erected in deference to the desire of the government that all building activities be restricted to those closely related to the production of materials needed in the prosecution of the war.

An interesting feature is the use of standard gauge trucks through the yards and buildings so that all transportation whether railway or interworks, is carried on the same tracks, and maintenance of tracks and equipment of different gauges is avoided.

Electric energy for operation of the works is obtained in the summer months from the Philadelphia Electric Company at 66,000 volts, and through the steam turbines in the company's plant in the winter months, when the exhaust steam is used to heat the buildings. Distribution of current is made throughout the

EXTERIOR VIEW OF FOUNDRY.

WESTINGHOUSE ERECTING SHOP.

grounds at 6,600 volts by means of lead covered cables laid underground to substations located in the various buildings. Here it is changed to the current of the proper kind or character for the work to be performed.

Compressed air for manufacturing purposes is obtained from synchronous motor-driven air compressors located in the substations.

Water for all purposes except drinking and cooking is obtained from the Delaware River through an open canal, which terminates in a reinforced concrete box on the testing floor in the erecting shop, where an adequate supply of water is required for testing purposes.

A similar and parallel canal acts as an outlet and storm sewer, the entire installation having been designed to take care of anticipated plant development.

An unusually elaborate sewage disposal plant, embodying the Imhoff system with lime as a precipitant, has been installed.

The selection of the site and the general direction of all the activities incident to the erection and operation of the plant have been in charge of Mr. H. T. Herr, vice-president, who has had as his assistant, Mr. R. B. Mildon, who has had general supervision of the construction of the plant.

The plant has been erected by Westinghouse, Church, Kerr & Company, with which firm, Mr. Calvert Townley, assistant to president, has handled all business relations, subject to the approval of the president, Mr. E. M. Herr.

WORKING WITH OR AGAINST THE OTHER SHIFT

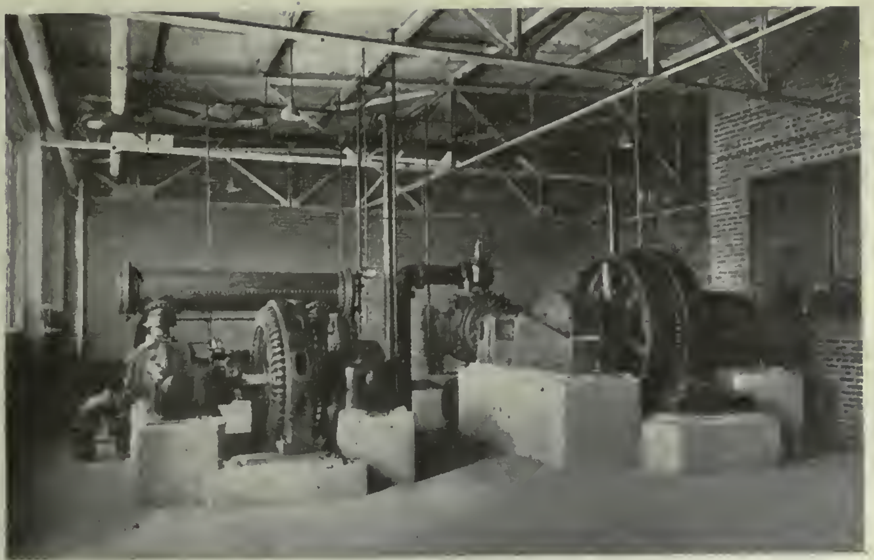
By J. H. Rodgers.

Factory harmony may frequently prove to be a very important factor in determining the resultant efficiency of any industrial plant. This not only applies to the smoothness and regularity in which the work progresses through the sequence of the many detail operations, but to the conscientious co-ordination of the different parties involved in the achievement of the results desired. Apart from what has been attained by the adoption of automatic, semi-automatic, and special purpose machines for increasing and maintaining production at maximum figures, the human element still remains the foundation upon which the structure stands or falls. From the head executive to the small errand boy, every intermediate employee is responsible for the performance of certain duties upon which depends the success or failure of the enterprise. Weakness in any structure must inevitably mean its partial or total collapse. To repair this defective for serious results are effected is not only a necessity, but it is equally essential that the cause of the trouble should be located, and steps taken if possible to prevent an occurrence of the trouble.

STORAGE BATTERY TRUCK FOR INTER-SHOP AND YARD WORK.

In many manufacturing establishments, production is often affected by the petty dislikes or grievances of some of the workmen or foremen, or the lack of co-operation between different departments, in which interharmony and mutual understanding is of vital importance, when considering plant efficiency as a whole. It may often happen that individual inefficiency can be traced to a certain workman—at least as far as outward appearances prove—but upon

INTERIOR VIEW OF MACHINE SHOP.



INTERIOR OF SUBSTATION, WESTINGHOUSE PLANT.

closer investigation it may be learned that others are indirectly involved for the unsatisfactory achievement.

The Way to Success

Nowhere is close co-operation more urgently required than in those factories where progressive operations are carried on in the manufacture of this product. This applies particularly to the shell making industry as an outstanding example of production on a highly standardized basis. In the majority of munition plants the character of the work and the quantity produced requires the installation of equipment that will virtually meet the predetermined requirements. These expectations are invariably based on the supposition that the workmen employed will continue to operate their machines with comparative regularity to avoid unnecessary disorganization in the routing of the work.

Needless Squabbling

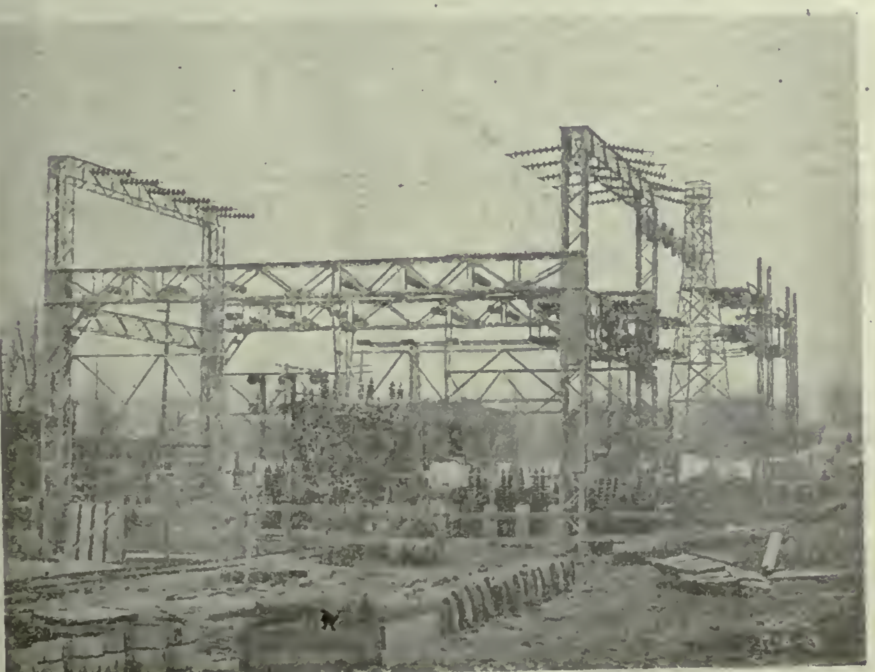
Mutual misunderstanding or petty differences may lead to conditions that cannot but reflect on the progress of the work, and consequently the ultimate output. The writer, on several occasions, has listened to—and been inwardly amused at—somewhat heated harangues between two employees on adjacent machines as to the careless manner of the former in getting rid of the shells after his own work had been accomplished. Some men are so selfishly inclined that little or no consideration is given to anyone or anything, unless they can directly benefit. In one of the instances just referred to it appeared a particular delight for the first man to place his mate—on the succeeding operation—to the extreme inconvenience in picking up the shell for his particular operation.

A Friendly Spirit

A feature that seems to have received little attention is the possibilities that might be derived by developing a more friendly spirit among the men, particularly between those men that are called upon to operate the same machine on the different shifts. In many instances these two men never see each other, and where two workmen with widely different characteristics are operating the same machine—one by day and the other at night—it is quite reasonable to expect that perfect harmony cannot exist between the two unless some kind of mutual understanding exists between them, and which can only be acquired by personal contact. I have spoken to men who have told me that it was sometimes an hour before they got going owing to the inability to locate the tools and put the same in condition to his own particular taste. Asking one of these as to the care he exercised in leaving the machine and tools in good condition for the night hand, he replied, "Why should I worry, I have to look out for myself when I come in in the morning, why shouldn't he?"

To illustrate what might be done in this direction, I might cite an instance where the peak of efficiency was attained in machine tool operation. It was in connection with shell making, and strange to say was brought to my notice by one of those who made a remark similar to that quoted above. To quote the "dissatisfied" workman—"I wish I had a night mate like this chap next me, he succeeds in getting out from 5 to 10 per cent more work than I do and appears to do so with a lot less trouble." Upon inquiring from the lad referred to I learned that the man on the night shift was his own brother and that they had made a close study of the machine and operation, with the object of making the most of their opportunity. "We always endeavor," he told me, "to have a few minutes together on the change of the shift to explain anything that will possibly assist the other in his work during his period. By doing this we can learn the condition of the shells then passing through, whether it is a series of hard or mild steel, so as to guide us in the grinding of our tools and the general operation of the machine. Not only in the actual operations do we have a mutual understanding, but in the location of all accessories such as oil cans, wrenches, gauges and all other tools, we have made a practice of having these always in their own place so that no hunting is required when one or the other of us require them. By this method we have been able to devote all the time to the actual work in hand and I believe that our record is not equalled by any other two men in the shop."

It was not that either of these young fellows were better workmen than others in the shop, but that they had started out with the idea that a minute saved was a minute earned, and in the piece-work principles of production the minutes saved invariably meant money earned. The results of these two men were not only satisfactory, but highly profitable.



OUTDOOR SUBSTATION AT NEW WESTINGHOUSE PLANT.

Man vs. Nature in Manufacture of Diamonds

Experiments Have Been Conducted Trying to Devise Process That Would Successfully Produce Precious Stones—Attempts Have Been Made to Melt Carbon, but With Indifferent Success

By SIR CHARLES PARSONS, F.R.S.

MANY theories have advanced to account for the origin of diamonds, but I propose on this occasion to confine myself to what has been done in the way of systematic researches and investigations on this subject, and to consinder whether it is possible to arrive at reliable and definite conclusions based on adequate foundations.

Henry Moissan must be credited with having been the first experimenter to make, and to identify with certainty, genuine artificial diamonds. In the "Fours Electrique," published in 1897, his researches and experiments are very fully described in minute detail. He generously alludes to the previous experiments of Marsden, published in the Proc. R.S., 1880-1881, and says he was the first to observe that if silver is melted in a carbon crucible and raised to the melting point of steel, on cooling, black diamond is sometimes found in the centre of the ingot. He moreover, states that he has repeated the experiments of Marsden and found that when a small mass of silver is quickly cooled, a satisfactory yield of black diamond results, but that transparent diamonds are never produced in silver. Moissan further adds: "The work of Marsden is of the highest interest, because he observed quite correctly the great number of different crystallized products which may be formed at the solidifying point of silver when it gives up its oxygen, alumina, silica, silcide of carbon, &c." Moissan in 1892 developed the electric furnace and applied it to his classical experiments, which resulted in the production of minute transparent diamonds in small ingots of iron, and also black diamonds in ingots of silver, when highly heated and quickly cooled in water or in chills. Moissan attributes the formation of the diamond in silver and also in iron to the compressive forces produced by the contraction of the outer layers and dilation of the molten nucleus when setting.

What occurs in a mass of iron so treated, I propose to discuss at some length, and to lay before you evidence that the gases occluded in the metal are the real cause of the production of diamond, and not the bulk pressure as has been previously supposed. We shall see that the weight of diamond found in an ingot of iron has in one case reached 1 ÷ 20,000 part of the weight of the ingot, or about 1 ÷ 1000 part of the carbon present—and that its quantity is of about the same order as the amount of carbon present as carbon monoxide occluded in the ingot. Moissan expressed the opinion that iron in a pasty condition was the matrix of the diamond, and that great pressure was the determining factor, which compelled a minute fraction of the carbon present to appear as diamond, and in his experiments he further speaks of the probability of carbon being liquefied when under a pressure sufficient to prevent its volatilization, and that from the liquid state it may pass into the crystalline or rounded form on cooling. Crookes, in his lecture delivered before the British Association at Kimberley, in 1905, emphasized the same view as to the probability of the crystallization or carbon directly from the molten state on cooling. Crookes in the same lecture also stated: "It is certain from observations I have made, corroborated by experience gained in the laboratory, that iron at a high temperature and under great pressure conditions existent at great depths below the surface of the earth—acts as the long-sought solvent for carbon, and will allow it to crystallize out in the form of diamond."

There is no prima facie reason against this view. The calories evolved in the combination of graphite and oxygen are about ½ of one per cent. less than those evolved in the combination of diamond and oxygen, indicating that graphite at ordinary temperature is, to this extent, the stable state. The bulk pressure which has operated in some of our experiments would, however, seem to have been amply sufficient to turn the balance in favor of diamond instead of graphite. The uncertainty, on the other hand, as to the compressibilities and specific heats of the allotropic forms under high pressures and at high temperatures renders speculation of little value as to what may occur at the melting point of carbon. All we know is, that up to the pressures and temperatures reached in our experiments no indication of a change from graphite to diamond has been produced.

I will now briefly describe some of our experiments which seem to bear most directly on the subject. Before doing so it is desirable first to describe the apparatus employed.

The first experiments were made in 1886 to 1888 under an 80-ton press and with current supplied from a turbo-generator of 35 horse-power; the results were given in a paper to the Royal Society in 1888. The experiments were resumed in 1907 with a new equipment which consists of a 2000-ton hydraulic

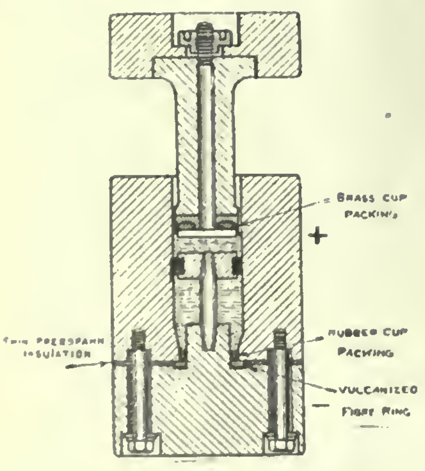


FIG. I

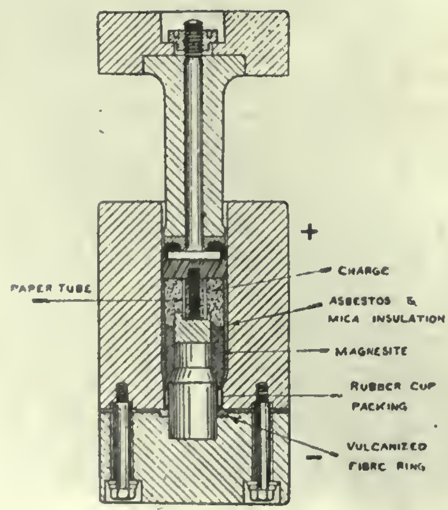

FIG. 2.

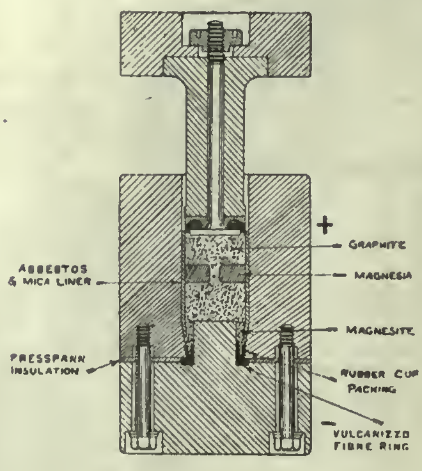

FIG. 3

press and a storage battery of 360 kilowatts normal output. The battery can be coupled for 2, 4, 8, 16, 48 volts as required, and the mains and main switch can carry currents up to 80,000 ampères to the hydraulic press, which is placed by itself in a small strong house, partly below ground, with walls of 2ft. thickness reinforced with steel bars—the door is of steel 3in. thick—the roof is of light galvanized iron. The moulds under the press are further enclosed by 2in. thick telescoping steel rings raised into position by steel ropes and counterweights. These precautions, as experience proved, were necessary, as several violent explosions occurred which cracked the steel rings and blew off the roof. A charge of iron and carbon when confined and raised to a high temperature may be very violent if suddenly released by the melting of the pole pieces. A steel mould of 9in. diameter was first used, but smaller moulds of 4in. and 2in. diameter have given satisfactory experiments and are more easily and quickly repaired and admit of higher pressures under the press. We will first consider the experiments on carbon and compounds of carbon when heated under pressure by means of a central conducting core through which an electric current is passed.

The result of treating benzine, paraffin, treacle, chloride and bisulphide of carbon, &c., under pressures up to 4400 atmospheres resulted in the production of a soft coating of amorphous carbon on the heating rod, and when the current was very intense the carbon rod and the contiguous layer were transformed into graphite. In one experiment several pounds of carbon dioxide snow were added to the charge, which consisted of magnesia, and was so arranged that evaporation of the heating carbon rod took place in an atmosphere of carbon dioxide and carbon monoxide, under a gaseous pressure of 4400 atmospheres, the condensate resulting being soft graphite. Upwards of 200 chemical reactions arranged to deposit carbon were tested under high pressure and central heating. After each experiment samples were taken from various parts of the charge and carefully analysed for diamond, the methods of the analyses generally following those of Moissan and Crookes. Small residues of diamond occasionally occurred, but the appeared to be associated with the presence of iron in the charge, whether introduced intentionally or from the melting of the pole pieces, short circuits, or from other causes. On the whole, there was no evidence that diamond had been produced by any of the chemical reactions, some of which were violent and caused explosions, and expanded the container. Some were endothermic, such as carborundum and sodium carbonate, which produced a grey solid which detonated.

We now pass on to consider the experiments designed to melt carbon in bulk, and I deal with them in some detail because so much prominence has hitherto been given to this aspect of the question. The barriers used were composed of quick-lime, marble, titanium oxide, or magnesia calcined in the electric furnace; of these magnesia gave the best results, being the more slowly converted into carbide. Intense heat was applied in one experiment for 5 sec., but sufficient in amount to melt the graphite core six times over, the only result being a slight alteration of the structure of the graphite. Threfall independently came to the conclusion from his experiments at about the same time (1907), that under 100 tons, or 15,000 atmospheres pressures per square inch, graphite, electrically heated, remained graphite. It appeared, however, desirable further to investigate the possibility of carbon losing its electrical conductivity when approaching its melting point, as alleged by Ludwig and others, and of shunting the current from itself on to the contiguous molten layers of the insulating barrier surrounding it. There had, however, been no indication of such a change having occurred, even momentarily; it rather seemed that the graphite core had been partially vaporised and condensed in the cooler parts of the charge. The experiment was, however, repeated with rods of iron and tungsten imbedded in the core, so that should the temperature of volatilisation of the metals under a pressure of 12,000 atmospheres exceed that necessary to liquefy carbon under the same pressure, the presence of these metals might produce a different result| No change, however, occurred, though in one experiment the pressure was raised to 15,000 atmospheres. A different method of attack was then arranged which would ensure that carbon should be subjected to an extremely high temperature concurrently with high pressure, obtained by the rapid compression of the hottest possible flame, that of acetylene and oxygen, with a slight excess of the former to provide the carbon. The arrangement was as follows:—A very light piston made of tool steel was carefully fitted to the barrel of a duck gun of 0.9in. bore; the piston was flat in front, lightened out behind and fitted with a cupped copper gas check ring, the cup facing forward; the total travel of the piston was 36in. To the muzzle of the gun was fitted a prolongation of the barrel formed out of a massive steel block, the joint being gas-tight. The end of the bore in the block was closed by a screwed-in plug made of tempered tool steel, also with a gas-tight collar. A small copper pin projected from the centre of the plug to give a record of the limit of travel of the piston. The gun was loaded with 2 drachms of black sporting powder, which amount had been calculated from preliminary trials. The barrel in front of the piston was filled with the mixture of acetylene and oxygen. It was estimated that this mixture would explode when the piston had travelled about half-way along the bore; when fired the piston travelled to within ⅛in. of the end, as had been estimated, giving a total compression ratio of 2888 to 1. As a result it was found that the surfaces of the end plug, the fore end of the piston, and the circumference of the bore up to ⅜in. from the end of the plug had been fused to a depth of about .01in., and were glass hard, the surface of the copper pin had been vaporised, and copper sprayed over the face of the end plug and piston. The end plug, which had been hardened and tempered to straw colour, showed signs of compression, and the bore of the block for ⅜in. from the plug was enlarged by .023in. in diameter, both indicating that a pressure above 15,000 atmospheres had been reached.

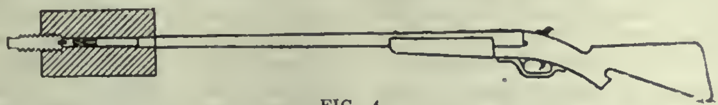

FIG. 4.

A little brown amorphous carbon was found in the chamber, which was easily destroyed by boiling sulphuric acid and nitre, there was no diamond residue from this. There was, however, a small crystalline residue from the melted layer of the end plug, from which was isolated one non-polarising crystal, probably diamond, but too small to identify with certainty. Considering the light weight of the piston and the short duration of the exposure of heat, the small diameter and volume of the end clearance space, the effects would seem to indicate that a very abnormal temperature had been reached, many times greater than exists in the chambers of large guns. There was, however, no evidence of any melting and re-crystallisation of the carbon present. A calculation made by Mr. Stanley Cook, based upon the ratio of

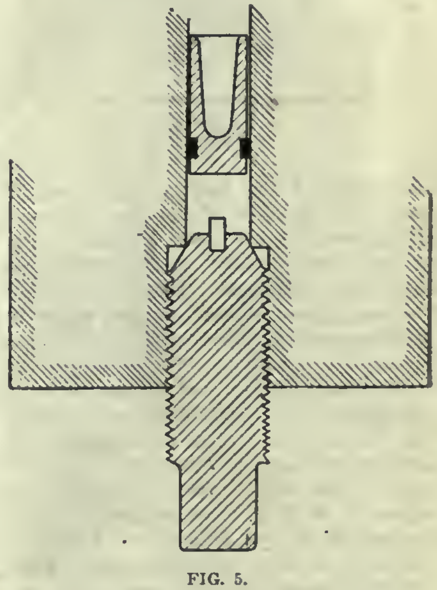

FIG. 5.

compression and a final pressure of 15,-0000 atmospheres, indicates that a temperature of between 15,250 deg. Cent. and 17,700 deg. Cent. was reached, the exact temperature depending upon the amount of dissociation or combination existing between the elements at the time.

It seemed desirable to try the effect of still higher pressures, so a rifle, .303 bore, was fitted with a specially strong breech mechanism by Rigby, capable of withstanding a charge of cordite 90 per cent. in excess of the service charge.

The gun was fixed with its muzzle 6in. from a massive block of steel, in which a hole, 303 diameter, had been drilled to a depth somewhat greater than the length of the bullet, and in alignment with the bore of the gun; cylindrical bullets of steel, with a copper driving band, were chiefly used, shorter than the service bullet, and about one-half of the weight, some with cupped noses to entrain material, some with coned noses to match the bottom of the hole in the block. The velocity with 90 per cent. excess charge was estimated to be about 5000 ft.-seconds. The substance to be compressed was placed either at the bottom of the hole when a conical-nosed bullet of mild steel was used, or over the mouth of the hole when a cupped-nose of tool steel was employed. About 100 experiments were made. The substances tested included graphite, sugar carbon, bisulphide of carbon, oils, &c., graphite and fulminate of mercury, finely divided iron and fine carborundum, olivine and graphite, &c. After each shot the bullet and surrounding steel were drilled out, and the chips and entrained matter analysed.

Several experiments were also made with a bridge of arc light carbon placed over the hole and raised to the limit of incandescence by an electric current, and the shot fired through it into the hole at the moment the carbon commenced to vaporise, as observed in a mirror from without. Also an arc bebtween two carbons was arranged just over the hole, and the shot fired through it.

Of all the experiments only two yielded a reasonable amount of diamond residue, one made with graphite wrapped in tissue paper, the bullet, however, in this case having grazed the side of the hole, and thus producing some molten iron by the friction; the other with the incandescent bridge, where again some molten metal would probably occur. The residues were in all cases exceedingly small, and not more than would be produced from a very small amount of iron melted, carburised, and quickly cooled.

There was no evidence of any incipient transformation of carbon in bulk into diamond that could be detected by analysis.

The pressure on impact of steel bullet fired into a hole in a steel block which it fits is limited by the coefficient of compressibility of steel, and with a velocity of 5000 ft.-seconds is about 2000 tons per square inch. Measurements made from a section through the block and bullet showed that the mean retardation on the frontal face after the impact till it had come to rest was abobut 600 tons per square inch.

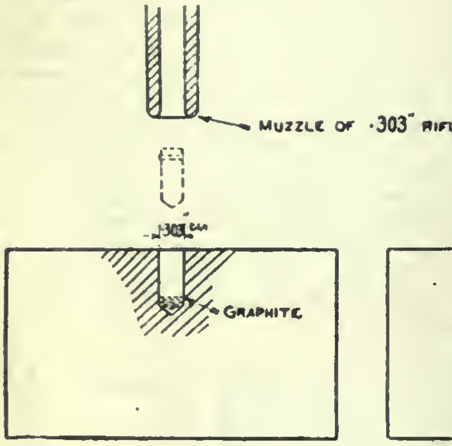

FIG. 6

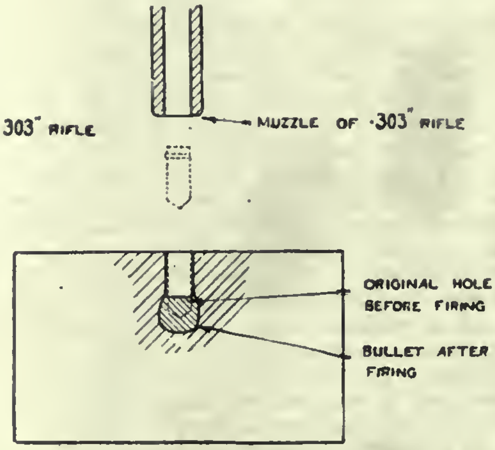

FIG. 7 .

Several experiments were made by substituting a tungsten steel block, and a hole tapering gently from .303in. at the mouth to .125in. at the bottom. The mild steel bullet was deformed by the tapered hole, and a greatly increased velocity imparted to the nose. Progressively increased charges were used ,and even with relatively small chargs the block cracked on the second round. With the 90 per cent. excess charge, the block always split on the first shot, but this probably occurred after impact, and not till the full instantaneous pressure had been exerted, which was estimated to be greater than with the plain hole, probablby exceeding 5000 tons, a pressure about equal to that at the centre of the earth.

In these latter experiments graphite was placed at the bottom of the hole. The analysis yielded nothing but graphite.

Experiments on Pressure in Cast Iron When Cooled.

It has been generally assumed that iron rich in carbon expands on setting, and that this supposed property is a contributory cause in the formation of diamond by increasing the pressure in the ingot.

We made several experiments by pouring iron, saturated with carbon, from the electric furnace through a narrow git into a very massive steel mould, closed at the bottom with a breesch screw—Fig. 9. When cold the breech screw was easily removed, and there was no sign of there having been any appreciable pressure on the threads. Not being sure that, because of capillarity, the corners of the mould had been quite filled, a steel mandril was, immediately after pouring, forced down the git hole by a press giving a fluid pressure in the mould of 75 atmospheres. The observed pressure on the breech screw appeared not to have exceeded this pressure. Highly carburised iron, therefore, does not expand with any considerable force on setting.

The reason why a lump of cast iron thrown into a ladle of molten metal first sinks to the bottom and soon rises and floats on the surface is probably that cast iron is about seven times stronger in compression than in tension. Therefore, when a sufficiently thick layer of cold metal has been heated, the interior is torn asunder by the expansion of the outer skin, and the specific gravity of the whole mass is diminished.

We may, therefore, safely conclude that when iron is suddenly cooled, the only compressive bulk pressure that is brought to bear on the interior is that arising from the contraction of the outer layers after setting, and with highly carburised iron this can only be moderate because of the low tensile strength of the metal, and cannot exceed about 1000 atmospheres.

Moissan observed that spherules or globules of iron with cracks never contained diamond. To such he attributed a loss of mechanical pressure; we now think that they merely provide an outlet for the occluded gases from the metal. We have made experiments by pouring highly carburised iron and alloys of iron on to iron plates, the cooling taking place from one side only, and under such conditions no diamond results; in fact ,it only occurs when the ingot or spherule is cooled on all sides simultaneously so that a gas-tight skin is formed all over before the centre is cooled.

Since my paper to the Royal Society, in 1907, the experiment of heating iron in a carbon crucible, and transferring it to a steel die, and subjecting it to 11,-200 atmospheres, has been repeated, this pressure being many times greater than can occur in a cooled ingot, and it has been found that if the iron is allowed to set bebfore the pressure is applied, the amount of diamond is much greater than if pressed when very hot, and while still molten, and that under the former condition it is about the same as when the crucible is cooled in water. The only reason that suggests itself to account for this is, that when pressure is applied, dwhile very hot, some of the iron permeates the carbon of the crucible, and because of the greater specific heat and lesser conductibility of the carbon, the iron next to and in the carbon remains molten after the ingot has been cooled from the top by direct contact with the steel cup on the face of the plunger; thus when cooling, the occluded gases have a free exit from the ingot through the molten metal (which is pervious to gas) into the carbon of the crucible, and are not retained in the ingot to the same extent as when it has set before pressing, and is enclosed on all sides in an envelope of iron impermeable to the gases.

These experiments, I think, it will be agreed, dispose of the bulk-pressure theory of the production of diamond in cooled iron. In fact, none of our experiments have shown that bulk-pressure has any effect whatever on the production of diamond unless in so far as it may affect the amount and distribution of the occluded gases within the ingot. Several experiments were made to try

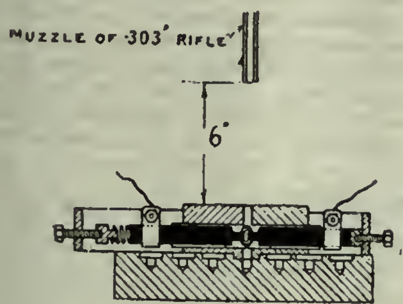

FIG. 8.

the effect of extremely quick cooling, by transferring a crucible with a charge of iron from the electric furnace to the press and submerging it in carbon dioxide snow, and also in water, at 6000 atmospheres—the analysis showed very little diamond. Other experiments where extremely quick cooling was effected not under pressure confirmed the view that quick cooling as such is not a factor in the production of diamond ,and that carbon is not caught in a state of transition by quick cooling.

Experiments were made on oxidising alloys of iron by superheated steam after heating in the electric furnace; large residues of crystalline oxides of the metals of the alloys resulted as had been observed by Marsden in silver, and there also was a small percentage of the residue (about 5 per cent.) of very minute crystals which burnt in oxygen, and had a specific gravity of 3.5, and are, therefore, diamond.

This part of the subject appears to merit further investigation.

Experiments Under Vacuum.

The presence of diamond in some meteorites suggested a series of experiments under various degrees of vacuum up to the highest obtainable.

It seems probable that in past ages some meteoric matter may have been melted by collision or ejected into space in a molten space and cooled by radiation, and that under such conditions absence, or diminution, of occluded gases might be a factor conducive to crystallisation of diamond.

More than fifty experiments were made with electrical heating of a carbon crucible under vacuum. Fig. 11 shows the first container used, which was evacuated to about 1-6 mm. of mercury by three steam jets in series with an air pump and jet condenser.

This apparatus was subsequently replaced by a molecular air pump of very large capacity working in series with two other pumps, which could maintain an X-Ray vacuum during the whole of an experiment. Fig. 12 shows the container. The suction outlet to the pump is 18in. in diameter.

When in this apparatus iron and alloys of iron were heated under high vacuum, the large volume of gas given off by the metal was very striking, and unless the heating was very gardual much of the metal was ejected from the crucible. It became quite apparent from the experiments that metal ejects the occluded gases slowly and absorbs them slowly. It was remarkable that in no experiment under a vacuum higher than 2 mm. was diamond ever found in the ingot crucible, but it was found in the ejected iron which had not fully parted with its occluded gases. Here again we have impressed on us by these experiments that occluded gases are essential to the production of diamond in cooled iron. Experiments were made under low vacuum—Fig. 10—averaging about 1in. of mercury, the gas in the container being 95 per cent. carbon monoxide. The heating up was prolonged and the cooling was effected solely by radiation and convection, and was relatively slow, occupying 15 sec. from switching off the current to the setting of the metal. Some of the diamonds produced in this way, the largest measured 0.7 mm. in length.

Let us for a moment recur to the experiments designed to impose the greatest possible bulk pressure on carbon and also on iron. The experiments designed to melt carbon have been carried up to 15,000 atmospheres steady pressure, and to 300,000 atmospheres momentary pressure, which pressures are nearly up to the maximum possible with the materials at our disposal. 300,000 atmospheres, or 2000 tons per square inch, is about one half the probable pressure at the centre of the earth—but only a fraction of one thousandth's part of the pressure at the centre of large stars or also of the pressure produced by the impact of large bodies in space. By such collisions and intense heating and cooling, short or prolonged, of large masses might occur by the adiabatic compression of the central portions of the colliding bodies. Under such conditions the Moissan effect might be produced on a large scale, and if heating and cooling of iron are the only essential conditions, would result in the production of large diamonds. One source of diamond may, therefore, be attributed to prehistoric falls of meteorites. The artificial reproduction of such conditions is obviously beyond our reach. Up to the present, as we have said, the only proved source of artificial diamonds is from iron or silver intensely heated, and then cooled with more or less rapidity. I now pass on to further consideration of this question.

We have seen that the evidence is very strong, or perhaps conclusive, that the occluded gases which escape on the setting of the metal and during cooling are a vital factor, and that unless such gases are retained within the ingot no diamond results. We have further seen that great pressure on the metal when molten and cooling makes no difference in the yield, also that the retention of the occluded gases is in this case likewise essential. The experiments under vacuum have shown that if the metal

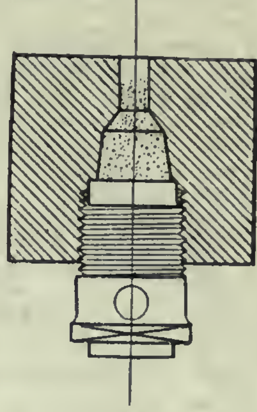

FIG. 9.

has had time to lose its occluded gases no diamond occurs, so that we may conclude that under all bulk pressures on the metal occluded gases are an essential factor.

Let us consider what happens inside an ingot or spherule when rapidly cooled simultaneously on all sides. It is first surrounded by a thin coating of solidified metal, which below 600 deg. Cent. is nearly impervious to gases. As the coat thickens, layer within layer, more and more gas is ejected by the solidifying metal, and is forced inwards, the diminishing nucleus of molten metal and its semi-solidified centre layer still pervious to gas receives the charge, and as this process progresses the pressure may rise higher and higher, though there may be a limit to the pressure against which the metal is able to eject gas when setting. All we, however, know is that the mechanical strength of the ingot or spherule places a limit of about 1000 atmospheres to the gaseous pressure when concentrated into a small nucleus. In the case of some iron alloys which occlude more gas than iron, most of the spherules are split or shredded with an appearance consistent with this view.

It would seem that the chief and only function of quick cooling in the production of diamond in an ingot or spherule is to bottle up, and to concentrate into local spots within it, under high pressure, the gases occluded in the metal which, during slow cooling, would partially escape, while the remainder would become evenly distributed throughout the metal.

Crookes' microscopical examination of diamonds with polarised light supports this view. I now quote a passage from his lecture at Kimberley in 1905. He says: "I have examined many hundred diamond crystals under polarised light, and, with few exceptions, all show the presence of internal tension. On rotating the polariser, the black cross most frequently seen revolves round a particular point in the inside of the crystal; on examining this point with a high power, we sometimes see a slight flaw, more rarely a minute cavity. The cavity is filled with gas at enormous pressure, and the strain is set up in the stone by the effort of the gas to escape."

Diamonds appear to be formed in the metal after it has set. Moissan found that the diamond occurred near the centre of the ingot, and he remarks that natural diamonds must have been formed in a pasty matrix, because they never show evidence of attachment to a hard body. But the most conclusive proof seems to be that we have found that a diamond is rapidly corroded by highly carburised iron just before setting, so that a microscopic diamond could not exist in molten metal for a second.

On the whole I think that diamond is probably formed at a temperature of about 690 deg. Cent., one of the points of recalescence, while the metal is still somewhat pervious to gases.

A heat treatment at high temperatures in the electric furnace appears to be essential ,and it is probably required to form carbides, within the mass, other than those of iron, and which react with the occluded gases after solidification. The view that carbon monoxide is the most important of the occluded gases is supported by the increased yield of diamond from iron which has absorbebd much of this gas before cooling, and also by the fact of its combination with the metals, and also with silica and sulphur as carbonyls. Its remarkable action in association with iron on carborundum appears further to emphasise this view. In this connection Carpenter observed some years ago that the gases given off from cast iron at red heat under high vacua contained silica. We have seen that in rapidly cooled iron the occluded gases must be much compressed at the time the diamond is formed, and Mond has shown that pressure, in the case of iron, increases the yield of ferro carbonyl ,and also is essential to the formation of the carbonyls of some other metals.

There is strong evidence to support the view that the action may take place solely between iron carbobrundum, sulphur, and carbon monoxide. It is, however, probable that other metals may also be involved, and that the action is one of great complexity. It must always be remembered that the yield of diamond is extremely small, and therefore very small traces of some of the elements may suffice to satisfy the action. Very little is, however, known and patient experimental research has here a most attractive field. As I have said, the largest percentage of diamond we found in cooled iron was estimated to be 1 ÷ 20,000 the weight of the iron, and 1 ÷ 1000 part of the carbon present, and if we assume that the iron contained a volume of carbon monoxide equal to .69 of the volume of the ingot—a common proportion — the weight of carbon in the carbon monoxide exactly equals the weight of diamond. The yield of diamond from the South African Blue Ground of the De Beers Mine in 1904 was 1 ÷ 5,400,000 of the weight, so that the yield from cooled iron in the best experiment has been 270 times greater.

I am not disposed to speculate, but may venture to suggest that it would seem probable that if a large mass of iron ,alloyed with other elements, was submitted to suitable heat treatment, and after setting, but when still at a temperature permeable to gas, was subjected to carbon monoxide at a pressure of about 1000 atmospheres for a long time that segregations might take place slowly within the mass, and diamonds in payable quantity and size might be produced. This experiment virtually consists in replacing the cold metal envelope thrown around the ingot by a gaseous envelope at a superior pressure, which will not only imprison the occluded gases, but further, by the ingress of additional gas into the metal, may induce the formation of diamond throughout the whole of the ingot. It may be found that higher gaseous pre sures than those permissible in a cooled ingot may increase the yield, and if is found to be the case they can be easily applied.

In rapidly cooled iron there is a steep temperature radient in the metal, but when under gases at high pressure it seems probable that the natural tendency to segregation on slow cooling may suffice to determine the local concentrations which form diamond.

The presence of crystals of silica, alumina and magnesia ,and the spinels and pyrope, &c., associated with diamond in rapidly cooled iron alloys, and also when oxidised by steam, appears to have a bearing upon the presence of similar crystals generally found in association with diamond and merits further investigation. The solution which I have indicated appears to be compatible with the conclusions of Bonney that eclogite is the parent-rock of the diamond in South Africa. He says: "Thus the diamond has been traced up to an igneous rock. The blue ground is not the birthplace either of it or of the garnets, pyroxenes, olivine, and other minerals, more or less fragmental, which it incorporates. The diamond is a constituent of the eclogite, just as much as a zircon may be a constituent of granite or a syenite. Its regular form suggests that it was the first mineral to crystallise in the magma." The solution we have suggested also accounts for so small an amount of carbon having escaped oxidation, for according to our view both the diamond and the eclogite have ben crystallised in iron at comparatively low temperatures.

It is possible that there may be other feasible solutions to the problem. For instance, it is possible that at a suitable temperature carbonic oxide under high pressure might cause diamond to crystallise in olivine, blueground, or eclogite, if some of the constituent elements were present, as metals and carbides, with some it would form carbonyls, and with others it would react.

A Modern Machine Shop and Its Management

The Proper Layout of the Plant Has Much to do With the Success or Failure of the Operations Carried on There—Essentials That Should be Kept in Mind in Constructing Shop and Tracks

No. 1 in Series of Articles by M. H. Potter.

GENERAL PLANS AND ARRANGEMENTS

As a rule the amount of land is limited and therefore a compact form is necessary. The compact form, capable of easy expansion in any direction, is chosen as likely to be the most useful one to those desiring information on this subject. The handling of materials and the transportation of them is made as simple, direct and economical as possible.

A railroad track should pass near the works, and from it a branch should be brought past the rear and to one side of the collection of buildings. Such an arrangement results in a great saving in the expense of hauling both material and product, and permits the general arrangement and development of the plant as here described.

Main Building

The main building or machine shop is divided lengthwise into a central portion, with side bays. The central portion is open clear to the roof and has a traveling crane of ample capacity moving over its entire length. The side bays are divided into a main floor, on a level with the central portion, and a gallery or second floor. This gallery is extended across the front end, thus connecting the two galleries and furnishing a platform by way of which the traveling crane may transfer material and product to and from the main floor. Along the center of these galleries and across the front runs a tram track, provided with light push cars for facilitating the transfers. Stairways are provided at each end in the center for conveniently and speedily reaching any part of the shop from floor to galleries.

At the front end of the machine shop proper are the offices connected with and forming a part of it, consisting of two structures with a driveway space between them. On the first floor of these are the offices, storerooms, etc., and in the other the tool-making room, a room for storage tools and fixtures, and a stock room, for the small finished parts. On the second floor is located the drawing room, while over the driveway is the pattern shop.

The offices are only those particularly connected with the manufacturing and shipping, and not the general offices of the company. A wing connects the front buildings with the foundry. The ground floor of this wing is used as a storage room for pig and scrap iron, and a flask room, while the second floor is a pattern storage loft, connected at one end with the pattern shop and at the opposite end with the foundry by a trap door directly over the train track leading through the flask room.

Foundry

The foundry is arranged with a central part and two side bays. The central part is covered by a traveling crane running the entire length. There are two cupolas, a large and a small one, served by two cranes of sufficient reach to swing into the central space covered by the traveling crane.

Large work is cast in the central space or within reach of the cranes, while small work and bench moulding occupy parts of the floor not covered by the cranes. On each side of the central part are tram tracks, which are crossed by one running to the flask room and one that goes through the chipping room and on across the yard to the machine shop.

A bay built on the side of the foundry toward the machine shop contains a platform upon which coal and iron for charging the cupolas are delivered by a tram car raised to that level by an elevator arranged for the purpose. This stock is weighed on track scales in front of the elevator. Beneath the cupola platform are the tumbling barrels, convenient to the cupolas for working over the slag, and to the chipping room for cleaning small castings.

The flask room is located at the front, while between it and the tumbling barrel space is the core room, containing a suitable core oven. At the opposite end, facing the yard, is the chipping and pickling room, where the castings brought in from the foundry are pickled, chipped and weighed, before being sent to the machine shop. If the castings are too heavy for convenient handling in the chipping room they may be run through to the yard and there handled by a boom crane covering the tram track upon which they are run into the machine shop. Castings of moderate size, yet too heavy to move by hand, are expeditiously handled by a light overhead trolley hoist in the chipping room.

At one end of the outer bays are the wash room and toilets.

Forge Shop

In the further corner of the yard, as far as possible from the foundry and engine room, is the forge shop, which is reached by tram cars, the track running through its length near the center. On the outer walls are the chimneys for the forges and heaters, and in the rear are the storage sheds for bar iron and steel, and space for coal. These adjuncts are in a shed built with brick walls and of such outline as to conform somewhat to the curve of the railway track, the forge shop having been so located as to admit of this arrangement.

Power House

The power house is located midway in the length of the machine shop, so that power may be applied to the line-shafting at a point that prevents much of the torsion incident to long lines of shafting driven from one end.

Near the boiler house is the chimney stack, with which the smoke flues of all the boilers are connected. Coal is brought in on push cars along the tram track, to the front of the boilers, where a track scale is placed for weighing it. Ashes are removed by the same tram track to whatever point is most desirable to deliver them.

Store House

Across the yard, at the rear end, is a store-house, for finished machines, or product. This connects with the rear end of the machine shop by a tram track running from the scales beneath the traveling crane through a wide doorway and the entire length of the store-house. The rear side of the store-house (next to the railway track) has wide, sliding doors, through which the finished product is readily moved into the railway cars for shipment. Here, as in the chipping room of the foundry, it may be desirable to make use of overhead trolley hoists to facilitate rapid and economical handling of machinery to be shipped. A space is left between store-house and forge shop for a branch of the tram tracks, as a convenient means of receiving material from the railway at this point.

Carpenter Shop

Adjoining the store-house is a carpenter shop. Thus the men who prepare the finished machinery or product for shipping are near their work, and the lumber used for this purpose, and the necessary machinery for cutting it up, are close at hand and require no unnecessary handling.

In the angle formed by the store-house and carpenter shop are the storage sheds for cast iron and steel chips from the machine shop, or for similar material.

Along the side of the yard extending from the forge shop to within 20 feet of the foundry, are arranged the stock sheds. These hold foundry sand and coal, engine coal, coke, etc., which is delivered into them directly from the railway cars, the track being raised to the proper grade after it has passed the store-house. It is continued the whole length of the foundry so as to deliver foundry sand directly into the windows of the foundry, keeping that in the storage shed as a reserve supply. Between the storage sheds and foundry is a gate, through which may pass a branch of the tram car track for receiving stock and material from the railway cars at this point.

Provision for Expansion

Whatever may be the size of the buildings of a manufacturing plant, or however carefully provision be made for all necessities for handling materials, etc., there is always the possibility, that some day the works will have to be increased in capacity or changed in form.

It is, therefore, important to consider these points at the outset, and to provide for an expansion of the business in accordance with future needs, and at the same time not disarrange or break up the general plan of the works. With these points in mind, the two following plans are given for enlarging the machine shop when more room is needed.

First, the building may be extended to the rear across the railway track, the rear wall being removed and the traveling crane tracks continued through the length of the additional building. Doors are provided for the passage of cars upon the railway track, and also a specially-built car habitually used for connecting the floors of the old and new building, its platform being on a level with the two floors. Thus the machine shop capacity could be increased to any reasonable extent.

Second, one, two or three bays may be built at right angles to the machine shop and on the side opposite the power house. These might be of one or two stories and of any desired length. They may contain traveling cranes to convey material to and from the traveling crane of the main shop, or have convenient trolley hoists and train car tracks, according to the character of the work to be done.

The capacity of the foundry may be increased one-third by extending it toward the power house. The same space may be obtained by using for foundry space that provided for chipping, core, and flask rooms, and providing space for the latter by extending the building toward the machine shop. The space, occupied by the wash rooms and toilets will, of course, be taken also, and these rooms placed in the gallery, as heretofore suggested.

To obtain additional power space for these enlargements the space occupied by the wash rooms and toilets may be utilized and these rooms provided for in an addition built toward the carpenter shop.

By some one of these plans or a combination of them, the capacity of the works may be at least doubled without seriously disturbing the general plan here described and without impairing the general efficiency of the facilities for handling the work.

This design is in as compact a form as is advisable, with a view of sufficient yard space. Where the amount of land is ample it would be manifestly desirable to spread out the design more by increasing the distance between the machine shop and foundry at the front, and the store-house and forge shop at the rear, or by lengthening the machine shop and thus add to the yard room.

Either of these plans might be employed where the extent of ground would admit of it, as it is always important to have plenty of room when it is possible, and it is seldom that we have too much yard space.

The newest form of shop roof should be of interest, as it tends towards perfect illumination and utility.

Appearance, uniformity, and symmetry have given way to practical usefulness, the object being to secure perfect, or rather as near perfect as obtainable, equal illumination over the entire floor, whether the buildings are large or small.

This has been one of the difficulties not entirely overcome, and in consequence of this drawback it has not been possible to construct buildings beyond a certain width, owing, in this respect, to a dark zone along the center. With this new method of lighting we may practically make them as wide as desired and be assured that the central portion is, for all practical purposes, as well lighted as near the side walls. This is a great advantage in buildings in which large machinery is to be constructed, as this class of work may be much more economically built in shops having but one storey; and as the earth furnishes the best foundation for a floor for heavy weights, this is desirable on that account.

grees, and the glazed portions an inclination of about sixty degrees.

Fig. 1, is a longitudinal section and Fig. 2, a cross-section of a machine shop with this type of roof. In Fig. 3, is given a perspective view of the machine shop completed, showing the general arrangement of the high central portion and the lower portions at each side.

The plan of the building shown is provided with a high central space for an erecting floor, over which a traveling crane is mounted, covering every part of this floor. The side portions are built considerably lower, as the same height is not here necessary or desirable. These portions are provided with smaller traveling cranes, running upon I-beams or girders which project into the central space, so that these cranes are capable of depositing their loads within the reach of, and under the main crane.

If much heavy work is to be done, each of the bays, on both sides of the central portion, is supplied with one of these cranes. By this means any load may be quickly and conveniently transferred from any one point, within any one of the bays to any point within any other bay, or to any point in the central erecting space, by the combined use of the main and secondary cranes.

In many cases it will be necessary to have these secondary cranes on one side only of the central space, the other side portion being reserved for machines and

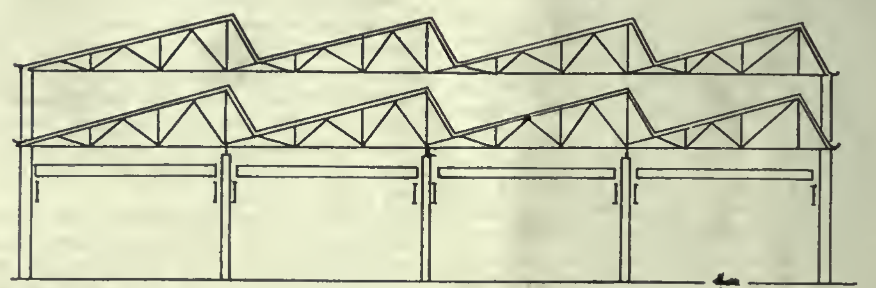

FIG. 1.

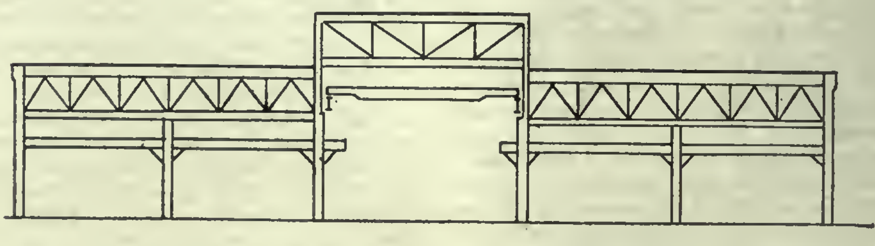

FIG. 2.

For this class of work a large area is needed, and to construct comparatively narrow buildings in order to have the center of the room well lighted, is expensive as well as inconvenient in moving large machines, or in working around them.

By this method of construction the buildings may be very broad and low and consequently easy to heat, and, as has been said, with good illumination over the entire floor.

The essential feature of the saw-tooth construction consists in forming the roof in broken sections, the roof proper having an inclination of about fifteen de-

work of the lighter description. So, also, it may not be necessary to equip all the bays on one side, even, with secondary cranes, while it may be necessary, and very convenient, to so equip several bays in this way. The nature of the work may be such that it will be convenient to equip several bays on each side and at one end with secondary cranes so as to arrange all the heavy work across the end of the shop, instead of along the side.

Fig. 1, shows the most approved form of truss for supporting this type of roof, and Fig. 2 gives the form of girders used to support the ridges of the roof where the glazed portion joins the roof proper. This construction is of light structural steel and no more members are used than is absolutely necessary, hence the entrance of light is very slightly interrupted and still there is sufficient strength for all practical purposes. The glazing of the light portions should receive much attention, in order to avoid leakage, as this is always one of the drawbacks of any kind of inclined windows.

For purposes of ventilation the sashes may be hinged at the top and opened by any convenient means. A simple device is to run a light shaft along inside the building and near the bottom of the sashes, and fix to it cast iron arms, in the form of cranks, for each sash. From these arms connecting rods run to the sashes. This shaft may be operated by fixing to it a grooved pulley, over which a small rope runs, and reaches down near the floor, from which it may be operated.

Ribbed glass should be used in these sashes as it prevents the glaring effect of direct and unimpeded sunlight, and diffuses a soft and agreeable light over the whole area to be lighted.

The roof timbers should be secured to the walls and to the posts by anchor bolts, to prevent the roof being lifted by high winds. In putting on the roof planking for this type of roof different methods must be adopted for the steel construction from that used for wood trusses and roof timbers.

In the case of the steel trusses, the supporting bars are shown in solid section in the longitudinal section, Fig. 1, and to these the planks may be secured by bolts, or lug screws, if steel supports are used, or by spikes, if these supports are of wood. In either case the planks will run in the direction of the pitch of the roof.

If the wood construction is used, the rafters will not be over 10 feet centers, and the planks long enough to reach at least two spaces, or 20 feet, ,and are spiked directly to the rafters, consequently they will run at right angles to them.

In case of either steel or wood construction, the roof planks should be covered with a good resin-sized roofing paper, mopped with hot tar, and upon this a heavy quality of roofing tin, or some form of the modern sheet steel roofing. All sheet metal should be painted on the under side before it is laid.

The gutters or valleys of these roofs should be the subject of careful attention. They need not be of sharp pitch, as a quarter of an inch to the foot will be sufficient. Conductor pipes at each gutter should carry off the water. In the case of the shop shown in perspective in Fig. 3, the gutters on the high central portion should incline each way from the center and from each side, conductor pipes carrying the water to the gutters in the lower part of the building, and from thence it flows to the conductor pipes at the sides.

Both of the methods above described for constructing the roof will be found economical to build and well adapted to the purpose for which they are to be used.

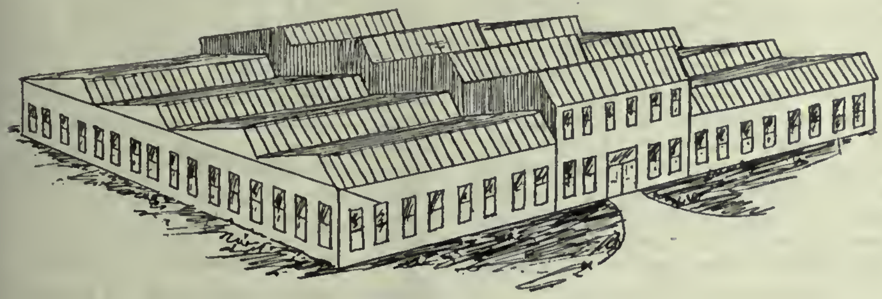

FIG. 3.

DEVELOP FLUORSPAR MINE IN B.C.

"The Consolidated Mining & Smelting Co. have started development of the fluorspar deposit which they bonded on the north fork of the Kettle river," writesA. E. Haggen. "This is one of the most important mineral discoveries recently made in the province of British Columbia. It is used in the manufacture of hydrofluoric acid, of which a large amount is consumed in the electrolytic lead refinery at Trail, and as a flux in silver-lead and copper ores. With the establishment of the iron and steel and glass-making .industries in British Columbia the existence of fluorspar will prove of great value. In the smelting of iron and steel fluorspar and phosphorus contents, and increases the tensile strength of the metal. Other uses are in the manufacture of spiegeleisen, foundry work, cupola, furnaces, manufacture of enamels, glazes, fireproof ware, apochromatic lenses, gems and carbon electrodes folr flaming arc lamps, so that the discovery of this deposit is not only of value in existing metallurgical industries, but in the future industrial development of the province. A good deal of the mineral has already been packed out on horses, but a road is being built to connect the deposit with the railway, a distance of about eight miles.

"'A tunnel is being driven on the Molly Gibson at Paulson. This property carries an appreciable amount of platinum in addition to the other mineral values."

STEEL SITUATION IN JAPAN

The steel rolling mill of the Kawasaki Dockyard Co. at Fukai, Kobe, will begin operations in a few days. The plant has a capacity equal to turning out 125 tons a day.

The Hokkaido Steel Works has completed the installation of a smelting furnace with a capacity of 100 tons a day. The new furnace was to start operations on Saturday, June 15.

It is reported from Osaga that France and Italy have started their purchase of Japan zinc, thereby enlivening the market here, which has been short of the visible stock on account of the curtailed output of refiners.

Big zinc refiners in Japan, including the Mitzui Co., Suzuki & Co., and others, are going to boost up prices of zinc by their united action to cut down the output. The probable extent of reduction is 25 per cent., it is said.

WOOD SHIPS FOR AUSTRALIA

The Canadian government has received an interesting statement in regard to the present position of shipbuilding by the Commonwealth of Australia. Actual contracts entered into by the government include 26 steamships and twenty-four wooden ships, with a gross tonnage of 200,600 tons. Twenty-seven distinct slips are bieng used for construction purposes. When these contracts are completed the Australian government will own a total fleet of seventy-seven vessels of a gross tonnage of 302,506 tons. Of this number fourteen vessels have been purchased in England and fourteen are being built in the United States.

At least one Nova Scotian vessel will, in all probability, be purchased by the Commonwealth government within an early date. The report states that as it is impossible to obtain adequate supplies of wire rope and the favored hemp sail canvas from the United States, the attention of Canadian manufacturers of these articles is directed to the development of Australian shipbuilding as an outlet for their products.

FLINT AND TINDER AGAIN

The manufacture of tinder-box flints is booming just now owing to the match shortage.

This is probably the oldest handicraft in Britain—older, in fact, it could hardly be, for it forms an industrial link—the only one—with the prehistoric Stone Age.

The centre of the industry is the little village of Brandon, on the borders of Norfolk and Suffolk. The men who pursue it are known locally as flint-knappers, and the work is done in little sheds, often situated at the back of the cottages in which the workers live.

In pre-war days the demand for the flints they produced came chiefly from Spain and Italy, in the rural areas of which countries the old-fashioned flint-and-steel tinder-box has never been wholly supplanted by the modern match. But nowadays practically the entire supply is eagerly snapped up by the makers of those ingenious little mechanical devices for lighting pipes and cigarettes with which the war has rendered us familiar.

Rust Spots Turned Out to be Only Oil Stains

Peculiar Problem Came Up in Large Montreal Plant, Where Inspector Was Sure There Was Defect, While Superintendent Held His Shop's Work Was Well Done—Oil Was the Cause

ONE of the many causes of rejected shells has been the appearance of what the inspectors term "rust spots" on the walls of the bore. Inability to state definitely the causes of the formation of these spots has resulted in the holding up of finished shells until the objectionable feature has been removed, or until a district inspector has permitted the shells to pass. A notable instance of this was brought to the attention of the wrier some few weeks ago by the superintendent of a large munition plant manufacturing 6 inch high-explosive shells. After mastering ali the details in connection with the machining of the shell the work of production was proceeding with increasing regularity when the presence of these so-called "rust spots" was discovered by the inspector, and, despite all argument or contention on the part of the plant officials that the shells were almost perfect, the inspector insisted that shells showing such blotches could not be accepted.

Searching for the Trouble

Certain that these spots were not detrimental to the shell or its subsequent action, the superintendent determined to investigate and convince the inspector that such shells were as perfect in every particular as any others passing inspection. On closely examining several of the shells that had been turned down, it was invariably found that these objectionable blemishes were located about midway of the length of the shell bore. Further investigation showed that in few instances did these spots appear near the nose or at the base of the shell. Believing that rust spots would not be confined to any particular portion of the shell, the superintendent set to work to find out just what would cause these spots to appear. Carefully studying the various operations through which the shell passed it was thought that during the process of nosing was the most likely period in which the spots would be created.

Lubrication of Nosing Die

As is generally known it is the practice to swab the bottling die with oil to lubricate the surface to facilitate the operation and avoid undue wear upon the die. The use of oil also assists in the release of the shell after the nose has been formed, the sudden heating of the oil causing a gas to form in the shell, and the rapid expansion of this gas tends to eject the shell from the die.

Believing that here might be found the seat of the trouble, a close study was made of the possibilities resulting from the presence of this oil on the interior of the shell. As might be expected, when the workmen are lubricating the die, little attention is given to the amount of oil swabbed on, so that a splash is very likely to find its way into the open end and lodge on some section of the inner wall. In the heating of the shell prior to nosing, the open end is placed in a special furnace, and for a distance of approximately three inches is heated to a forging temperature. This high temperature is confined to the portion subjected to nosing, but the heat cannot be stopped at a definite line, and consequently the temperature gradually lessens towards the base of the shell.

Conclusions Arrived At

Accepting this as a basis of operations three distinct conditions were arrived at; first, the heat at the extreme nose was so great that a splash of oil on this portion would immediately burn off, leaving no trace of oil or carbon content; second, the portion near the base was comparatively cool, so that oil falling on this section would remain virtually in a normal state, being subsequently removed by the sand-blasting or washing process; third, the portion midway between the heated nose and the base would be of such a temperature that the liquid portion of the oil would be burned off but the heat not sufficient to consume the carbon content, this being deposited into the pores of the metal in such a manner that the spot affected would take on a different color to the surrounding metal, creating the condition that had given rise to the "rust spot" theory.

Attempts had been made to eliminate these spots by sand-blasting but little success could be accomplished, the only result being to produce a slight hollow at the affected spot.

Proving the Theory

To prove the conclusions arrived at from the study of the nosing operations, two shells were carefully selected that were practically identical in every particular, with the bores of both perfectly clean and smooth. The nosing die was cleaned and all trace of oil removed, the shells heated and bottled in the usual manner, without lubricating the die. One of these shells was afterwards placed in a furnace and the entire shell heated to a temperature corresponding to that generally attained midway of the length when the ordinary nosing process is performed. This shell was then swabbed with oil over the entire surface of the bore and allowed to cool. When cold these two test shells were cut in half, lengthwise, for close examination.

When these were closely inspected separately, one could not detect any difference between the walls of the shells, but when the four halves were placed together the contrast was quite striking, the surface in each case being quite clear and uniform, but the shell that had been treated with oil was of a slightly darker color than the other. One of the "rust spotted" shells was also cut in a similar manner and carefully examined in conjunction with the test shells, and the contrast between the rust spot or stain was exactly the same as that of the two shells treated for experiment. Little difficulty was experienced after this regarding the presence of these oil stains.

COMPRESSED AIR FOR CLEANING MOTORS

By Meredith.

In a great many manufacturing plants, especially those working in wood or a similar material, the driving motors have a tendency to become clogged with dust in a short time. Such accumulation of dust is a fire hazard, particularly if the motors are overloaded and liable to have coils burn out; and if a motor is not overloaded it may heat if the air ducts are filled with dust. Moreover, the motor is not able to carry the peaks when called upon, for the reason that the additional heat cannot be dissipated. Motors should be cleaned frequently, but such cleaning with the means ordinarily at hand is a rather difficult procedure since the air ducts are necessarily usually small and difficult to clear with a brush. The windows may be brushed off externally but such cleaning does not reach the real seat of the trouble.

One of the best methods is compressed air under considerable pressure. If the air is not available from some source already in use, it is advantageous to use a small motor driven compressor and a storage tank. The compressor should have a capacity of from 4 to 10 cubic feet of air per minute at a pressure of 100 pounds per square inch, and the tank should hold from 40 to 100 cubic feet. This size will take care of the average plant.

In piping a factory the air line can be in 1 in., ¾ in. and ½ in. pipe. Since the amount of air used in cleaning any one motor is small, a large pipe is not necessary. An outlet with a valve should be placed near each motor, or if they are grouped, several motors can be reached from one outlet with ½-inch or ⅜-inch hole. The smaller size is more easily handled. The nozzles can be made up of bras rod of suitable sizes and shapes, which, however, must have very small openings, as a large nozzle opening would consume too much air. Probably the most useful sizes would be 3/32 inch, 1/16 inch, and 3/64 inch, and these three nozzles will meet most conditions.

Sometimes it becomes desirable to clean surfaces with air; for instance, the walls or ceilings of the buildings. This may be done with a tool made from ⅜-inch or ½-inch pipe in which there are a number of holes, to form a "brush" of escaping air. For ordinary purposes holes of about 1/32 inch to 1/64 inch can be used.

These small nozzles do not clog readily if all the scale and dirt is blown out of the piping. As an investment such a cleaning system will be found to pay for itself in the reduction of motor troubles and the decrease in fire hazard.

OILS AND THEIR USES

By M. M.

EVERYONE knows something about the usefulness of oils in the workshop, but there are a great many who employ them indiscriminately, thereby making more or less serious mistakes. A little general understanding and commonsense is necessary, and also a little discernment as to the nature of the oils which are useful in everyday use. A very common mistake is to oil a sewing machine, bicycle, pram or clock with any kind of oil which happens to be handy. Frequently these are oiled too often and yet again they are oiled too seldom, being left till they squeak. Then they are given too much oil, often of the wrong sort, and then there is more trouble. The right oil to use for a clock, no matter what sort it is, is clock oil, which is a clean, thin lubricating oil that does not dry or get sticky. It is also suitable for any light machinery. The least possible touch of oil on the working parts only of clocks will suffice, and as the movements are slow, they do not need it often. Now if this oil were used for sewing machines and the like, they would require it too often, so a machine oil with more body is best used very lightly, but as frequently as may be needed to keep all the parts slightly greased. Fast-running machinery requires oiling the oftenest. Whereas once a year might do for a clock, once a day would be necessary for a machine in constant use. And the heavier the machinery the heavier the oil should be; engine oil is really heavy machine oil.

Linseed oil, in appearance, might seem to be a good lubricant; but it is altogether unsuitable. It dries like a hard varnish, and, of course, would clog any machinery almost as badly as varnish would, except that it hardens slowly. If a piece of rag that has been used in apers oil, and another wet with linseed oil, be left exposed to dry air for a considerable time, the former will be still the same, but the latter will have become stiff and heavy. For this reason it is quite unfit for using on hones and whetstones when sharpening tools, for it makes them hard and useless, but it is always around woodworking shops, and thus many workmen have spoilt their stones before finding the reason out. If used for oiling the bright blades of saws or other tools, it makes them brown and varnishy. But linseed oil is the very best for rubbing into the wood parts of tools to keep them clean, and it imparts a hard, finished surface. For woodworking and polishing it is invaluable; also, in the manufacture of varnishes, oilcloths and imitation leathers. Boiled linseed oil is the only kind for mixing paint; or it would never dry. It is also essential for making putty; the best is made from raw linseed oil and whiting. Very often cotton-seed oil is used as a substitute for linseed oil but is a very poor substitute. Linseed oil is useful for domestic purposes in reviving varnished furniture and leather goods. It is sometimes employed for machine belting, but castor oil is considered best for the purpose, also for the leather of bellows and such like articles, where suppleness and durability are required. As it is expensive, however, palm oil makes a good substitute.

Petroleum or paraffin, besides being the recognized burning oil for lighting and heating purposes, is excellent and cheap for cleaning the working parts of machinery before lubricating. It is good for thinning down machine oil before lubricating and makes a capital lubricant for locks and light machinery, if a little sperm oil is added. For sharpening tools on the whetstone, many workmen prefer it to any other.

THE INSPECTION DEPARTMENT

By M. R.

In the days before the war the engineering shop with an inspection department and a special staff charged with gauging and measuring each article produced, to see that it conformed to a minimum standard of accuracy, was regarded as a rather "advanced" concern. In the vast majority of general engineering shops the foreman kept a more or less vigilant eye on the work sent forward by his department, and the manager, personally or by proxy, inspected a finished job before despatch; but otherwise, the responsibility for seeing that faulty work was not turned out rested on the workman himself. He worked to a standard prescribed by his skill and self-respect, and the fear of bad work being found out and reported upon either by some other department or by the customer kept him up to the mark. But the war has changed all that. It has changed engineers into manufacturers of interchangeable parts, which stand to be rejected if they are not up to size within the plus and minus limits prescribed. In these circumstances it pays to set up a system of inspection whereby every patch of work is examined, for by so doing, faulty work can be discovered at once, and the man or machine promptly attended to. An instance of the saving effected by proper inspection is given by Mr. C. Turtle in an address to the Junior Institution of Engineers. A firm undertook a contract to supply half a million of a certain piece of ordnance mechanism, which involved something like 200 machine operations. For the first 100,000 the rejections were between 12 per cent. and 15 per cent. and it was soon realized that there was something seriously wrong. It was decided that the manufacturing side was all right, but that the inspection organization as it then existed, was not up to the new requirements. An inspection department and staff was therefore created, with the result that in the second contract for a further half million, the Government rejections dropped to 0.17 per cent. For the last 300,000 parts delivered under the contract the Government rejections only amounted to 0.034 per cent., which is believed to constitute a good record. That these exceedingly good figures were not obtained at any undue expense in material rejected at the works, was proved by the fact that the works scrap only amounted to 4 per cent. of the metal cut up. The improvement was obtained by prevennot only entailed an investigation of the gauges in use, but of them ethods by which they were handled and used, the machine operations and the personnel of the whole department. The practice of inspection, though vastly extended by the multiplication of war orders, will certainly not subside with the end of the war, for, quite apart from the execution of orders having size limit specification clauses, there are great economies in working to a proscribed degree of accuracy. Mr. F. W. Lanchester gave a good instance of this in his paper on worm gearing. Some years ago in designing certain mechanism Mr. Lanchester himself set every clearance dimension and tolerance dimension and these were worked to for a considerable time with satisfactory results. A new works manager, who did not believe in working to fine limits, reported that the limits were unduly fastidious, and that money could be saved by relaxing the limits and so avoid having to scrap part. The managing director consented, and the scheme was tried. A slight and questionable reduction resulted in the cost of manufacturing components, but the increased cost of assembling and testing, and the cost of rectifying complaints, etc., became so great that the initial saving was swallowed up many times over. Within twelve months the scheme was abandoned, and the old fine tolerances were restored, the expense of twice altering the gaugs, etc., being a dead loss, apart from the disastrous results of the experiment. It is but another instalment of the old story that what is gained by scamped work in the machine shop may be lost ten times over by extra work on the fitter's bench.

Hints on Steel.—Sanderson Bros. and Newbold Ltd., of Sheffield, England, have recently published a new issue of this instructive little 96 page booklet, covering all the essential details in connection with the working, hardening and tempering of their various grades of light speed and carbon steels. This booklet is very complete and will be found of great value to steel users. H. A. Drury Co. are the Canadian distributors.

Rapid Growth of Canadian Railway Club

At Present Time There is an Enrollment of 883 Members—Forty-five Members Are Now Overseas, and the Club Has Been Active in War Work at Home

THE Canadian Railway Club with headquarters in Montreal has made rapid progress during the past few years, both in the strength of the membership and the services the club has been able to render these members. The club has at the present time an enrollment of 883 members.

Over 45 members have enlisted for overseas' service, five of whom have since been killed in action, three wounded and returned. The retiring president, G. E. Smart, was untiring in his earnest enthusiasm throughout the year, and the success of the past season has been due very largely to his energetic leadership and that of his lieutenants. The papers and discussions of the sessional period were very instructive and educational in character, dealing particularly with subjects pertaining to problems created by existing abnormal conditions in connection with railroad work and organization; these papers were prepared by prominent railroad men in various branches of the service.

The inauguration of the Canadian Railway Club took place early in 1902. The advantages that would result from the formation of a society for the better education and co-ordination of its members was recognized by several local railroad officials who had previously experienced these benefits from similar institutions in the States. The preliminary meeting of the club was held on the 15th of February at the Queen's Hotel, Montreal. Prominent amongst those responsible for the initial movement were E. A. Williams, W. H. Rosevear, S. S. Underwood and M. P. Kelley. A general meeting was called for the 11th of March at the Windsor Hotel, at which the new Railway Club was organized and a committee appointed to draft out a constitution and the necessary by-laws. Twenty-six representative members were present at this meeting and the club started out with approximately 175 charter members. The first officers of the Canadian Railway Club were E. A. Williams, Supt. of Rolling Stock, C.P.R., president; T. A. McHattie, Master Mechanic, G.T.R., 1st vice-president; S. King, Master Car Builder, I.C.R., 2nd vice-president; M. P. Kelley, Chief Clerk Car Dept., C.P.R., secretary; S. S. Underwood, Draughtsman, G.T.R., treasurer. The executive committee were W. H. Rosevear, Jr.; Jas. Powell, T. H. Hopkirk, F. Sutherland and Acton Burrows.

Objects of the Club

The principal objects of the Canadian Railway Club are given in sections 1 and 2 of the constitution; first, the object of the club shall be the dissemination by means of reports, papers, investigations, and the discussion of knowledge concerning the construction, operation, and maintenance of railroads and railroad equipment, and the cultivation of sociability among its members. Second, no patentees or their agents or agents for the sale of railroad supplies, shall occupy the attention of any club meeting in the interests of the device in which they are personally or financially interested, unless they are especially invited to do so by a majority vote of the members present, or by consent of a majority of the executive committee, and the article they represent forms a part of the subject of discussion.

The Officers For 1918

The officers elected for the ensuing year were as follows: President, C. W. Van Buren, Gen. Master Car Builder, C.P.R., Montreal; 1st vice-president, T. C. Hudson, Master Mechanic, C.N.R., Joliette; 2nd vice-president, J. Hendry, Master Car Builder, G.T.R., Montreal; executive committee: W. H. Winterrowd, Chief Mechanic Engineer, C.P.R., Montreal; C. H. N. Connell, Division Engineer, C.N.R., Montreal; Arthur Crumpton, Asst. Valuation Engineer, G.T.R., Montreal; E. A. Nix, Asst. Works Mgr., C.P.R., Montreal; W. H. Sample, Supt. of Motive Power, G.T.R., Montreal; B. F. Shortley, Terminal Agent, I.C.R., Montreal.. Audit committee: D. R. Arnold, Sales Manager, Can. Car & Foundry Co., Montreal; Geo. Whiteley, Asst. Supt. of Motive Power, C.P.R., Montreal; G. M. Wilson, Master Mechanic, G.T.R., Montreal. Treasurer, E. E. Lloyd, Auditor of Disbursements, C.P.R., Montreal. Secretary, Jas. Powell, Chief Draughtsman, G.T.R., Montreal.

C. W. VAN BUREN, PRESIDENT

General Master Car Builder, Canadian Pacific Railway, Montreal

Starting his engineering career with the New York Central in 1889 being employed in the West Albany Car Shops. In July, 1905, he accepted a position with the Canadian Pacific Railway, as General Car Inspector. In 1906 he was appointed Divisional Car Foreman of the then Eastern division. He was appointed Master Car Builder of the Eastern lines, in the year 1909. He left the C.P.R. in 1911, to accept a position with the Union Stock Yards and Transit Co., of Chicago, Ill. Returned to the services of the Canadian Pacific in April, 1915, to the position of General Master Car Builder, with headquarters at Montreal.

GEO. E. SMART, PAST PRESIDENT

Master Car Builder, Canadian Government Railway, Moncton, N.B.

Started his mechanical career with the Grand Trunk Ry., in 1895, and in 1904 he left to accept a position as Supervisor of car heating and lighting with the Canadian Pacific Railway. He was appointed to the position of General Car Inspector in 1906. Three years later he was promoted to Divisional Car Foreman of the Eastern division. He resigned from the C.P.R. in October, 1913, to accept the position of Master Car Builder of the Canadian Government Railways, and has recently been promoted to Superintendent of the Car Department.

T. C. HUDSON, FIRST VICE-PRESIDENT

Master Mechanic, Canadian Northern Ry., Joliette, P.Q.

Born at Brockville, Ont., February 20, 1873; educated at Brockville and the Carleton High School. Started apprenticeship as machinist in January, 1887, with the Canadian Pacific Railway at Carleton Place. Served as a general machinist for the C.P.R. at Chapleau, Carleton Place and other points until 1901, when he was appointed Asst. Roundhouse Foreman for the C.P.R. at Smiths Falls, retaining this position until 1903. From then until January, 1906, he was foreman of general repair shops at Carleton Place, and for the next year was Locomotive Foreman for the C.P.R. at Ottawa. He resigned from the C.P.R. in January, 1907, to accept the position of Shop Foreman with the Canadian Northern at Parry Sound. In July, 1907, he was promoted to Master Mechanic of the Canadian Northern Quebec Railway, and the following year had the additional duties of the Quebec and L. St. John Railway. In August, 1915, he was appointed Master Mechanic of the C.N.R. system lines east of Ottawa, with jurisdiction extending over the Car Dept., this being his present position.

J. HENDRY, SECOND VICE-PRESIDENT

Master Car Builder, G.T.R., Montreal

Mr. Hendry has been employed as Master Car Builder of the Grand Trunk Railway, for the Eastern lines, with headquarters at Montreal since 1908. Previous to this he had served for a number of years with the Canadian Car and Foundry Company at Montreal, in charge of the passenger car construction department.

W. H. WINTERROWD, EXECUTIVE COMMITTEE

Chief Mechanical Engineer, C.P.R., Montreal

Born at Hope, Ind., on April 2, 1884, being educated at Shelbyville, Ind., and Purdue University, whence he graduated with the degree of B.S. in 1907. He entered railroad service in 1905, the first year as a blacksmith's helper for the Lake Erie and Western Ry. at Lima, Ohio; from 1906 to 1907 he was air brake and car repair man for the Western lines of the Pennsylvania Railway at Dennison, Ohio. The following year he served as special apprentice with the Lake Shore and Michigan Southern Railway at Elkhart, Ind. From 1908 to 1909 he occupied the position of roundhouse foreman for the Lake Erie, Alliance and Wheeling Railway at Alliance, Ohio, and the next year was transferred to Youngstown as night foreman of the roundhouse for the Lake Shore and Michigan Southern Railway; the next year serving as roundhouse foreman for the same road, at Cleveland, Ohio, and from 1910 to Sept., 1912, he acted as assistant to the Mechanical Engineer at Cleveland. He then accepted a position with the C.P.R. as Mechanical Engineer of the Angus shops at Montreal. In May, 1915, he was appointed assistant to the Chief Mechanical Engineer, and on April of this year was promoted to the position of Chief Mechanical Engineer.

CHAS. H. N. CONNELL, EXECUTIVE COM.

Division Engineer, Canadian Northern Railway, Montreal

Born in Woodstock, N.B., August 26, 1876, and received his early education in the Woodstock Grammar School. His railway career commenced in 1897 when he engaged as a rodman on construction and survey for the Crow's Nest Pass Railway (C.P.R.). The following year he was a topographer on survey of the Rainy River Railway (C.N.R.). He was appointed roadman on construction for the same company in 1899. In 1900 he accepted a position as roadman on construction and Assistant Resident Engineer with the Algoma Central and Hudson Bay Railway and was promoted to Resident Engineer of the same road in 1901, retaining this position until 1903, when he accepted a position as Assistant Resident Engineer with the Halifax and South Western Railway. From 1903 to 1906 he was engineer in charge of Surveys and Maintenance with the Alberta Railway and Irrigation Company of Lethbridge, Alta. For the next three years he held the position of Chief Engineer for the same company. In 1909 he was appointed Engineer of Maintenance of Way, on the Quebec division of the Canadian Northern Railway. In 1914 he was appointed Divisional Engineer, and last year was given the office of District Engineer with headquarters at Montreal.

EDWARD A. NIX, EXECUTIVE COMMITTEE

Assistant Works Manager, Canadian Pacific Railway, Montreal

Born at Columbus, Ga., August 23, 1872. Entered the service of the Central of Georgia Railway at Columbus, Georgia, at the age of 18, as apprentice car builder. After finishing term of apprenticeship worked for a time as journeyman car builder and was subsequently promoted to Freight Inspector, Passenger Inspector, foreman of car cleaners, and assistant foreman of the car shops. In June, 1897, he was transferred to Macon, Georgia, succeeding S. A. Charpiot, as Master Car Builder. In May, 1905, he was appointed manager of the Lenoir Car Works, Lenoir City, Tennessee. Here he remained until September, 1907, when he accepted a position with the Bodley Wagon Co., Memphis, Tenn., being appointed vice-president and general manager of the company. Re-entered railway service again in Sept., 1911, taking charge of the Car Dept. of the Illinois Central Harnham shops at New Orleans, La. He was transferred to Memphis, Tenn., in the same position, in February, 1913. Entered the services of the St. L. & S. F. Ry. at Memphis in May, 1915, in charge of the car department. In November of the same year he was again transferred to Kansas City, Mo., as Car Superintendent of the Northern Division. He accepted his present position as Asst. Works Manager of the Car Dept. of the C. P.R. at Montreal in April, 1916.

ARTHUR CRUMPTON, EXECUTIVE COM.

Assistant Valuation Engineer, G.T.R., Montreal

Is a native of Toronto and has been with the engineering department of the Grand Trunk for many years in responsible positions connected with the locating of new lines, as well as in the designing and superintending of construction of many important engineering works for the railroad and its subsidiary lines.

W. H. SAMPLE, EXECUTIVE COMMITTEE

Superintendent of Motive Power, G.T.R., Montreal

Was born at Altona, N.Y., August 20th, 1864, and entered railroad service on his birthday anniversary in the year 1882. For five years he was a fireman with the Central Vermont Ry. at St. Albans, Vermont. From 1887 to 1890 he was locomotive man with the Atcheson, Topeka and Santa Fe Ry. at Albuquerque, N.M. He returned to the Central Vermont as locomotive man and after one year was appointed to the position of Road Foreman of Locomotives, remaining in this position until 1906. He then resigned to accept a position as Superintendent of Motive Power and Car Dept. with the Northern Railway of Costa Rica (United Fruit Co.), San Jose, Costa Rica. He then came to Canada and on March 15th, 1911, he was appointed to the position of Master Mechanic for the Grand Trunk at Ottawa. From October, 1914, to October, 1916, he was Master Mechanic of the G. T. R. at Battle Creek, Mich. He was then transferred to Montreal as Master Mechanic of the Eastern lines, and in the spring of 1918 was appointed Superintendent of Motive Power with headquarters at Montreal.

B. F. SHORTLEY, EXECUTIVE COMMITTEE

Terminal Agent, Intercolonial Ry., Montreal.

Born in Montreal on June 24th, 1866. His railroad career commenced in 1887 when he engaged as a switchman with the Grand Trunk Ry,. being subsequently promoted to Operator and then to Train Despatcher. In May, 1900, he accepted a position as operator with the Canadian Government Railways, and was afterwards appointed to take charge of the Commissionary Department at Montreal. He was in charge of the stores department for a number of years and for the past five years has been the Terminal Agent at Montreal.

D. R. ARNOLD, AUDIT COMMITTEE.

Sales Manager, Can. Car & Foundry Co., Montreal.

Started his mechanical career in 1904 with the Barney and Smith Car Co., of Dayton, Ohio, in the mechanical department. He was transferred to the estimating department in 1910 and the following year was promoted to assistant to the President. On the first of March of the same year he accepted a position in the estimating department of the Canadian Car & Foundry Company of Montreal, and in 1914 was appointed Sales Manager for the company.

GEO. WHITELEY, AUDIT COMMITTEE

Asst. Supt. of Motive Power, Can. Pacific Ry., Montreal.

Born March 2nd, 1880, in the city of Toronto. Educated in the Toronto Public Schools, the Allandale Public School and the Barrie Collegiate Institute. Started his mechanical career as a call boy for the Grand Trunk Railway at Allandale in September, 1895. From March, 1896, until August, 1902, he served as wiper and fireman for the Canada Atlantic Railway. In Sept., 1902, he engaged as fireman with the C. P. R. operating out of Fort William. Transferred to Moose Jaw in January, 1903, and in March of the same year was promoted to engineer, located at Moose Jaw until Sept., 1909. He was then appointed Road Foreman of Engines, retaining this position until June, 1911, being then appointed to the position of District Master Mechanic with headquarters at Moose

Jaw. From January, 1913, to January, 1915, he was Master Mechanic at Calgary, following which he was appointed to his present position as Assistant Superintendent of Motive Power with headquarters at Montreal.

G. M. WILSON, AUDIT COMMITTEE

Master Mechanic, G. T. R., Montreal

He was born in Belfast, Ireland, on the 5th of October, 1867, of Irish and Scotch parents, and came to this country in 1880. After serving an apprenticeship to the machinist's trade he entered the service of the St. Clair Tunnel Company, in connection with the construction of the St. Clair tunnel, during the years 1889 and 1890, and afterwards was employed by the Jenks Shipbuilding Company at Port Huron, Michigan. After remaining with this firm for a brief period he entered the services of the Grand Trunk Ry. at Fort Gratiot, as a machinist, on the 11th of November, 1890, and subsequently filled the various positions of expert machinist, machine shop foreman, general foreman of the Toronto shops, general inspector of tests over the System, assistant Master Mechanic of the Montreal shops, and was appointed master mechanic on the 1st of Sept., 1917. In the year 1907 he was intrusted with the layingout and supervising the installation of the entire machinery equipment of the main shops of the Western Division at Battle Creek, and on the completion of this work he was transferred to Ottawa to supervise and install the power house equipment in connection with the new station and the Chateau Laurier.

E. E. LLOYD, TREASURER

Auditor of Disbursements, Canadian Pacific Ry., Montreal

Entered the services of the Canadian Pacific Railway as a clerk in the Stores Department at Winnipeg, on Dec. 27th, 1887. Was appointed chief clerk of the Stores Dept. at Vancouver, on Dec. 17th, 1897. Transferred to Montreal on Feb. 1st, 1903, and given the position of Chief Clerk and General Storekeeper. The two departments were subsequently divided and Mr. Lloyd remained with the accounting dept. as chief clerk. He was transferred to the auditing department of stores and mechanical accounts in January, 1905, Assistant Auditor on January 15th, 1910, and Auditor of Stores and Mechanical Accounts in August, 1913. He was appointed to his present position of Auditor of Disbursements on the 18th of March of this year.

JAS. POWELL, SECRETARY

Chief Draughtsman, Motive Power Dept., Grand Trunk Railway, Montreal

Mr. Powell was born in England, serving his apprenticeship with Sharpe & Stewart Company, Ltd., locomotive builders, Manchester. He served in various capacities with different English firms, noteably the Naysmith Co., of Patricroft, Lancashire; the Vulcan Iron Foundry at Earlstown; and also the Lancashire and Yorkshire Railway, Manchester. He came to Canada about 1880 and for the past thirty-seven years has been with the Grand Trunk Railway occupying the positions of leading draughtsman and later as Chief Draughtsman of the company. Much credit is due him for the efficient training of the apprentices throughout the entire system. He has occupied the office of Secretary of the Canadian Railway Club for the past 13 years.

LAYING OUT INVOLUTE TEETH FOR CAST GEARS.

SIMPLE CHART TO ELIMINATE FIGURING OUT CAST GEAR TEETH

The use of gears with cast teeth is common practice in many classes of machinery where absolute accuracy of operation is not essential, but to derive the maximum efficiency from a pair or train of cast gears it is necessary that the profile of the tooth should conform very closely to the desired shape to insure smooth and steady running. The accompanying chart was designed to facilitate the laying out of the teeth on the pattern, eliminating the necessity of calculating the various dimensions for the different sizes of gears and circular pitches. In order to make the chart of practical value the reproduction has been made to meet actual working requirements so that the dimensions can be taken directly off the chart and transferred to the work. However, it might be well to describe the construction of the chart so that those desiring to develop one for their own use can readily do so. It will be noticed that the principle is one of simple proportion, so that the same straight oblique line serves as a basis for the various dimensions of the teeth on different pitch gears.

The base line C-D can be drawn to any length but in this instance it has been given a length of 6 inches, so that the dimensions on the vertical line A-B, drawn perpendicular to the base line, from the 6-inch intersection, will be for a gear having teeth with 6-inch circular pitch. The clearance is generally taken as 1-16 of the working depth, the whole depth being approximately .6866 of the circular pitch. The thickness of the tooth, on the pitch circle in cast gears, is always narrower than the corresponding space. This difference will range from 3-64 inch in small pitches to 1-16 inch in the larger pitches.

An application of the use of the chart is shown above. The teeth on each gear would, of course, be laid out separately, but for sake of illustration they are shown here in mesh, the same principle applying in either gear or pinion. Two essential details are required before the tooth profile can be determined, namely, the length of the generating radius of the tooth face, and the position of the base circle from which the tooth shape is struck. To obtain these, proceed as follows: On the center line K-L lay off the centers M and N of the two gears, this distance being determined by the size and ratio of the gears. When the same has been found, strike off the pitch circles O-P and Q-R tangent to each other and intersecting the center line at the point S. Through this point draw the line T-V at an angle corresponding to the pressure angle desired, either 14½ or 20 degrees—the 14½ degree being the most common pressure angle, while the 20 degree method is sometimes adopted where gears are subjected to heavy duty and give a tooth with a thicker root and therefore a much stronger tooth—the latter being used in this particular instance. Through the centers M and N, and perpendicular to the pressure line T-V, draw the lines M-V and N-W.

We are now ready to lay off the teeth. Owing to the fact that the circular pitch is measured on the arc of the circumference of the pitch circle, it is desirable first to divide the pitch circle into the desired number of equal divisions to suit the number of teeth required. Then from each divisional point strike off the thickness of the teeth. From the center N, and with a radius equal to the distance S-W, describe the base circle 1-2. Now, with a radius equal to N-W, and from the points on the pitch line, giving the thickness of the teeth, as at S-Z, find the generating points, and with the radius N-W describe the arcs that form the faces of the teeth. A prolongation of one of these is shown at 3-4.

The same process is used for laying out the tooth shapes on the pinion, M-V being the length of the generating radius, V-S the radius of the base circle 5-6, the generating points being found as described for the large gear. In every case the arc of the tooth face is drawn from the outside circumference to the base circle, the remainder of the tooth profile being a radial line to the bottom of the working depth. A fillet, as large as conditions will permit, is then struck to form the connection between the flank and the root of the tooth space—usually equal to the clearance.

CUTTING THREADS ON SCREW MACHINES ON BAR STOCK AND CASTINGS

By P. W. BLAIR.

It is a well known saying among lathe-hands and machinists that "if you want a good and perfect thread it must be cut in a lathe."

It is true that a good lathe hand, if he is a first class man, can produce a fine thread on an engine lathe or screw cutting lathe with a special attachment, but it is an expensive operation grinding and setting a single pointed tool until it is at a correct angle and then finishing the piece until it is perfect.

The man next to him not as good a mechanic gets the same or more uniform results about three times as fast by roughing the thread down and sizing by running a die over the thread.

These methods giving good results are slow and expensive. The practical screw machine operator who has given the use of dies a careful study will be able to produce as good results when using a die to complete the thread entirely, if it is made correctly, at a fraction of the cost of lathe work on bar stock or castings. There may be other screw machine operators around him who may fail on the same work unless poor rough torn threads will pass inspection. In the past three years, owing to so many parts being made as component parts of shells, all of which have external or internal threads cut on some portion and the severe inspection and large quantities of above articles being made the cutting of threads has attained a high state of efficiency on screw machines and turret lathes that was unknown before the war.

An operator when given a good die should see that the two most essential things in setting up a screw machine or turret lathe are, first see that the dieholder or dies are in perfect alignment with the work, that the action of the turret slide is central or parallel with this alignment, also see that the die is square with the work, or to be more correct have the die parallel with the work.

It has been also demonstrated that the solid or shell type of dies will give more satisfactory results and threads cut to size better than by using the self-opening style of dies, owing to the slight taper which the latter cut on short lengths.

One of the best methods in testing out the alignment of a screw cutting die or hollow mill die in a screw cutting machine or turret lathe, to find out if it is central, is to give it the following test.

Run the die on to the piece until it fully engages on the threads then slip out the holder, is the easiest test for alignment.

However, if when the chuck revolves with the die on the end of the work it wobbles or runs eccentric something is radically wrong and imperfect threads will be cut.

If the operator is unable to get the die to run true a test arbor with a true thread should be cut in another machine, preferably a lathe. This is then gripped in a collet chuck and the die screwed on by hand; if the die then fails to run true it is a poor die which has been hobbed crooked, that is, when the hob entered the die it went in at an angle, or it sprung or warped in the hardening and tempering operation. By using a die in this condition the resultant thread will be tapered and in bad condition, and as the teeth in the opposite bands do not track, the thread wall will have a series of ridges and steps. Also, as the back edges instead of the cutting edges of the die lands are presented to the work the rubbing of same will tear the threads.

We all know that some new dies will not work satisfactorily at the start and the threads they cut will not pass inspection on munition parts and are quietly laid aside by the operator for fear he will use them. Others work fairly well and occasionally one is found so good that the operator hides it out and runs it to the limit of production.

A great amount of this irregularity and trouble can be traced to the poor alignment of machines.

One of the best methods I employ or pursue on a die when it is new and not giving perfect results is to take a true threaded arbor and open up the die sufficiently to permit it to run on freely then allow the die to close when it will grip the arbor securely enough for grinding. Then in a cylindrical grinder I grind the outside and back of the die true to the arbor and if the die was sprung in hardening I grind the face of the die parallel with the back. If the die and holder are not central with one another the holder is defective, or the hole in turret itself is out of line or otherwise defective.

The majority of screw machines have liners between the lower turret slide and the base for vertical adjustment. If one of these machines are out of line a machinist can readily adjust it or re-align it but the operator should not touch it unless he thoroughly understands what he is doing and has the proper testing tools.

Floating holders help out considerably when the error is slight, the only objection being that they are frequently the cause of dies starting on crookedly and cutting a thread that is not true with the body of the work. A floating holder that is really an advantage on a screw machine is the telescopic type, which permits the die to travel on its work independent of the turret feed freeing it from the drag of the slide, and allowing it freedom to travel on its work and follow its own lead.

These telescopic holders often save considerable time in setting up and will take up defects in some cases but will not of course correct alignment. Screw machines and turret lathes as they come from the manufacturers, generally have good alignment, but they wear and should be frequently tested and realigned by scraping or shimming. This is not only important for good thread work but for other operations also.

Usually if the machines are kept in as good condition as when received from the manufacturers there will be no trouble caused by poor alignment.

However, always test out new dies to see if they have to be fixed at the start and if care is used the threads will compare favourably with threads cut in a lathe.

THE VISCOSITY OF OIL

By M. E.

One of the most used methods of expressing the viscosity of oil is in the terms of the Engler Scale. Degrees Engler means simply the ratio of the time it takes a given quantity of an oil to flow through a standard orifice as compared with the time it would take the same volume of water to flow through. Oil is usually sold, however, on the basis of its specific gravity (generally measured in degrees Baume) and its heat value and moisture content. It is usually assumed that the heavier an oil is in degrees Baume the more viscous it is, but that is not always strictly true. It is not to be regretted, that oil is not specified in terms of specific gravity instead of in degrees Baume, because in any calculations involving the weight of the oil per gallon or per barrel, it is necessary to refer back to specific gravity. Further, the heaviest oil that can be designated on the Baume scale for liquids lighter than water is 10 deg. B. or unit specific gravity. Oils are now being used of 10 and 12 deg. B., and, no doubt, still heavier oils will be used, which will call for two different Baume scales and cause confusion.

LARGE BALL BEARING CONTRACT

The Canadian S K F Co., 47 King street West, Toronto, has received an order for S K F ball bearing hangers for the new shop being erected by the Leaside Munitions Company at Leaside, North Toronto. This contract will cover over 400 ball bearing hangers, and constitutes the largest order for hangers ever placed in Canada. It is significant in the development of anti-friction bearings that they are being universally adopted in the largest plants for all drives, and indications point to their even wider adoption in the future owing to their great saving in power and increase in range of application. Conservation of energy is one of the outstanding problems of the day, and the use of ball bearings is one method of attaining this end.

In a plant of the size such as will be established at Leaside, when a large amount of money is involved, the efficiency of ball bearings must be positively proved and demonstrated because it is possible to purchase similar equipment of plain ring-oiled bearings at considerably less cost. The savings in power and lubrication etc. are very high for ball bearing, and warrant this extra expenditure.

The S K F bearings have been installed in several of the larger Canadian plants, including the Canadian Westinghouse Co., Duncan Lithographing Co., and the T. Eaton Co., all of Hamilton. Also the Consumers Cordage Co., Montreal, the Howard Smith Paper Co., Willards Ltd., and the Laura Secord Candy Works, Toronto, all these being complete installations, in addition to many others.

REGULATIONS FOR DEALERS IN COAL

Regulations regarding the importation, sale and delivery of coal have been issued by the Fuel Controller. Among other things they require that every coal dealer shall post in a prominent place in his office a conspicuous typewritten or printed notice containing a list of prevailing retail prices of all classes and sizes of coal handled by him, including discounts, if any. In calculating overhead charges to determine the price of coal, dealers are required to exercise moderation in the amount they include as their own salaries. In this connection the regulations state, "Salaries and expenses to officers or partners are not to be increased over those prevailing during the year 1914 at a greater rate than salaries in other lines have increased. A dealer may charge his business with his own salary but a reasonable rate only."

Dealers conducting a retail as well as a wholesale business are required to apportion their overhead expenses and fixed charges to each branch, and this apportionment must bear reasonable comparison with the average overhead expenses and fixed charges of dealers who are engaged entirely in retail or entirely in a wholesale business.

A VAST NEW OIL SOURCE

The oil shortage brings into prominence a hitherto neglected source of oil in the form of "oil shale," an organic-matter bearing clay formation, which, when crushed and treated with super-heated steam, yields crude oil and sulphate of ammonia. The prospective development of the huge deposits of oil shale is one of the reasons for the oil land leasing bill now before Congress.

Shale occurs in widespread, thin beds which were formerly sea bottom. These beds are deposits of the clayey matter carried by rivers—clayey matter which, being finely broken up, does not sink readily to the bottom, but after being emptied into the ocean is carried by the current and spread over wide areas. One of the characteristic traits of shale formation is that it very readily breaks into thin layers.

Shale is oil yielding, but not oil bearing. Upon treatment with super-heated steam a chemical reaction takes place which yields crude oil. It must be mined like coal, and at about the same price, so that even with an extensive production of oil from shale there will be no great reduction in the price of oil.

Prof. Russell D. George, State geologist of Colorado, recently said that in two counties of Colorado there was enough shale to make "ten times as much oil as has been produced in the United States since the discovery of oil in 1859."

A new explosive is now being used in South African mines, and is resulting in a great saving of nitro-glycerine, says the "Board of Trade Journal." The shortage of the latter, owing to its use for ammunition, was indeed leading to difficulties in the industry. Hitherto the standard explosive used has been gelignite, which contains 57 per cent. of glycerine. It is now being almost entirely replaced by sengite, which is a gun-cotton explosive specially prepared and put into cartridges for the mines. The ingredients of sengite are more readily obtainable than nitroglycerine, and they are added to gun-cotton. Sengite is not altogether a new explosive but it is new to mining practice on the Rand.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

RESILIOMETER

THE comparative measurement of resilience has always been a matter of some difficulty and in the purchase of such materials as felt, rubber and leather this property becomes of some importance.

The Widney Resiliometer made by the Advance Felt Specialty Co., Chicago, eliminates guesswork in the purchase of such materials and enables them to be purchased according to a rigid specification.

In many cases, the use of the resiliometer will show that material used hitherto for a certain purpose was improperly selected and indicate the proper material to be substituted; or that the specifications of the same material should be radically changed. Felt frequently supplants rubber and leather, simply because it retains its resiliency or "life" longer than any other similar material.

Tone felt, as used in piano making, can be purchased with absolute certainty, according to pre-determined specifications based on tests, thus eliminating one of the greatest uncertainties in piano construction and leading to more scientific methods in tone production.

The use of resilient materials, such as mechanical felt, rubber and various kinds of packings, has greatly increased during the past few years, largely due to the enormous development of the automobile and other engineering industries. It is generally recogized that some definite and comprehensive means for testing the specific properties of such materials is absolutely essential to the intelligent purchase and use of them.

In the case of all resilient materials, and particularly of textiles, the properties and specifications to be ascertained are the exact dimensions, relative hardness, relative resiliency and texture.

The instrument consists primarily of a dial underneath which is a presser foot touching a perfectly level base or platform on which rests the material to be tested. Making sure that the quadrant which holds the weight descending from it is drawn up and held by the spring-catch, the operator lifts up the presser-foot and inserts the material which is to be gauged and tested.

The large dial is graduated in 100 divisions, each of 1-1000 in., so that one revolution of the large pointer or hand is equivalent to an elevation of 1-10 in. of travel by the presser-foot. When the material is more than 1-10 in. thick the needle will revolve more than once around the dial. To count these revolutions a small dial is shown inside the face of the large one, with a pointer or hand that makes one revolution to every four complete revolutions of the larger pointer or hand. This is for convenience in reading.

Suppose the material to be tested is 1-10 in. or .100 in. thick. As the presser-foot goes down the hand may stop at the 100th graduation. This means that the thicknesss is 100-1000 in., which is the thickness of the piece of felt accurately given by the "Widney Standard."

The spring-catch holding the weight is now released and allows quadrant to swing back until pressure is put on up-

RESILIOMETER

per end of presser-foot at the top of dial. At once presser-foot sinks into material, diminishing its thickness, sending the pointer or hand of the dial backwards. When the presser-foot reaches the limit of compression the reading on the dial at that time is taken and compared with the normal or original reading. For instance:

Normal thickness reading . .100 in.
Reading under pressure . . . .050 in.

This means that goods of a normal thickness of .100 in., showing under pressure a thickness of .050 in., are 50-100 or 50 per cent. hard.

If it had not compressed at all, its hardness would have been 100 per cent. (an impossibility with any resilient material). If it had compressed to one-fourth its original thickness, its hardness would have been 25 per cent. If it had compressed to one-tenth of its original thickness, it would have been 10 per cent. hard, and so on.

This gives us the hardness figure of the material in question—a figure henceforth fixed and certain so long as conditions remain the same.

As soon as the above reading has been taken the quadrant is pulled back, releasing weight pressure on the presser-foot. The hand on the dial will begin to advance again. When weight is raised a sufficient height so that weight pressure is released from the presser-foot, the reading of the dial hand is noted. This reading should be taken immediately the weight pressure is released, thereby ascertaining the "instant" resiliency and not gradual return to normal of the material.

Now suppose that the dial-hand (which was at 50 under pressure) advances as pressure is released till it reached .080 in. the resiliency is 60 per cent. For

$80 - 50 = 30$ and 30 is 3-5 of $50 = 60\%$

In other words, the hardness figures showed a compression of .050 in. If the goods reacted to their original thickness they would be 100 per cent. resilient. The amount of reaction in proportion to the compression is the percentage of their resiliency.

Resiliency is sometimes confused with elasticity or "stretchability." Elasticity, as commonly understood, is the capacity of a given material to react after distention or deflection, fairly illustrated by the reaction of a rubber band after being stretched or distended beyond its normal position; or the reaction of a steel bar after having been bent.

Resiliency is one of the most important factors in felt, rubber, and analogous materials, which are bought and used for cushions, bumpers or other mechanical parts. The resiliency of a material is logically and correctly determined by its capacity to recover from compression.

The thicker the material the greater the resistance to penetration.

SAFETY SWITCH

In many steel mills, factories, mines and similar industries where most of the workmen have little knowledge of electricity, it is desirable to use switches having no live parts exposed or accessible in the ordinary operation of the switches or when replacing fuses.

This is fully accomplished in the Krantz Auto-Lock Switch, marketed by the Westinghouse Electric & Manufacturing Company, which is intended for use on main circuits or wherever an ordinary knife switch is applied. The switching parts and fuses are enclosed in a steel box, the cover of which is in two parts, one being screwed on to form a permanent covering for that end of the box containing the switch, and the other part being hinged so as to swing back and permit the renewal of fuses, which are located in this portion of the box. An ingenious latching mechanism makes it impossible to open the cover without first throwing the switch to the "off" position and rendering all fuses and other accessible parts dead. Thus fuses may be replaced at any time with absolute safety. As long as the door of the case is open the switch contacts can not be closed.

By using a padlock, the switch handle can be locked in the "off" position, making it impossible for any one to close the switch except the person holding the key to the padlock. By using another padlock the cover may be locked shut, so that the fuses cannot be tampered with. Either of these padlocks can be used independently of the other so that the switch cover can be locked shut with the switch either "on" or "off", or the switch can be locked in the "off" position with the cover either locked or open.

Contact is made by means of a laminated spring copper brush, double ended, with auxiliary arcing contacts at each end. The outer leaves of the brush are bronze to provide additional spring pressure.

The stationary contacts are of hand-drawn copper and are mounted on slate bases, one of which in the fused switch carries one of the fuse clips, while the other forms the terminal block for the incoming line and is mounted under the stationary portion of the cover.

The operating mechanism is galvanized steel of the toggle type, and is attached to the under side of the stationary end of the cover. This mechanism can be easily removed for inspection by removing several screws.

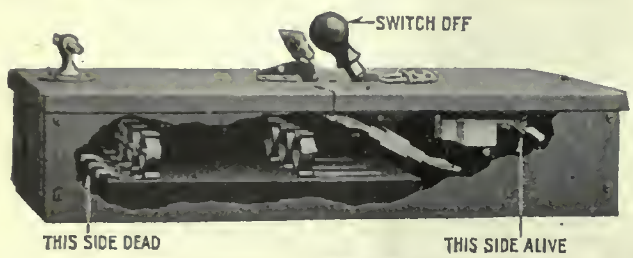
In closing, the pressure between the contacts causes the laminations of the brush to spread apart, giving it a wiping or self-cleaning action.

The double-ended brushes provide a double break, dividing the arc between the two ends, each of which is provided with a separate arcing tip.

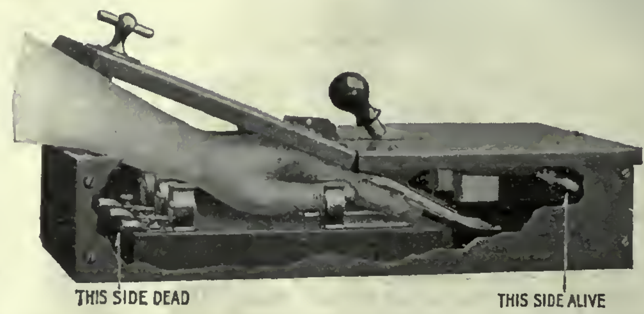
In the closed position the switch is held in positive contact by throwing a toggle over the center. A spring provides a quick-break for opening, the mechanism being independent of the operating handle.

These switches are supplied for 250 500 and 600 volt, for either alternating or direct-current, service, and in capacities up to 2,000 amperes.

The safety features of this switch have been recognized by the American Museum of Safety, which has awarded it a gold medal and special mention.



SAFETY SWITCH BOX CLOSED, SWITCH OPEN.

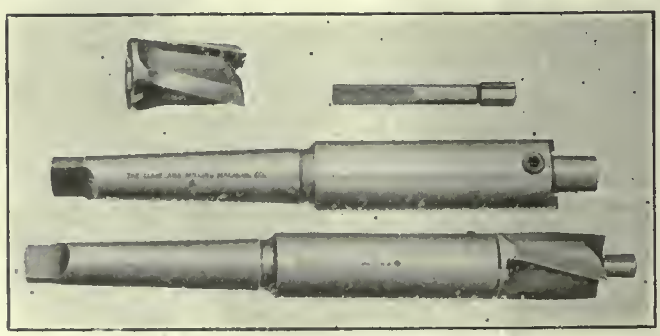


SWITCH. SHOWING IMPOSSIBILITY OF TOUCHING LIVE PARTS.

INTERCHANGEABLE COUNTERBORES OR SPOT FACERS

Counterbores or spot facers are more commonly used at present than heretofore and practically all machine shops use counterbores or spot facers of some description. With this in view the Cleveland Milling Machine Co. have brought out a line of counterbores illustrated in the accompanying engraving.

The shank is made of high carbon steel and is heat treated. The taper is ground concentric with both the driving taper and the pilot hole. The cutter is made of high-speed steel and has a taper hole fitting the arbor and is driven by two face keys so that cutters of various diameters can be used. This construction of cutter makes it possible to easily grind the face of the counterbore true. The pilot is made of high carbon steel, heat treated and ground to fit the hole in the shank and cutter, and it is arranged so that any diameter pilot can be used with any diameter cutter within its range and the change made very quickly. The diameter of the pilot is ground .0015 smaller than the specified size.



INTERCHANGEABLE COUNTERBORE OR SPOT FACER.

FILING MACHINES

The filing machine illustrated herewith has been designed for efficiency, rigidity, and simplicity in construction and operation. A feature of this machine, made by the Newark Engineering and Refrigerating Co., Newark, N. J., is the square shaft which is supported by two extra long babbit bearings making side motion impossible, thereby eliminating the tendency to under cut when working to finished lines. An extra large working platen enables the machine to handle a great variety of work and adjusting and locking screws provide for adjustment of the angle at which the platen is set.

FILING MACHINE

COTTON CLOTH FOR AIRCRAFT

By M. M.

The cotton trade presents many war features. One of the most interesting —and one that is often overlooked—is the provision of cloth for use in the building of aircraft, more particularly of aeroplanes. In this direction the trade has afforded most valuable help to the Allies. In pre-war days the making of aeroplanes fabrics had secured a solid footing in Lancashire, and the government exercised a wise discretion, soon after hostilities began, in acquiring control of the whole output and preventing leakage to the enemy. But prewar production was far from sufficient to meet war needs, and in the last two years there has been a considerable development in the making of fabrics that aeroplane building has asked for. More spindles and more looms have been set to work. Some of the best known and the biggest of the fine spinning concerns are wholly devoted to turning out the yarns, which are spun from high-grade Egyptian and from Sea Island cotton. To make this supply of cotton certain was one of the subjects which the government had in view in deciding to take over the whole of the next crop of Egyptian cotton, a step which had received unanimous approval of the trade.

In application of fine and strong textile to the covering of aeroplane wings cotton has been running a sort of race with linen. There is no doubt that the use of linen, in the past at any rate, has presented some advantages over the use of cotton cloth. Linen is stronger, and has a smoother surface. On the other hand it is heavier, usually weighing 4 oz. per yard as against 3¼ oz. in the case of cotton, an important consideration. One objection to cotton has been that the surface being less smooth than that of linen, there is some interference with the proper application of dope. As to the comparative strength of the two fabrics, one would suppose that cotton cloth, which will stand a strain of 1½ tons per square yard, would meet all demands that are ever likely to be made upon it. However there is no finality in sight in the design and manufacture of cotton fabrics. No one feels more strongly than manufacturers that we have not yet sounded the possibilities of cloth. The more the staple is examined and tested scientifically, the more wonderful does it appear, and the more clearly is it recognized, that the end is not yet. So far, the twin sciences of spinning and weaving in practice have kept fairly level with the demands of the public, but further progress will be made, and it is not too much to hope that cotton cloth will be produced which for aircraft purposes will be of unapproachable excellence and suitability.

At the present time experiments are being carried out with the object of eliminating faults and defects, such as they are, and of providing, a fabric which shall fully satisfy the needs of the aircraft industry. Designers of aeroplanes have laid down certain requirements and the cotton trade is endeavouring to meet them. It must be remarked in this connection that, as the aircraft industry has grown, its needs in the way of essential materials have grown with it and have become more exacting. The chief objects now aimed at are still greater strength and durability, and still greater powers of resistance to wind pressure, with an absolutely smooth and even surface that will not be too absorbent of dope. All this has to be accomplished without any sacrifice of lightness, and without any considerable reduction in the element of elasticity. We have every confidence that the response of the cotton trade will be of the most satisfactory character, and that the aeroplane cotton fabrics of the future will be worthy of a great industry which in the past has scored many triumphs.

MACHINE SHOP HEATING AND VENTILATING

By "Dale"

Considerable difficulty is experienced in arranging for the heating and ventilating of the single storey sheds with saw-tooth roofs now in universal favor for light machine shops. The wide expanse of surface exposed to the weather in such buildings makes the task of maintaining a comfortable working temperature difficult on cold days, and while roof ventilators and fans afford adequate ventilation in summer, they are invariably put out of action in winter on account of the excessive down draught of cold air, whereupon the air in the centre of the shops becomes stagnant and impure. But satisfactory hygienic conditions are essential to the maintenance of efficiency; hence some method must be devised to supply warm, fresh air in the winter, and cool air in the summer to all parts of the building. A good arrangement has been in work for two years past in a well known English plant at Birmingham. It consists of a number of cupola-shaped heaters (four in this particular case) distributed about the shed, each of which draws air by means of a 15-inch motor-driven horizontal propeller fan, located at the b- down inlet pipe protruding through the roof, passes it through a battery of steam pipes, and ejects it at the floor level, whence it rises and circulates through the building. The down pipe is fitted, just below the roof, with a swinging damper which can be moved so as to block the admission of outside air and allow the warm air from inside the shop to be passed and repassed through the heater. This is very beneficial on cold mornings, as it enables the air to be raised to a suitable temperature in a short time, whereupon the damper can be moved back and the temperature maintained with the cold air outside passing through. This feature is a distinct improvement on many other types of heating apparatus. The steam is supplied to the heaters from a vertical boiler 9 ft. high by 3 ft. 9 in. diameter (which if worked at 80 lb. per sq. inch, is capable of serving eight heaters in the coldest weather) through 1 in. branches from the main steam pipe, and is trapped at the outlet with a steam trap of the float type, in order to prevent the passage of uncondensed steam. The condensed steam, after leaving the trap, is forced along a ¾ in. pipe, past a check valve, into the main return pipe, which conveys it to the boiler feed.

The legs of the heater are utilized as a means of connection to the stem and drain pipes. Valves are fitted to both pipes of each heater, so that one can be out for repairs without disturbing the others. The temperature can be varied by altering the steam pressure, by varying the quantity of steam passing through the steam valves, or by means of the motor regulator, the latter being arraned to give four different speeds. During the warmer weather, when it becomes unnecessary to use the heating part of the apparatus, the fans are used for ventilating only. The impure air escapes through the interstices in the doors and between the valley gutters and the lower purlin on the glazed side of the roof. By reason of the pressure inside the building being slightly greater than that of the atmosphere, all leakages are from the inside outwards, and hence draughts are prevented. The cost of this method of heating and ventilating compares very favorably with any proprietary system, and at the same time meets all the requirements of a modern heating and ventilating plant.

It has been found possible mechanically to work tungsten containing a considerable amount of tungsten carbide when the carbide was made separately, powdered, and added to the tungsten powder before pressing. Tungsten ingots containing tungsten carbide made up in this manner may be mechanically worked when the carbon content is far in excess of that necessary to make the tungsten brittle ordinarily. When added in this way the tungsten carbide does not surround the tungsten grains.

In response to requests from the Ministry of Munitions and the Department of Scientific and Industrial Research, and in conjunction with the British Chemical Ware Manufacturers' Association and the British Laboratory Ware Association, arrangements have been made, with the aid of the Ministry of Munitions, for testing graduated glassware at the National Physical Laboratory on a larger scale than has hitherto been possible. The conditions of test, and scale of charges, are given in the test pamphlet of the Metrology (Glass Testing) Department, copies of which may be obtained on application to the Director, National Physical Laboratory, Teddington.

Vol. XX. AUGUST 15 No. 7

The Position of the Scrap Metal Trade

ONE of the changes that has come over at least one line of business as a result of war conditions has been the lifting of the scrap metal business out of the ordinary class, and placing it in the very extraordinary division.

Our first impression of the scrap business may have been gathered from the time when we used to spend Saturday afternoons out looking for old metal and bones, for which there was always a few cents recompense in any town or city in the country.

Very few outside of the trade know the tremendous amounts that are involved in the scrap transactions that are going on at present. And were it not for the fact that the Munitions Board steps in and takes over all the turnings and cuttings from the munitions shops now, there would be a volume of business in this line that would be hard to credit or believe.

The little old rickety wagon that wabbles around picking up the scrap iron is certainly coming into its own with a vengeance. It may be that in the near future we will see traffic cops giving it right of way over every other sort of vehicle in the congested area, and the gentry in charge of them wearing medals that will make iron crosses look flat, tame and uninteresting.

A decision that was made last week in a case that came up in one of the big steel and iron centres of the United States has a greater bearing than the simple giving of the decision. It was, in effect, that those working in scrap yards, sorting and handling second-hand metals, were engaged in useful occupations. There were a lot of people who had a habit of looking down on the man working in a scrap yard as following a poor game. There may have been nothing very romantic about the occupation, and it may have been from sheer necessity that the man entered the occupation. Well, allow for all that, but look at the standing of the business now. When other lines, that in ordinary times are apt to try for a top rail on the fence, and plume themselves as being very legitimate and useful businesses, are being closed down by the War Board as non-essential, the sanction of the same board is given to the men working in the scrap metal yards. Quite a change, isn't it?

The war is cutting a lot of new swaths that are hurting the feelings of not a few people. No man likes to have his organization dubbed by the authorities as non-essential. He has been in the habit of imagining that his little undertaking was the most essential concern in the country, and that if anything happened to it, panic, widespread an dterrific, would certainly come and camp in our midst.

But his concern has been passed by. The authorities have put the thing in the sieve of war need and it has gone through the meshes. The man at the head of it has been told that he can't enter the market for iron or steel, and he will have to close up until after the war or do something more necessary in his shop. There is bound to be a great old trail of punctured pride, hurt feelings and ruffled dignity in the land while a batch of these non-essentials sit down at the side of the road and watch the scrap metal cart go by in the procession approved by the Government.

Real Economy in Burning All the Coal

THERE seems to be no end of advice given officially and otherwise to the Canadian public this year in regard to the necessity of saving coal, both in power plants and in the heating plants for the home. Occasionally there are some suggestions in regard to the proper methods of firing, and the securing of perfect combustion that have some real value, but there is a great deal of wasted and misspent effort in the advice given as a general thing.

Real results are going to be secured in making it certain that the greatest possible amount of heat is secured from the fuel we burn.

A steam engine is a waster at best. It is considered quite satisfactory to use 20 per cent. of the actual steam value delivered to the ordinary engine, and in many cases the figure will be well below that.

Boiler efficiency is another matter that has much to do with the amount of coal burned and the relative amount of heat obtained from it. There are, of course, boiler plants where as high as 80 per cent. of the heat in the coal will be secured, but that is above the average. Perhaps a figure around 60 per cent. would be much nearer.

There should be an effort made to induce power plant users to go ahead and introduce in their premises appliances that will make it certain that they will secure the maximum amount of heat from every ton of coal that goes into their furnaces.

Very little is going to be gained by simply keeping up a harangue that the people should burn less coal. That will probably result in decreased efficiency all round.

The big drive should be to see to it that we burn coal instead of letting a large percentage of the combustible material drift up and out of the smokestack.

AN extraordinary story of a boy's enterprise was related at London Sessions, when Robert Scott (17), engineer, pleaded guilty to receiving stolen tools. Mr. St. John Hutchinson said accused was undoubtedly a lad of exceptional ability with a future before him. He left the Hugh Myddelton School when fourteen years of age, and entered prosecutor's employ, showing such engineering skill that at fifteen he was earning 35s. a week. While still that age he and another boy took a back room and commenced making screws and nuts. The partner, reaching eighteen, had to join the army, but Scott continued working, and was so successful that he was able to take premises at £130 a year and employ eleven men and eight women. He had saved £400 and spent it on machinery, and a further sum saved had been invested in war stock. He now held large contracts with the Government relating to aeroplane work. Sir R. Wallace, K.C., said that all must regret that the lad had used his marvellous gifts in such a way. He would give him another chance and bind him over to come up for judgment if called upon.—Birmingham Post.

* * *

AMERICAN officers in Canada are well pleased with the way Canadians are handling their orders. They started out to make this place the granary of the Empire, but they simply can't keep from sticking a machine shop in between the farms.

SPECIALIST IN FINE SCIENTIFIC TOOLS

From His Early Youth, Robert Dawson has Been Associated With the Manufacture of Accurate Recording Instruments

CHANCE, as a factor of industrial achievements, is rapidly being eliminated from the field of engineering, as the manufacture of fine scientific and mechanical instruments of the most modern type now assures a degree of accuracy never attained in the past. Until very recently work of this character had received little attention here in Canada, but early in the present year

ROBERT DAWSON

the engineering firm of Peacock Bros., Montreal, decided to open a new department for the repair and maintenance of the many recording instruments passing through their hands.

One of the essential considerations in connection with the efficient operation of such a department was that of securing a man suitably adapted, and with the necessary knowledge of such instruments, to carry on the work successfully. The firm, however, were fortunate in acquiring a man whose life has virtually been spent on a class of work that specially fits him for this previously neglected branch of Canadian industry.

Robert Dawson was born at Edinburgh, Scotland, of Scotch parents, but when two years old was brought to Canada, where his father secured a position with Messrs. Ross of Montreal, who in the past seventies were engaged in the manufacture of all classes of civil engineering instruments. When young Dawson was about seven years old the family returned to Scotland but shortly after migrated to Dublin, Ireland, where the father secured employment with the instrument firm of Yeates & Son. Subsequently, however, the senior Dawson started in business for himself, so that the early years of the "boy's" life were associated with the work that he eventually mastered. Much of his early training was acquired at the Dublin Technical School where the education proved of great assistance in his practical efforts.

After putting in several years of "spare time" with his father, Bob entered the services of Yeates & Son and gained a wider experience in the manufacture of all kinds of scientific instruments. After several years with this firm he engaged with Dobson & Curtis, remaining with them until they went out of business, afterwards entering the employ of Sir Howard Grubb at his astronomical works, Rathmines, Dublin. Sir Howard Grubb is famous all over the world as a manufacturer of large telescopes and other observatory equipment, and under his guidance Mr. Dawson helped to build instruments for Australia and South Africa.

Gains Further Experience

His next position was with the firm of Thos. Mason, Dane St., Dublin, where he had charge of the laboratory for testing and adjusting all kinds of measuring instruments, atmospheric recorders and all kinds of civil engineering instruments. While associated with this firm his work kept him in close touch with many of the large colleges of Ireland, notably Trinity College, the College of Science, all the colleges of Dublin, and many others throughout the country. In this position he also became expert in the moving picture business, Messrs. Mason having the largest connection in Ireland in the optical lantern moving picture machine trade. After acquiring considerable experience with this firm, Mr. Dawson opened a moving picture theatre of his own, but gave it up after a short period and came to Canada in 1913.

He Comes to Canada

His first position here was with the Gowland Optical Co., of Westmount, where for nearly five years he was engaged on fine machine work almost continually, the company manufacturing tools which were extremely accurate for grinding and polishing optical lenses. Upon learning that Peacock Bros., of Montreal, were contemplating the opening of a new department for the repairing of all kinds of scientific and recording instruments, Mr. Dawson made himself known to the firm and his past experience and general qualifications were such that he was engaged "on the spot" to take charge of the new department.

Prior to January of this year it was practically impossible to have repairs of this description made in Canada so that it was necessary to send the instruments to the States for overhauling and repairs, entailing not only an additional expenditure of money but long delay in getting equipment returned.

In addition to their regular engineering lines the impetus given to marine development has increased the scope of Peacock Bros.' activities and Mr. Dawson's duties have required his presence on many of the vessels plying in and out of the port of Montreal, for the purpose of repairing and adjusting many of the recording instruments used for navigation.

Mr. Dawson in his department specializes in the "Foxboro" type of recording instruments, he having made an extended visit to the works at Foxboro, Mass., to acquire the essential knowledge required for efficient service. Many other types of equipment reach him for repairs and are promptly turned out in working condition.

Mr. Dawson in commenting on the value of technical newspapers, says, "These papers are of vital importance to anyone working at a trade, as they enable one to keep in close touch with all the most recent developments and improvements in machines and equipment."

We never knew very many people who got into much trouble minding their own business.

* * *

IT'S an awful sensation for a man to go away for a couple of week's holidays and then come back and find that business has gone along splendidly during his absence.

* * *

SOME of the women who have been working in machine shops for the last couple of years, will, when they return to domestic life, be persisting in pouring oil on the bearings of the egg-beater, and adjusting to fine degrees the mechanism of the coffee grinder.

MARKET DEVELOPMENTS

Much Harder to go Into the U.S. Steel Market

Production of Steel is Gratifying, but it Cannot Keep Pace With the Demand For Plate—Scrap Dealers Classed as Being in the "Useful Occupation" Class by United States Courts

A finding recently handed down by one of the courts in Pittsburg gives an interesting sidelight on the tendency of war decisions, and the out-of-the-ordinary things that happen when they get down to deciding between essentials and non-essentials. The scrap metal industry is little understood in many centres. The scrap cart is not looked upon as having a very pronounced standing in the commercial category. But the U. S. courts have ruled that men employed in scrap yards are working at "useful occupations," and are given such recognition by the war authorities. And this is happening right at a time when a large number of industries that in peace time imagined they were very essential are being denied access to the steel and iron markets.

Some of the more recently placed contracts in Canada are getting well under way and production will be secured in a short time. The American officials in Canada are well pleased at the way in which the work is going on here, one of them being authority for the statement that the reports from this district reaching Washington were second to none in any part of the continent.

It is becoming harder to secure steel in any shape from the American mills. There is a tremendous demand there for plate for the Emergency Fleet, and the figures advanced seem to increase every time there is a fresh announcement made of the requirements of the situation. Nor does it seem to make much difference who is the seeking party in Canada. For instance the firm contracting for the boilers to heat the Parliament Buildings at Ottawa have been held up for a good many weeks on account of their inability to secure boiler plate. An attempt is now being made by a Cabinet Minister to have this plate included in the Canadian allotment for the month and released immediately.

There is still a large volume of business being done in machine tools and supplies. Some of the firms here are having a little difficulty in tooling up for new contracts, not being able to get deliveries on all the material they require. The demand for high speed steel is very active again, and some lines are not securing as rapid deliveries as might be desired.

Production figures from the large producing centres in United States show that figures have kept up remarkably well during the hot weather. There is always a falling off during the excessively hot period, but this tendency has been less marked this year than formerly. No doubt the urgency of the situation has had much to do with the way in which the men in furnace and rolling work have kept production up to a high standard.

Many of the mills report a good supply of heavy melting steel in the yards and on the way. In fact, some of them are so well supplied just now that they are not taking on further supplies. There is still a scarcity of good machinery scrap, and some of this would be very acceptable in a good many foundries just now.

EXTREME HEAT OF WEEK AFFECTS OPERATION AND PRODUCTION

Special to CANADIAN MACHINERY.

MONTREAL, Que., Aug. 13.—Activities in almost every industry have been more or less affected by the exceptional hot wave that has been prolonged during the past week. Production in many lines has fallen off and in some instances sections of plants have been been forced to operate on shorter time to relieve the men from the extreme heat. Another feature that has a bearing on the general conditions is the holiday season that invariably affects business. Inability to secure materials has tended to disorganize business, but under the circumstances operations are proceeding with reasonable regularity.

Steel Still Acute

Tension in the steel situation is still very pronounced and no relief has been shown in the obtaining of material from the mills. Nothing but oessential requirements will receive cnsideration from the War Trade Board and therefore domestic trading has been virtually eliminated. Manufacturers here are still seriously handicapped for lack of sufficient steel for capacity operations, and this condition is more pronounced in the shipbuilding industry than in any other, plates being the material that is the hardest to obtain. As may be expected the extreme warm weather has been and will continue to be a detrimental factor to production, as workmen are frequently unable to keep the pace that is possible in cooler weather. The situation here maintains its acute condition, and dealers do not anticipate an early change for the better. With few exceptions the market is held very firm and prices are unchanged.

Good Demand for High Speed Steel

As a result of the recent activity in the manufacture of munitions the requirements for high speed steel have been on a scale equal almost to that of a couple of years ago. Difficulty is still experienced by dealers here in obtaining supplies of steel from the makers, especially where the source of supply is in England. One dealer reports that delivery from Sheffield cannot be assure under a period of from 6 to 9 months. Sizes that are in heavy demand can virtually be disposed of on the very day of their arrival. Consumers show some reluctance to purchasing sizes larger than they need, as in many instances the surplus must be wasted, and at $2.25 per lb. this is very often a serious factor.

Metals Generally Quiet.

Apart from the nervousness that still prevails in the tin situation the metal market has developed no features of special interest. Copper has steadied following the assurance that the existing price will prevail until November the 1st. Tin attained a record high during the past week, but is again at the level of the past several weeks. The other metals are comparatively quiet and price quotations are unchanged.

COPPER—The situation has taken on a steadier tendency owing to the announcement that the newly revised price will be extended to Novmber the 1st. Metal is still hard to obtain owing to the abnormal requirements both here and in the States. Prices here are very firm at 31 and 32 cents per lb.

TIN—The market is still in a very acute stage, this having been additionally emphasized by the recent advance to uprecedented price on the Singapore market. This peak quotation, however, has since declined and the situation is again back to its previous position of uncertainty and nervousness.

Dealers here are still having difficulty in securing metal, but are able to supply the most essential needs of their customers. Local quotations are very strong at $1.25 per lb.

Holiday Season Affects Tool Business

In common with all general business the machine tool activity has been passing through a quiet period as a result of the warm weather and the absence of the officials responsible for the placing of orders for tools and equipment. The decline in the enquiry for new machinery for shell making would appear to indicate that the bulk of the tools required for this purpose have already bbeen ordered. Many of these tools, however, are still waiting to be delivered but the pressure on the machine bulider is at present so great that definite date of shipment is very uncertain. This condition is not conducive to maximum steel production and where used equipment can be found available the same is often temporarily acquired to assist production. The general demand for machine shop supplies continues very good but frequently the same condition of uncertain delivery applies to this as to the heavier tools.

Scrap Very Quiet.

The scrap situation has been somewhat affected by the warm weather and the holiday season and general trade is very quiet. Dealers report little doing, the bulk of the business being of a local character, small lots of odd material coming in from the country. The present demand is far from encouraging, but dealers here anticipate a renewal of activity within a few weeks. Dealers here are rather reluctant to stock up when the demand is so light as consumers are only buying to cover their immediate requirements. A few changes have taken place in the week's quotations, notably in copper and brass. Copper is now ranging from 21 cents for light to $25.50 for crucible and heavy. Light brass is now quoted at 10 cents, being a little easier than last week. An advance of $2 on stove plate puts the current price at $26.00 per ton.

POINTS IN WEEK'S MARKETING NOTES

Inability to get boiler plates from U. S. points has held up boiler work for the Ottawa Parliament Buildings. One of the Dominion Ministers is trying to get the amount included in the Canadian allotment.

—

The price of plate is practically fixed at $10 for Canadian points. Before the war sales were made at $2.50, and dealers claim they made more money at that sale price.

—

Canadian authorities now recognize $7.50 f.o.b. mill as the selling price for steel plate.

—

A finding in U. S. courts places workers in scrap yards in the category of those who are following a useful occupation.

—

Machinery scrap is much in demand, but reports have it that some of the mills are well filled up with heavy melting steel—so much so that no new purchases are being made.

—

American officials attached to the Imperial Munitions Board here are well pleased with the production records they are securing here.

—

U. S. experts are not certain whether it would be good policy on their part to try to build new blast and open hearth furnaces. At present all war activity practically rests on the ingot production.

—

The shipments of Lake Superior iron ore that are passing down this year are breaking by a large margin all previous records.

—

Reports for the past few months show that United States railroads are getting a much higher car-mile rate than formerly.

—

Pittsburgh reports that the decrease in the hot weather is much less marked this year than is usually the case.

CAN'T GET PLATE TO MAKE THE BOILERS

And So Work on Canadian Government Contract Has Been Held Up For Some Time

TORONTO.—Some nice orders are being handled by machine tool houses in Toronto—orders that run into a good many thousand dollars. Of course the great bulk of it centres around the war contracts. Some of them are not altogether in the category of war business, from the standpoint of munitions. For instance, Fairbanks-Morse have just completed the placing of a good sized order for the Aviation Department of the Imperial Munitions Board. This is for the fitting up of an engine repair park for the flying camps in this district.

Dealers are getting better deliveries from many of the shops where they had placed contracts, especially for single purpose machinery, and on this account deliveries of shells will be hastened to that extent. One of the officers in the American section of the Imperial Munitions Board expressed himself as well pleased with the work of the Canadian war contract shops. Discussing the matter with a representative of CANADIAN MACHINERY the officer in question intimated that the reports that were sent to Washington regarding output and progress were not outdone by any report reaching the American capital from the various branches in the republic. He stated that the work here was being well done, and that they were receiving every assistance from the officers of the Imperial Munitions Board.

The steel situation does not improve. It is becoming a harder matter to secure material from the States, and the fact that a person gets a license does not mean that the goods will be delivered. In fact this shortage of material is causing the holding up of a good many enterprises in this district that would run into the thousands and millions.

Can't Get Supplies

The big contractor is suffering with the little fellow. For instance the firm that is making the boilers for the new Canadian Parliament Buildings at Ottawa has been held up now for almost two months because the plate cannot be secured from the rollers to permit the firm to go ahead with the work. As the season is getting well advanced some of the authorities are anxious to get progress with the work, and one of the Canadian cabinet ministers has taken the matter up in an effort to have the Ottawa order included in the Canadian allotment. As one of the Toronto dealers put the case to-day: "Our experience is that it is not much of a trick to get a license and a priority certificate. Once a person is armed with all that paper he imagines when he approaches the rollers that it will be simply a case of going in and looking over the stock and filling your order from it. But you find that your man at the mill is not very much impressed with all your documents. He tells you that he will place the order on his books, and he will also tell you that there are a whole lot of people in possession of just the same sort of official documents that you counted on to move all obstacles out of the way for you. Our experience is that priority orders and licenses are not nearly as formidable and as powerful as one might think."

Some Tubes Coming In

One Toronto firm got in a good sized shipment by lake of boiler tubes. They were of the seamless variety, and there seems to be more of these on the move than of the lapweld. There has been a decided shortage of the two-inch size, but apparently there has been some relief in the supply of skelp, which has been blamed for some time past for holding up the finished tube.

As intimated in these columns of last week, prices on galvanized sheets have advanced 50 cents per hundred, and there has been an increase in the black sheets, but hardly to the same extent.

Plate Price Agreed On

The price quoted for plate for some time past has been around the $10 mark, and it seems likely that this will continue as the basis of trading for some time to come. Although no announcement has been made, it is generally understood that the Government and the jobbers have come to regard the $10 per hundred price as a fair point for the selling of plate. A few sales are made slightly under that point, but not many. The Government has sanctioned an f.o.b. price of $7.50 at Canadian mills and another cent can very well be added before the material is placed in warehouses here.

It is interesting to recall, in view of the $10 price that it is not very many years ago since plate was quoted at Pittsburgh around the $1.05 mark. Sales were made from Toronto warehouses right along around $2.50, just one-quarter of the present price.

Recognizing Scrap Workers

An incident in the Pittsburgh district recently has an interesting bearing on the scrap metal situation. The War Industries Board has given recognition to those working in scrap yards that they are engaged in work that comes under the heading of "useful" and approved of by the war authorities of the republic. This is done at a time when supplies are gradually being denied to many concerns that in times of peace would be inclined to look askance at the scrap metal dealers.

There is not a very great amount of trade passing in the scrap yards. Dealers here state that the mills are well filled up with heavy melting stetel, and they are to a large extent rather at a loss to know where it is coming from. One of the dealers stated this morning that a rolling mill had almost 800 cars of scrap in the yards and on the way, and were refusing to take on anything else, claiming it was not graded up to their requirements. There is still a shortage of good machinery scrap, and any of the yards here would be glad to take on a lot of business in this direction. Prices are tight just now, and those in the trade state that it is not possible to get a cent over the market price.

Still All War Business

The dealers here are still handling big orders. Most of them can be traced directly to war business. There is nothing in this to indicate that other lines have gone out of action, but it is the result of war pressure, and the unsatisfied demand for supplies. Some of the shops in Toronto that are handling the 9.2 orders have started work on the first one or two operations, but little progress has been made as they do not wish to fill up their shops. The desire is to get a steady flow through all operations at the same time. There is delay in some quarters on account of not being able to secure tools on the time notice given. High speed goods are still in big demand with prices unchanged.

COMBING COUNTRY FOR SCRAP BRINGS ONLY SMALL AMOUNT IN

THE importance being assumed by the scrap metal situation at the present time would almost warrant some better name being coined for this trade. Certain it is, that never before in many years has there been such a diligent search for the elusive second-hand metal as is going on all over the country at the present time. Foundries, finding themselves short of pig iron, are making that shortage up in many cases by introducing a much larger percentage of scrap than is usually the case. Open hearth furnaces are also on the market all the time for scrap. Reports from U. S. points are as follows:

Pittsburgh.—This great steel centre, it is estimated, consumes about 44 per cent. of the entire scrap output of the country and against this there is produced here only about 24 per cent. of the amount, so that even under ordinary conditions it has to depend upon outside sources for a good 20 per cent. of its supply. The trouble here just now is that these outside sources cannot be drawn upon as they are making use of all their own scrap. Although shell steel turnings are being made in greater quantity than ever before, it must be remembered that they are also being consumed as fast as they are produced.

Boston—The labor situation has not improved at all in this district and it is very safe to say that the labor shortage is making it impossible for the yards to handle one-half of the business that could be carried by them.

New York—A continuous and persistent demand has forced up the prices on stove plates and grates to the maximum limits of the market. The intensely hot weather of the past few days has had a telling effect on the volume of business carried and a number of the yards have been curtailing operations to a considerable degree.

Philadelphia.—A ruling that has been made by Provost General Crowder regarding employees of scrap yards will have considerable interest all over the country. The point was raised as to whether employees of these places would be considered as working at essential or non-essential occupations and the ruling of the authority in this case is that those working in scrap yards are carrying on business that is regarded as being essential and is placed in the class of useful work. There is a very keen demand here for all grades of scrap and this tends to keep supplies scarce and also to limit the number of sales.

Buffalo—Many of the consumers here are handicapped by a great shortage of labor and a number of the dealers are in even worse shape. As a matter of fact there is not a very great deal of scrap in the dealers' yards, as the most of it moves out almost as quickly as it arrives.

Cleveland—A number of the dealers here are wondering what will happen on October 1st, for on that date it is anticipated that the scrap and steel prices will be revised again for the next three months.

Youngstown—A very large number of the dealers here are short at the present time and are fearing that an increase in prices will come, as they are hearing constant complaints from the producers that the present prices being paid are too small for them to do business on. A man who has scrap to sell here at the present time can very easily find buyers, but the buyers in a great many cases find it very hard to find the sellers.

Chicago—The usual sources of scrap here are not yielding as much material as formerly and the railroads are doing comparatively little to help on the situation. In nearly every line prices are advancing gradually and nearly all of the items will be at the Government maximum shortly.

Cincinnati—There are two things that stand out prominently in the market situation here right now—one is the increased demand and the other is the decreased supplies of scrap. The dealers are not making predictions as to what the outcome of this situation may be.

St. Louis—Dealers here are making every effort to secure increased tonnages but they are rewarded with only indifferent success. Very little of the railroad scrap ever reaches the yards now as there seems to be a disposition on the part of the officials to deal direct with the consumers.

Clutches.—Hill Clutch Co., Cleveland. June issue of "Hill Clutch Equipment." Mentions an installation of clutches and bearings at the Baker R. & L. Co. for the testing of automobile engines. A description of the equipment employed is presented, supplemented by two illustrations of the engine testing section and others of the bearings and clutches used.

HABIT OF "TAKING HOLIDAYS" INTERFERES WITH PRODUCTION

Special to CANADIAN MACHINERY.

SYDNEY, N.S., August 14.—The contract for the excavation and foundations of the new plate mill at the Dominion Steel Company's Sydney plant has been let to the Bate-MacMahon Co. and work on this contract was commenced on the 7th August, which is stated to coincide curiously with the date when the first sod was turned for the plant itself, namely 7th August, 1899, or nineteen years ago exactly.

The plate mill itself is being furnished by the United Engineering Company of Pittsburgh. The Dominion Bridge Co. is furnishing the structural material for the mill buildings.

While no exact date can be given in connection with construction work under present day conditions, it is thought that the plate mill may be in actual operation before Christmas, 1919.

Taking "Holidays"

The employees of the Dominion Steel Company have on two successive Sundays taken a "holiday" as a protest against the non-granting of their wage demands in full. In May, a Royal Commission considered this matter and made certain recommendations which the Steel Company fulfilled to the letter, and in addition gave further substantial increases to classes which had not been included in the recommendations of the Royal Commission. Still further increases have been promised, but nevertheless the employees have taken the extraordinary course mentioned. A "holiday" on Sunday is just as injurious to a continuous process operation as a holiday on any other day, and as a result the production of the plant has been interrupted in each instance for half the week following the "holiday." The proceeding is a profitless and inept one on the part of the workmen, for it reduces their earnings, both as to day rates and as to tonnage earnings, and of course, it has the still more important consequence in these days of reducing the production of munitions steel. The idea of taking this "holiday" on a Sunday is a subterfuge, and not a particularly subtle one at that.

Pro and Con Argument

A certain number of the workmen object on conscientious grounds to working on Sundays, but as was proved very clearly before the Royal Commission, a still greater number prefer to work on Sundays, and indeed to get in as much overtime as possible. The real desire of the workmen is to be paid time and a half or double time for Sunday labor, which, in a continuous process, merely amounts to a demand for a general increase in wages. The long week-end shift which is called for every alternate week in the case of twelve-hour men is objectionable, but the alternative is a serious one. It is nothing more than the adoption of a three-shift system covering the 24 hours in lieu of a two-shift system. Short of this change in system, there is no possible means of avoiding Sunday work, or the long week-end shift every fortnight. Some day this revolutionary change may come about in steel works, but the present time of labor shortage and extraordinary demand is not the best moment to choose for enforcing such a change.

The Attitude of Ottawa

The attitude of the Labor Department at Ottawa has recently been to put most of the onus for labor disputes upon the employer, it being apparently the idea at Ottawa that nothing is easier than to raise wages and shorten hours because trade conditions are so prosperous, but here is an instance where the employers have far exceeded the recommendations of a judicial body appointed by the Government to investigate and recommend an equitable settlement, and while recalcitrance on the part of the employer would doubtless have been quickly dealt with by Ottawa, when the fault lies with the workmen, the Government is apparently unable to take any effective action.

According to the agreement between the Amalgamated Mine Workers and the coal operators in the Sydney district, an advance in wages becomes effective 1st July, calculated on the increase in the costs of living which are supposed to have taken place between the 1st of January and the 1st of July. There is some difference of opinion as to the true amount of this increase, but there will be no difficulty in arriving at a settlement. The company has offered an increase of 20 cents per day to all workmen, plus certain bonuses to the men at the coal face, and it is likely the offer will become the basis of the settlement.

FORD TO DOUBLE HIS TRACTOR OUTPUT

Many Big U. S. Plants Hasten to Turn Over to Making War Materials

Special to CANADIAN MACHINERY.

NEW YORK, Aug. 14th.—War work is absorbing manufacturing capacity of the country to a greater extent than ever before. In the last ten days, several important industries that heretofore have kept within the limits of their ordinary work, have turned with avidity to the manufacture of shells, airplane motors and other munitions which go directly to the army and navy. The Government has distributed several large orders for trench mortar shells, illuminating projectiles, gun parts, mechanisms and airplane motors.

Cars to Plane Motors

The Pierce-Arrow Motor Car Co. has come into the market for several hundred machine tools which will be used in converting its Buffalo plant, previously used in the manufacture of pleasure cars, into a factory for the production of airplane motors on a large scale. It is planned eventually to manufacture fifty Hispano-Suiza airplane motors a day. It is hoped by January 1st to turn out thirty motors a day.

The U. S. Cast Iron Pipe & Foundry Co., which has found much difficulty recently in obtaining enough pig iron to keep its plants operating 50 per cent. of capacity, has turned to war work, having accepted a large contract from the Government for 6-inch cast iron and steel shells upon which some external machine work will be necessary. The orders will be executed at the Burlington, N.J., and at the Alabama shops at Birmingham and Bessemer.

The Laclede Gas Light Co. of St. Louis, has accepted a large contract for projectiles and is equipping a factory which will duplicate that now being constructed by the Scullin Steel Co. Each of these plants will have a capacity to produce 300,000 150 mm. and 240 mm. shells a month.

The Savage Arms Corporation, Sharon, Pa., is buying additional shop equipment to increase output of guns and is now making extensions to its Isaac Sheppard & Sons plant at Philadelphia and at its Defiance Manufacturing Works at Somerdale. The Midvale Steel & Ordnance Co. has finally awarded its large contract for cranes for the Nicetown plant, equally between the Morgan Engineering Co. and the Alliance Machine Co. of Alliance, Ohio.

The Bureau of Supplies and Accounts, Navy Department, has put out a list of sixty-four machines which are to be purchased and installed in the Washington Navy Yard. Specifications cover 24 drill presses, fifteen milling machines and nine boring machines. The quartermaster's department of the army is still in the market for twelve semi-portable bridge cranes which are to be established in the mammoth stores now being constructed at Boston.

Railroads and railroad equipment manufacturers are making some purchases of shop equipment for the building and repairing of motive power. The Lima Locomotive Works, Lima, Ohio, is enlarging its plant to give it capacity to produce fifty instead of thirty locomotives a month. The Norfolk & Western R. R. has asked for bids on forty machine tools and the Nickel Plate has begun to purchase against the revised list of tools which it originally put out last February.

Shipbuilders continue actively in the market. The Federal Shipbuilding Corporation has bought a large amount of hydraulic machinery in Philadelphia and also ordered several additional cranes for its Kearney, N.J., shipyard. The Downey Shipbuilding Corporation has bought sixteen machines to be installed in its machine shop at States Island. The Sun Shipbuilding Co., Chester, has bought more cranes and machine tools. The New York Shipbuilding Corporation has also made additional purchases of fabricating machinery. Henry Ford & Son are preparing to enlarge their plant in Dearborn, Michigan, in order to produce 150 tractors a day. The Wisconsin Gun Co. has purchased machinery which will double its capacity.

FURNACES ARE NOT TURNING OUT ENOUGH PIG TO SATISFY MARKET

A SURVEY of the situation in the United States at the present time makes it increasingly certain that those industries there that are working on war contracts are receiving a very decided preference. In fact it amounts to this, if an industry is not working on essential work, the chances of it receiving sufficient supplies to keep in operation are very poor indeed. A review of the conditions existing at present in the pig iron centres of United States gives the following information:

Chicago—One deal that was sanctioned by the Government here this week makes it apparent that for the first time in some days manufacturers of railway equipment are going to receive some consideration at the hands of the Government. In the case referred to an allotment of 7,500 tons of basic iron was made to a leading independent steel maker to be worked up into railway equipment.

Boston—Manufacturers of stoves in this district are making a strenuous fight to see if they cannot have greater supplies released to them and some of them are using rather ingenious methods to secure these. For instance, the oil stove manufacturers are arguing that their products in causing the non-use of coal are serving a double purpose in conservation—crude and fuel. Indications are, however, that they will hardly get past with his claim, and they are not likely to receive any more iron than they have been doing in the past. In accordance with the desires of the Government, no iron is being sold for 1919 delivery.

New York—It would not be a very hard matter for any person to book a large amount of 1919 business here, but the Government has requested that this policy should not be followed and for that reason 1919 business is not being booked at the present time here.

Philadelphia—The intense humidity of the past few days has been considerably affecting furnace operations in this district. In a few cases, Eastern furnaces are booking occasional orders from regular customers for iron for first half of 1919 delivery, but these cases are very much the exception rather than the rule.

Pittsburgh—The trend of war trade and industry can be noticed here in a great many ways, one of them being the increasing number of consumers of pig iron that are shifting from non-essential to essential production. This has made it necessary to some extent to revise the lists already made out by the Government in connection with these industries. The War Board discourages the idea of uses of pig iron except in contracts without first having assurance that they will be able to obtain their raw material. Furnace operations are unusually heavy, but it seems unlikely that production will be large enough to meet all the essential demands.

Youngstown, Ohio—The situation in regard to pig iron in this district can very accurately be described as a serious one at the present moment. Producers of pig iron declare that they cannot see their way clear for months to come and are very much alarmed over conditions.

Buffalo—Any concern in this district that is producing any pig iron seems to be quite satisfied at the present time to allow the Government to take over the functions formerly discharged by its sales staff. They seem to be quite confident that Washington will be able to take care of the production of all their furnaces.

St. Louis—Inquiries here bring out the information that foundry iron for non-war usage is rapidly shrinking to very small dimensions. Shops that a month or six weeks ago were hoping to be able to continue operations are now taking a very pessimistic view. It is estimated that with what they have now on hand and what is on the road and by the generous introduction of scrap, a number of plants will be able to operate until the end of October, but it is almost certain that from that time on there will be a continued falling off of the operations.

HOT WEATHER BROUGHT SMALLER DECREASE THAN USUAL IN PRODUCTION

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Aug. 15.—A thorough canvass has been in progress as to the feasibility and desirability of increasing the output of steel by new construction. Not only the sanction, but also the hearty co-operation of the War Industries Board would be requisite before anything could be undertaken. A large amount of labor would be required, also a great deal of material, and much transportation would be involved and the matter would have to be considered from all angles. While the steel industry is fully able to finance its new construction itself, when it is new construction dictated by prospects of making money, the new construction that would be requisite at this time would not have such a future before it. After the war the industry would be left in an unbalanced condition. Indeed, it is only because the industry is quite out of a state of balance by reason of the peculiar nature of the war demand that it becomes feasible to increase the output of finished material by a relatively small volume of new construction. Study has shown that many of the finishing branches of the steel industry are quite insufficiently supplied with raw steel in the form of ingots, blooms and billets because such a large amount of raw steel is withdrawn from the situation by the demand for shell steel and the extra demand for plates. By the erection of a large number of open-hearth steel furnaces and a number of blast furnaces the production of finished steel would be greatly increased. The finishing capacity is already available, being indeed idle at present in considerable part, while there is also in prospect sufficient coke and sufficient Lake Superior iron ore to take care of many additional blast furnaces. If men, materials and transportation facilities were withdrawn from other activities to a sufficient extent the new capacity might be completed in the course of about six months, the question being whether it would be enterprising to make such withdrawals.

Plenty Lake Ore

Shipments of Lake Superior iron ore down the lakes in July totalled 10,659,203 gross tons, the record for any month in history, and bringing the season total to August 1 up to 29,608,933 tons, which presages a total movement for the season of about 65,000,000 tons. This is 10,000,000 tons above the inside estimate made before the opening of navigation. At that time the railroads had only partially recovered from the great blockade of the winter, and the entire matter of moving ore for the coming season hinged upon the railroads. All the plans provided that the convenience of the railroads should be served, the boats only moving so fast as the railroads could serve them. Since then the railroads have gotten into excellent shape and there is no difficulty at all about moving ore.

Heavy Freight Movement

As an evidence of the railroad situation, the latest statistics are for April and they show that even in that month the railroads moved freight at the rate of about 448,000,000,000 ton-miles a year. Prior to 1916 the best fiscal year total was 301,398,752,108 ton-miles, in the fiscal year ended June 30, 1913. The best posted shippers in Pittsburgh always contended, when the railroads were so badly blockaded last winter, that what they needed was system and locomotives. Government control has given them system and the locomotive shops have furnished many locomotives. Shippers did not feel that the railroads needed cars at all badly, for indeed one trouble was that the existing cars were blocking the tracks. Since April, which showed the freight movement just noted, there has been a further and great improvement in the railroad situation.

Steel for Jobbers

The pipe and wire mills find they can do fairly well in carrying out the War Industries Board's program as to shipments to jobbers during August, it being permissible to ship as much steel in August, as the monthly average shipped during the first half of the year In sheets and merchant bars it will be difficult to ship more than a fraction of the tonnage permitted. Some of the pipe mills had already received specifications from their jobbers during the first week in Auust. The American Steel & Wire Company issued a circular to its

Shrapnel First Used in Peninsular War

Shrapnel Originally Invented by Lieut. Henry Shrapnel—In Its Early Form Very Different From Present-day Shrapnel, and Was Used in Muzzle-loading Cannon

By J. N. ROBINSON

MECHANICAL appliances for throwing projectiles were produced early in the history of organized warfare, and "engines invented by cunning men to shoot arrows and great stones" are mentioned in the Old Testament. These were continually improved, and under the various names of catapulta, balista, onager, trebuchet, etc., were employed throughout ancient and medieval warfare.

The machines finally produced were very powerful, and even when a propelling agent as strong as gunpowder was discovered and applied, the supersession of the older weapons was not effected suddenly nor without considerable opposition.

The date of the first employment of cannon cannot be established with any certainty, but there is good evidence to show that the Germans used guns at the siege of Cividale in Italy in 1331.

The first guns were small and vase-shaped. Towards the end of the 14th century, however, they had become of huge dimensions, firing heavy stone shot of from 200 to 700 lb. weight. A gun of this latter type is still extant in the Bombarde de Ghent, called "Dulle Griete." It weighs about 13 tons, is 197 inches long and has a bore of 25 inches. It fired a granite ball weighing 700 lbs.

The first projectiles fired from cannon were the darts and stone shot which had been in use with the older weapons. These darts had iron heads or were made of iron, and were wrapped with leather to fit the bore of the small guns, and continued in use up to nearly the end of the 16th century.

Stone Much Cheaper

Spherical stone shot were chosen on account of their cheapness. Lead, bronze, and forged iron balls were tried, but their cost prevented their general adoption. Further, as the heavy metal shot necessitated the use of a correspondingly large propellng charge, too great a demand was made on the strength of the feeble guns of that period. Stone shot being about one-third the weight of those of metal, the powder charge was reduced in proportion, and this also effected a great economy.

Both iron and stone shot were occasionally covered with lead, probably to protect the bore of the gun. Cast iron, while known in the 14th century, was not sufficiently common to be much used in the manufactnre of shot, although some small ones were made about that time. They were used more frequently at the latter part of the following century. Towards the end of the 16th century nearly all shot were of iron, but some stone shot were still used in certain styles of guns for attacking weak targets such as ship at short range.

Various Kinds Were Used

In the 16th and 17th centuries various other kinds of projectiles besides the solid ball were used. Amongst these were the following:

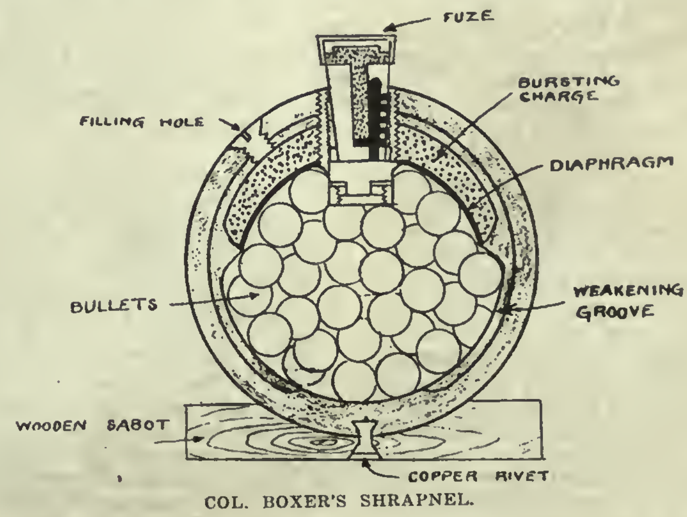
Case shot.—These are nearly as ancient as spherical shot and can be traced back to the early part of the fifteenth century. In the earlier forms lead or iron shot were packed in wood casks, in canvas bags or in cylinders of sheet iron. These shot were really the forerunners of our present shrapnel shell.

Grape shot.—This is now obsolete. It generally consisted of three tiers of cast iron balls, separated by iron plates and held in position by an iron bolt which passed through the center of the plates. Three was also another type called "quilted shot," which consisted of a large number of small shot in a canvas covering, tied up with rope.

Chain shot.—In the days of sailing ships these were in much favor as a means of destroying rigging. Two spherical shot were fastened together by a short length of chain. On leaving the gun they began gyrating around each other and made a formidable missile.

Red hot shot were invented about 1580 by the King of Poland. They were used with great success by the British during the siege of Gibraltar.

Marten's shell was a modified form of the latter. Here a cast iron shell was



COL. BOXER'S SHRAPNEL.

filled with molten iron and immediately fired. On striking the side of a ship the shell broke up freeing the molten metal, which set fire to the vessel.

The Steps of Progress

From the early history of ordnance we see great changes in size, shape and build of cannon and projectiles from the 14th to the 17th centuries. From then on until the middle of the 19th century, very little progress was made. About 1854 breech-loading rifled guns began to replace the old muzzle-loading smoothbores, and from then on until the present time we see enormous progress.

Explosive shell do not appear to have been in general use before the middle of the 16th century. About that time hollow balls of cast iron were fired from mortars. These balls were nearly filled with gunpowder and the remaining space with a slow burning composition. This plan was unsatisfactory as the composition was not always ignited by the flash from the discharge of the gun, and moreover the amount of composition to burn a stipulated time could not easily be gauged. The shell was therefore fitted with a hollow forged iron or copper plug filled with slow burning powder. It was impossible to ignite with certainty this primitive fuse simply by firing the gun. The fuse was consequently first ignited and the gun fired immediately afterwards. This entailed the use of a mortar or a very short gun, so that the fuse could be easily reached from the muzzle without unduly endangering the gunner. Cast iron spherical shell were in use up to 1871. For guns they were latterly fitted with a wooden disc called a sabot, attached by a copper rivet intended to keep the fuse central while loading.

The Work of Shrapnel

In 1784 Lieut. Henry Shrapnel, R.A., ((later Lieut.-Gen.), soldier and inventor, took up the study of hollow projectiles. He invented the forerunner of the present shrapnel shell. This shell was spherical in shape and was filled with lead bullets mixed with the bursting charge. A fuse arrangement, the same as that described for common shell was used.

In 1803 this shot case or shell was recommended for adoption into the service, and in the following year was first employed at the battle of Surinam. The results of its use in the Peninsular War were highly satisfactory to Wellington.

Although far superior to common shell in man-killing effect, their action was not altogether satisfactory, as the shell, on bursting, scattered bullets in all directions, and there was a liability to premature explosion.

In order to overcome these defects, Col. Boxer, R. A., separated the bullets from the bursting charge by a sheet iron diaphragm. The bullets were also hardened by the addition of antimony. Then, as the bursting charge was small the shell was weakened by four grooves made inside the shell and extending from the fuse hole to the opposite side.

The Shape was Changed

When breech-loading rifled guns supplanted the old smooth-bore muzzle-loaders, great changes were made in the shapes of the projectiles. Upon experimentation it was found that an elongated, sharp-nosed, shell would carry farther and more accurately than those of spherical shape, and these latter were gradually abandoned.

This new form was eventually used in the manufacture of shrapnel. But although its form was altered its character remained. The body of the shell was still made of cast iron, with a cavity at the base for the bursting charge, on this was placed a thick steel diaphragm, separating the bullets from the charge with a brass tube which communicated the flash from the nose fuse to the bursting charge. The body was filled with hard lead bullets and a wooden head covered with sheet iron or steel surmounted it and carried the fuse.

The new-shaped, elongated projectiles were at first fitted with gun-metal studs arranged around them in a spiral manner corresponding to the twist of the rifling of the gun. This was defective, for it allowed—as in the old smooth bores—the powder gas to escape through the clearance between the shell and the wall of bore (called the "windage") with a consequent loss of efficiency; it also quickly eroded the bore of the larger guns.

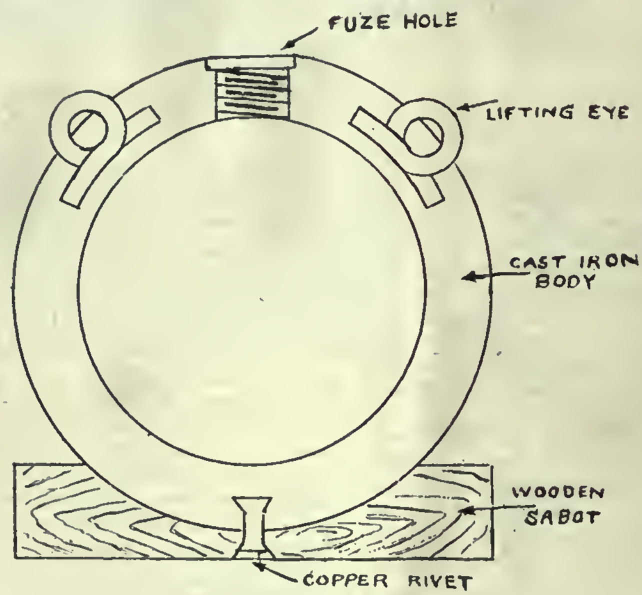
Many schemes were tried to give the shell rotation, and at the same time stop the leak of gases past the shell. In one case the bore of the gun was hexagonal in shape, with the shell to correspond. Another was elliptical. However, none of these produced the desired result.

Improvements Followed

Later the rotation was effected by a cupped copper disc called a "gas check" attached at the base end of the projectile. The powder gas pressure expanded the rim of the gas check into the rifling grooves and prevented the escape of the gas; it also firmly fixed the gas check to the projectile, thus causing the shell to rotate. A more regular and efficient action of the powder gas was thus ensured and a greater range and improvement in accuracy effected.

The late Lord Armstrong invented a shell coated with lead, which was forced into the rifling grooves of the gun by the pressure of the exploded powder gas. However, this lead coating proved too soft for the higher velocities of the modern guns.

Mr. Vavasseur, C.B., devised a plan of fitting, by hydraulic pressure, a copper "driving band" into a groove cut around the body of the projectile. This is now a universal practice with all kinds and sizes of shells. It not only fulfills the purpose of rotating the projectile, but renders possible the use of large charges of slow-burning explosive.



CAST IRON SPHERICAL SHELL.

Projectiles vs Armor

On the introduction of iron sheeted ships it was found that the ordinary cast iron projectile readily pierced the thin plating. Then, in order to protect the vital parts of the vessel wrought iron armor of considerable thickness was placed on the sides. It then became necessary to produce a projectile which would pierce this armor. This was accomplished by Sir W. Palliser, who invented a method of hardening the head of the pointed cast iron shell. These shells proved satisfactory against wrought iron armor but were not serviceable against compound and steel. Forged steel shell took the place of the Palliser shell. Carbon steel was first used, but as armor improved in quality projectiles followed suit, and the latest type of shell are formed of steel—either forged or cast—containing both nickel and chromium. Tungsten steel has also been used with success.

By making the body of toughened steel and by slightly reducing the size of the bullets, the number of these was much increased. Thus, with the cast iron body the percentage of useful weight, i.e., the proportion of the weight of the bullets to the total weight of the shell was from 26 to 28 per cent., while with the modern steel shell it is from 47 to 53 per cent. The limit of the forward effect of modern shrapnel at effective range is about 300 yards, and the extent of front covered is about 25 yards.

This is indeed a far cry from the first spherical shrapnel which were liable to burst anywhere from the time they left the muzzle of the gun to when they hit the ground, and threw bullets promiscuously in all directions—or did not burst at all—to the highly efficient modern shrapnel shell such as used by the famous French and American quick-firing "seventy-fives," and the British "eighteen pounders," which hurl shell with a rapidity almost unbelievable and with an accuracy which seems uncanny to the novice.

A USEFUL CU-FE-ZN HIGH TEMPERATURE BRONZE

By M. Mark.

It is fairly well known that pure iron and copper will alloy together in almost any proportion, and it is also fairly well known that aluminum will alloy with both iron and copper in the absence of carbon, and while it also acts as a flux for both metals, a boron derivative has better effect. It is also fairly well known that bronzes which hold iron resist corrosion well, provided the iron is alloyed with the copper and is not a mere mechanical mixture. Zinc and tin will alloy with both iron and copper, provided there is no carbon present in the iron but in the presence of carbon, or when the iron is unskimmed and covered with dirt, trouble arises in practical working.

Absolutely pure, carbon-free iron is, of course, not commercially obtainable, but very fair samples can be had in the form of Swedish bars of some brands, some forms of boiler plates, and some brands of mild steel, the amount of carbon held both in the combined and graphitic states being extremely low, and while this in itself is a disadvantage it does not prevent alloying with copper up to perhaps 30 per cent. iron to 70 per cent. copper, where care is taken, and indeed, with many practical tests alloys that would roll well and also draw into tubes were produced with a content up to 20 per cent. iron, but above this there appeared to be trouble.

In all cases the procedure was to melt the iron, add somewhere up to 25 per cent. carbon-free ferro-aluminum to the iron, and when reaction practically ceased, the dirt was skimmed, and the copper heated to redness, put in and melted, the zinc made as hot as possible, being finally added, and then after stirring and skimming the metal was poured into ordinary sand moulds or metal ingot moulds as the case may be, the metal moulds being thickly lime-washed and dried prior to the molten metal being poured into them. In these cases, Swedish iron of the best quality was used, and for this reason the aluminum was low, but with some broiler plate punchings and other scrap irons of less purity up to 0.30 per cent. of aluminum was necessary, this necessitating a much larger percentage of ferro-aluminum. In any case, the amount necessary to secure the best results would have to be determined in the laboratory; but a small excess of aluminum would not matter, although it would increase the cost of the alloy. In every instance the exact composition of the alloy must be determined by practical trial to secure the best results in regard to the articles for which it is used, this being a very essential point, because not only do the metals used vary in content, but different degrees of hardness and strength are desirable under varying circumstances.

As the melting point of wrought iron is high, probably in most cases forced draught will be necessary in the furnaces, which, for the sake of economy, should hold four 75-lb. crucibles of the upright or barrel type, but of course, single pot furnaces can be used. In any case, from 2750° F. to 2975° F. must be secured or the iron will not melt readily. and where a somewhat higher temperature can be managed all the better; but this implies about the maximum refractoriness in both furnace linings and crucibles. Usually it takes about two hours to melt iron in a good furnace, while in a bad one it may take much longer, or the iron may even refuse to melt.

The crucibles should be of clay—in which case they only stand one day's work—or of plumbago with clay liners, as made by the Morgan Crucible Company, to take one instance; in either case the cost for crucibles being much higher than for ordinary bronze; but even at this the cost of the Cu-Fe-Zn alloy works out at very much less than the ordinary Cu-Zn bronze, when all costs are taken on a pre-war basis.

It must be particularly insisted on that the absence of carbon is the crucial point, but conjointly with this silicon must also be absent or the iron or alloy will absorb carbon and soon become a mere mechanical mixture of metals of more or less—generally less—perfect combination, which are liable to dissociate at very small provocation. In the experimental work carried out by the writer, both in regard to this alloy and to "Mitia" iron castings, it appeared that while a small percentage of combined carbon was not seriously objectionable so far as untested apparent effect was concerned, the presence of even 0.25 per cent. of graphite carbon had a very prejudicial effect, and in cases where grey cast iron was used in part or whole substitution of the wrought iron, a very imperfect mechanical alloy was secured in which the iron floated, and this quite independently of the presence of either tin or zinc or both combined. The only way by which a good mechanical alloy of copper and cast iron was produced was by the addition of aluminum in sufficient quantity to (on paper) make the specific gravity of the Cu-Al combination equal to that of the iron. In each case the trials were of a practical commercial character, not less than 56 pounds of the alloy being made at each operation.

There are no patents in force for the making of the bronze alloy mentioned, "Mitza" malleable wrought iron, or artificial "Monel" metal, which is an alloy of nickel, copper and iron, and the only real difficulty in making these things is the high heat necessary and the absence of carbon in the metal. Good alloying skill is, of course, a necessity, but this, of all things, must be taken for granted as a general thing.

NITER CAKE FOR PICKLING BRASS

By Mark Meredith.

Niter cake, as a substitute for sulphuric acid in pickling brass, is finding extensive use in Great Britain. The quantity so used in that country now runs into several hundred tons per week. Difficulty in obtaining raw material, coupled with the increased demand for sulphuric acid for other purposes, has resulted in an extended application of niter cake solutions in place of dilute sulphuric acid for pickling annealed brass.

Niter cake is essentially crude acid sodium sulphate, and while the latter in the pure anhydrous state contains theoretically 40.8 per cent. of sulphuric acid, the free acid found in niter cake may vary from 3 to 30 per cent. For pickning, the niter cake solution should show 3 to 5 per cent. sulphuric acid on titration; there is no advantage to be gained in using solutions of higher acid concentration.

While niter cake is a variable product, annealed brass from a pickling point of view may be even more so. Given clean work, niter cake solutions replace dilute sulphuric acid quite efficiently, but with dirty work the difference is much more marked, and niter cake solutions, even under the most favorable conditions, may fail to pickle the work satisfactorily. It is little consolation for the manufacturer to know, that his troubles lie in his annealing furnaces. Much may be done to overcome troubles as follows:

The niter cake solution should be as hot as possible. Its acid content should be tested frequently and maintained at 3 to 5 per cent. by the addition of niter cake. The hot annealed products may be quenched in water, whereby much scale is mechanically loosened prior to pickling.

The hot annealed work may be placed direct into the niter-cake solution, and the pickle can thus be maintained at a high temperature without auxiliary steam heating.

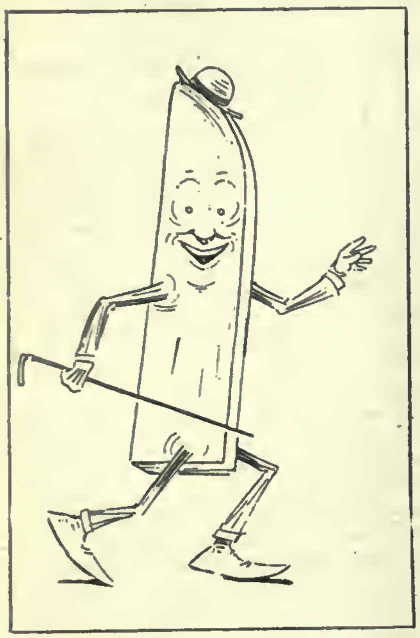
Electrochemical aid might be sought by using a low voltage current, making the lead lining of the vat the cathode and the work to be pickled the anode.

The difficulties met with in the successful use of niter cake solution can only be overcome in a satisfactory manner by paying close attention to the conditions governing the annealing so as to obtain the annealed brass as clean as possible, and by using the niter cake solution under conditions which will most strongly stimulate its pickling activity.

There's No Joy in Life for This H.S.S. Tool Bit

Things Used to Look Rosy When He Lay on Velvet in the Show Case, but the Life and Ginger Have Been Squeezed Out of Him Since Then—Real Sob Story by a Bit of Steel

By R. S. MYERS, BRIDGEPORT



WHEN H.S.S. WAS YOUNG AND KEEN

I AM a poor cripple. I have been twisted and contorted until I am nothing more than a mass of shapeless, sacrificed steel, with grains misplaced, sides twisted and out of line, grinds and cracks standing out here and there as a protest and protection against the friction of my square hole resting place, called a tool holder.

There was a time when I was fair to look upon. My skin was silvery and smooth like velvet. My sides were straight and shapely. My master was then proud of me. I enjoyed real freedom, the air and sunshine. Life then was a continual delight. But as I grew older my master became less thoughtful of me—he even left me in the tool holder locked up all night in the lathe tool post. I was not admired as much now. It was then that he began to criticize me—he discovered that I would not cut chilled iron and hardened steel. I soon realized that he considered me N. G., and my showings not up to the efficiency standards. He began by putting me into a fire that almost consumed me, and finished by dropping me in cold oil—I almost cracked on him on this occasion. I made him frown and grumble and scold for his ill-treatment.

My life thereafter was a steady torture. My master was hard for some time after he began ill-treating me, but I never knew a peaceful moment until I was turning C. R. S. or planing babbitt, when I would have a chance to work all day without being sharpened. But when the next day came I would again be thrust in my square hole chamber. At times I was almost split apart when a big monkey wrench forced the holding screw down on me. My close grain was forced so hard that the screw was actually expanded in the process.

I began to lose much of my feeling. I became hardened to suffering. I had to endure it. I was helpless.

Slowly and surely I lost my good shape, and my master's interest was less in a similar degree. I know on occasions he suffered lost time on account of his crimes against me.

Sometimes he would show me to some of the other boys and brag about how I cut such and such a steel at so many R. P. M., and at such times I would be hopeful. His sympathies for me and my hard knocks were at last awakening, but the next day I would again be similarly abused.

How I longed for my old home in the show case that greeted me in my younger days. My master then did not know about H.S.S.; true he could turn, mill, and shape, but when I came to him he was mighty proud of me and treasured me highly.

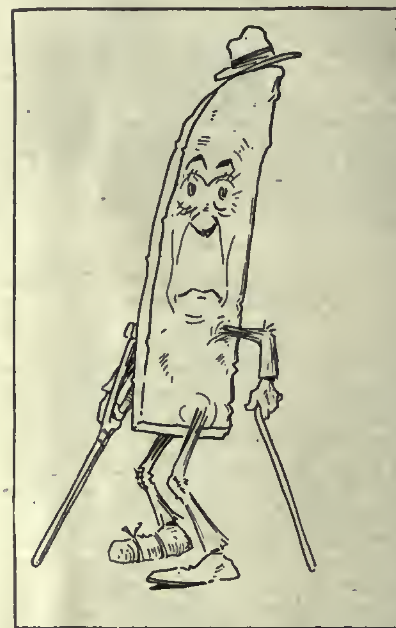
But when he began to crush the life out of me by welding me to a decrepit old piece of machine steel, he could not use such high speeds and feeds on his work. He finally lost his rep. for being the fastest workman in the room. His increased production was being replaced by minimum output. How I did abominate being welded to a simple piece of M. S. My master would attempt to force me to take a big bite, while I had all I could do to keep in my place—I broke my bonds twice, and was almost lost.

Now my master holds me on a M. S. shank in a more dependable way. His pride has borne many hard blows, but much of his trouble came because he maltreated me. He sold his record for the privilege of experimenting with me.

His reputation disappeared long ago. He has lost his energy, his enthusiasm. His record once on the production boards have been rubbed out. His interest has become indifferent.

And now my master blames me because I do not cut as at first. I chatter and squeak. He often complains, too, that the boss gives him no more "hurry up jobs." I tried hard enough to make him see that when ill-treating me he was injuring his reputation. He depended on me for a raise.

I gave him a proper foundation. Without my characteristics he could have never finished some of his jobs. Without my gifts he never would have held his job, and when he rehardened me—when



WHEN H.S.S. GREW OLD AND DECREPIT.

he melted me and chilled me beyond recognition, he paid the penalty in full. The joys of maximum production were his only so long as he gave me proper consideration.

Lack of head work made me a poor cripple. Hardened steel and chilled iron turned with the mistaken impression that I would "bite anything under the sun," robbed me of my greatest asset, and the price paid by my master for his folly was the loss of many dollars in his pay envelope years and years before they should have left him.

Many attempts have been made to weld the particles of tungsten together by working at a very high temperature. No headway has been made in this direction. To be workable, a piece of tungsten must be substantially nonporous—that is, the individual particles must have been previously welded together at a temperature near the melting point of tungsten in an atmosphere of hydrogen or other gas which is either helpful or at least not harmful to the tungsten. Sometimes the swaged tungsten rods split during the swaging operation. Attempts have been made to weld these split portions together by working at a high temperature. The highest temperature available was 1700-1800 deg. C. It was not found possible to weld the tungsten in this manner. Tungsten can be welded electrically at temperatures near fusion.

THE COMMERCIAL AWAKENING OF THE EAST

By Mark Meredith

JAPAN has thoroughly awakened to the possibilities of creating wealth and power by industry and commerce, and her neighbor China is awakening too, after a sort of sleep of many centuries for at one time she was, among the ancients, the foremost commercial nation. But the most interesting feature about the far East at present is the gradual development of a factory system, which is spreading, and travellers now talk about the factory towns of Japan and also of some parts of the industrial parts of China.

All the commercial centres are alive to the possibilities of development at the present time, for it is recognized that the greater the production of Japan in various articles and commodities which the Western Allies cannot give the time and attention to make the more she will keep the trade of the Allied nations going. The war has given the nations of the East many opportunities and as they are keen and enterprising business people they are taking full advantage of all that can be grasped. The Japanese were regarded as a coming force in the commerce of the world before the outbreak of the war but nowadays they seem to have "got there" for at various times many goods of Japanese origin have been on sale in towns all over Great Britain. There are many ways in which Japan is helping us in the shipbuilding, shipping and textile industries, and after the war she will certainly take her place as one of the great commercial nations of the East.

The position of Japan in the world freight market has witnessed a radical improvement since the war opened, but besides what has been achieved by the United States in this field of commercial activity, Japan's progress has been somewhat slow. The prosperity of the United States and Japan is due chiefly to Germany's submarine warfare, which has destroyed a large percentage of the world's merchant marine, and to the greater use of ships for war purposes by the belligerent powers. Great Britain has already lost nearly 45 per cent. of her merchant marine by the German submarine ravages and she has withdrawn many big merchantmen to carry troops and their requirements so that the greater part of her tramp fleet is not available for commercial purposes. Some regular liners have also been taken away from the trade routes where they had gained a firm footing through many years' steady work. From the far East, for instance, many well known liners have gone, and judging by the annual reports the directors of the different British lines, the results of wholesale withdrawal are viewed with anxiety for the places thus vacated are being filled rapidly by Japanese ships and the newcomers will gain a permanent footing.

It will be difficult for British lines to re-establish their influence and moreover, they will not have tonnage enough to do that. If Great Britain could afford to release shipbuilding yards from war service, the loss could be easily made good, but for the present nothing will be more difficult for that country to achieve. At least 600,000 tons of shipping are planned by her to be built, but it is too little to fill the gap. The United States, on the other hand, has been quite successful in enlarging her merchant marine, since the war opened. Although no accurate figure is available at present, it is beyond a doubt that her fleet has been more than doubled. Moreover, she is going to build a large number of steel and wooden ships for commercial use. In the far East the liners under the Stars and Stripes are still small in number, but on the Atlantic and in South American waters, their growing trade is striking.

Japan's gain since the war's opening is also striking. In the East she has, although not completely, succeeded in filling the gap created by Great Britain's withdrawal. On the Pacific also, most of the trade is hers. A most prominent instance of Japan's achievement is the Nippon Yusen Kaisha's inauguration of a Liverpool service. The regular trade on this particular route is now almost entirely carried on by the Nippon Yusen Kaisha, although in the Autumn of 1918 the Osaka Shosen Kaisha will start a service on this route. Japan has also increased her fleet immensely, in spite of the limited capacity of her yards, which is due to the precarious supply of steel.

In order to remedy this defect however, a law was passed at a recent special session of the Diet to encourage the iron industry. The main provisions of this measure are: (1) That iron and steel works with an output of not less than 35,000 metric tons per annum will have the right to expropriate the owners of property on which it is necessary to locate the works; and (2) that works turning out not less than 5,250 metric tons per annum will be exempt for eleven years from business and income taxes, and from all forms of prefectural local and municipal taxation, as well as being allowed to import free of duty the machinery &c., required for the works. The figure of 35,000 metric tons is based on the assumption that it is not economical to erect works with a furnace capacity of less than a 100 tons per working day for 350 days, while the figure of 5,250 tons is based on a production of 15 tons per day for the same period, this amount being fixed for the benefit of the smaller concerns. With great industrial activity existing in the country and the shipbuilding boom at its height, the passing of this new law has resulted in the launching of a number of new undertakings. Some of these schemes are financed and planned by important groups, which have been impressed by the large increase in the consumption of iron in Japan, especially during the last few months.

After the war, Great Britain will strive to regain her lost trade, and she will have to compete for that which has already been won by Japanese commercial enterprise. She is entitled to fair success in this struggle and as she has long occupied a position of importance in the shipping trade of the world, and as her seamen are excelled by those of no other nation, she will succeed in regaining her lost position in a great measure. The Germans will also strive to regain what they have lost, but it is by no means certain that they will succeed, for it will be difficult for them to rebuild their fleet. The United States will also have to strive hard if she is to retain what has been gained in the East during the war, for her weak point is the Seaman's Law and shortage in efficient seamen. If this weakness is remedied she can retain the fruit of the past endeavours. The outlook, however, for Japan itself in the after-war struggle for the retention of her shipping gains is not particularly hopeful as she has inflated her merchant fleet too much. It is questionable whether Japan can keep all her ships in full employ. Japanese seamen, however, have a strong point which will be important factor in the post-war competition. They can work at a lower rate than American or Britain seamen. The possibility of having to relinquish their war gains is perhaps the reason why the Japanese shipping companies are declining to receive further bounties from their government. They desire to be quite free and unfettered but the Japanese Government is determined to give the aid. Ignoring all application petitioning the government to stop further shipping bounties, the department of Communication ordered the Nippon Yusen Kaisha, the Toyo Kisen Kaisha and the Osaka Shosen Kaisha, Japan's largest shipping firms, to receive the bounty. Details of the amounts of the bounties and the names of the firms whichf have been ordered to receive it are:

European service:—This line should be maintained by the Nippon Yusen Kaisha semi-monthly with all ships, each of more than 5,500 tons and sailing at 14 knots, making 26 round trips a year, and for which the government is ready to subsidize 1,689,850 yen in 1918, and 1,569,672 yen in 1919.

Puget Sound service.—This line should e operated by the Osaka Shosen Kaisha bi-monthly with 6 ships, each of more than 5,500 tons, sailing more than 14 knots, making 26 round trips a year, and for which the government is willing to give 2,669,925 yen in 1918 and 2,309,187 yen in 1919.

San Francisco service.—This is to be maintained by the Toyo Kisen Kaisha four-weekly with 3 steamers each of 12,500 tons, and sailing more than 18 knots, making 14 round trips a year. Owing to the fact that this line competes with more than one other foreign line, the government has refrained from announcing the exact amount of subsidy.

Pacific South American service.—The line must be operated by the Toyo Kisen Kaisha bi-monthly with 3 ships, each of more than 6,000 tons, sailing faster than 13 knots, making 6 round trips, and for which the government will give annual subsidy of 284,836 yen in 1918 and 269,350 yen in 1919.

Australian service.—This line is to be operated by the Nippon Yusen Kaisha monthly with 3 ships, each of more than 5,000 tons, sailing faster than 15 knots, making 12 round trips a year, and for which the government will give 169,470 yen in 1918, and 188,497 yen in 1919.

Turning to the industrial development in Japan the installation of plant of all kinds is continually increasing for both machine-making and manufacturing. War conditions in Europe have given the Japanese business men a fine opportunity in metallurgical and shipbuildinng trades. The total number of mills now manufacturing machinery is 1,180—that is mills employing men of 18 years and over—and these probably do not include textile factories mostly staffed by young females. Machinery shops are now prosperous, and they include makers of spinning and weaving plants. There are 1,951 dyeing and weaving establishments in Osaka district, an increase of 288 over 1916, many of them being small concerns, probably employing only a few hands. Nevertheless, the number of workmen in May, 1917, was 78,827 an increase of 3,830 over May 1916. All other kinds of industry show an increase in mills and work people, which seems to indicate that Japan is performing a share of the war work, including munitions. The cotton mills appear to have had a good year. The balance sheets of two spinning companies have been recently published—the Toyo and Amagasaki companies; the former declared a dividend of 40 per cent. in addition to which both concerns placed large sums to reserve and carried forward an important proportion of the total profits. Accounts of industrial activity and advancement all round indicates that Japan is forging ahead in manufacture while Europe is fighting

Chemical Industry

Another remarkable feature of the economic development of Japan is her extraordinary progress in the chemical industry. At the commencement of the war this industry was still in its fancy, yet to-day Japan exports chemical products for the supply of which she was but three years ago entirely dependent upon outside sources. Whether when the war is over Japan will have secured the foundation of this new industry sufficiently well to maintain it, is another matter. Without an adequately protective tariff it is doubtful whether she will, for, in spite of the availability of some of the raw materials in Japan itself or in the countries near at hand, in spite of the great advantages she posses in cheap labor, and the access she enjoys to cheap motive force by reason of her abundance of waterfalls, the chemical industry of Europe and the United States has gained such a footing in all parts of the world, that a new competitor is bound to have a very hard fight for existence when times are normal again. Nevertheless, the power of her industriousness and her genius, will secure her a place among the chemical producing nations, but it may take time as the chemical industry in Japan is an emergency one. Unable to obtain adequate supplies of chemicals from the ordinary sources of peace time, she has produced her own, and in some cases produced sufficient for export purposes. Great Britain can regard without envy the advent of Japan as a new competitor, but Germany will be the largest loser through the development of the Japanese dyestuffs industry. For many years to come Japan is bound to be a large customer of Great Britain for soda ash and caustic soda; in fact as she develops her other industries her need for these alkalies will become greater and, lacking what we possess, abundant supplies of cheap salt, it is at least doubtful whether Japan will be able in the near future to produce sufficient alkali to satisfy her home requirements. The production of soda was started in Tokyo, Osaka, and Yamaguchi Prefectures some thirty years ago, but, owing to the comparatively high cost of salt development has been slow. At the present time soda is being produced by an old system by the Canto Sanso Kaisha, of Tokyo Prefecture, and the Onoda Works, of Yamaguchi Prefecture. Accordinng to Dr. Toyokichi Tamatsu, one of Japan's distinguished industrial chemists, means have been studied for supplying industrial salt at a low cost, and, in addition, for working the ammonia and electro systems of soda making. Those engaged in Japan's progressive soap and glass industries—to mention only two of the commercial uses of alkali—would hardly consent without protest to a heavy protective duty on soda ash and caustic soda.

Turning to another branch of chemical industry, Japan has made wonderful progress in the production of Phosphorous; before the war Japan imported all the phosphorus she required for her match industry from England, France, and Germany. But now The Chemical Industry Company and the Fuji Electro-Chemical Company are manufacturing phosphorus from phosphite imported from the southern Pacific Islands, and some idea of the size of the output can be obtained from her huge export trade in matches. During 1915-16 she exported 14¼ million gross of matches, to India alone—this in spite of an Indian custom duty of 7½ per cent. Whether when English phosphorus again becomes available for export and prices become normal Japanese phosphorus will be the cheapest product for the match-makers to us remains to be seen. But, judging from the price at which Japan has been able to sell to India matches made from Japanese phosphorus, it would seem that the cost of its production from phosphorite is relatively low. Another match making chemical, potassium chloride, is being produced on an extensive scale in Japan at Aidzu, where the water power of Lake Inaswashire is utilized, and at various other places. It is also estimated that 10,000 tons can be made annually from seaweeds gathered on the coasts of Hokkaido, Karafuto, Chiba, and Kanagawa districts.

Japan is also making sulphate of ammonia from bye-products of the gas and coke factories and from nitrogenous lime The production of acetate of lime by the Japan Acetate Acid Company has also increased, and it seems probable that America will lose a good customer for the acetate. The Tokyo Gas Company is making carbolic acid, and the Japanese Dyestuffs Company has laid plans for manufacturing it from benzole. The yearly production of sulphuric acid in Japan is little short of three quarters of a million tons, and it is intended to establish a plant for the production of this acid by the contact process.

As to the dyestuffs industry, it is common knowledge that the Japan Dyestuffs Manufacturing Company has been founded and is backed by the government. Before the war Japan imported from Germany coal-tar colors to the value of something approaching a million pounds sterling, and, although the Japanese industry is still in its infancy, it is quite clear that Japan does not intend to go on paying such a tribute to Germany.

And in the Departments of Commerce and industry Japan is making rapid progress and there is little doubt that now her business men have awakened to the possibilities of trade and commerce her industries of all kinds will grow to a very great extent. There is no doubt Japan will make herself quite independent of Germany and German manufactures, and perhaps all the other Allied nations will follow her example.

Incorporation has been granted to the Campbell, Howard Machine Co. Ltd. The incorporators being residents of Montreal. The purposes of the company are as follows: To carry on the business of manufacturers of iron and woodworking tools and machinery, iron founders, steel makers, brass founders, metal workers, millwrights, machinists, etc. The capital stock of the company is placed at $650,000 and the head office will be at Sherbrooke, Que.

Heating and Ventilation Are Very Important

When a Factory is Being Constructed All These Details Should be Attended to—It is Sometimes Possible to Make Changes in Plans to Secure the Best Results

THE SECOND OF A SERIES BY M. H. POTTER.

THERE are many systems of heating buildings, among which are: By means of exhaust or live steam in lines of pipe arranged overhead or along the walls, by coils or radiators, by hot water utilized in a similar way; by air furnaces, or by contact with pipes through steam flows. All these systems have their good and bad features, both as to their warming qualities and their cost, as well as the expense of operating them. The hundreds of feet of steam pipes, with their numerous fittings, furnish at each joint opportunities for leaks, and special arrangements must be made to keep them clear of water. The distance from the boiler to the further end of long systems frequently requires much time to force the steam through to these points to warm the rooms so that they will be endurable to workmen.

The hot water system works slowly and the temperature of the surrounding air rises gradually, so that the hour for beginning work in the morning must be anticipated by such a length of time as to be a serious drawback to complete success. The hot-air furnace gives air from which much of the moisture is evaporated and which is therefore unwholesome, aside from the fine dust so often brought along with it. In all these systems heating is the only end gained, ventilation being left largely to chance.

The ideal system of warming and ventilation would seem to be that in which fresh air, warmed by steam heat, is distributed by a suitable mechanical progress, as evenly as possible to every part of the building, and one in which this can be done in the shortest time (as in most shops heat is not maintained during the night except at sufficient temperature to prevent freezing of water pipes, etc.), and in which cold air may be readily introduced whenever needed.

This seems to be best accomplished by drawing fresh air from without the building, passing it through a heating apparatus consisting of an iron case containing a large number of steam pipes, and by means of a fan and suitable pipes, distributing this warmed air to every part of the building by numerous outlets. The whole should be controlled by proper dampers, by which a due proportion of warm and cold air may be furnished as needed, so that proper ventilation as well as warming may always be maintained.

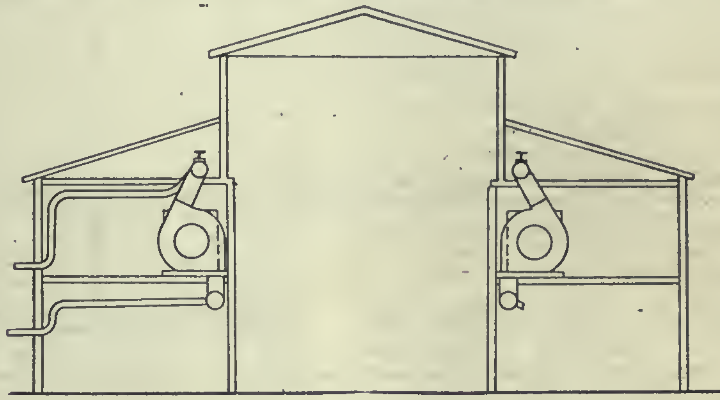


FIG. 4—CROSS SECTION OF FOUNDRY HEATING SYSTEM.

In the warming of such large buildings as those under consideration it is not necessary to draw cold air from the outside atmosphere to any great extent. The number of cubic feet of air contained in the building is largely in excess of that required for each person, and, cold air comes in through frequently opening large doors, while the swinging windows at the roof may be opened when necessary to permit the vitiated air to pass out, thus providing ample ventilation.

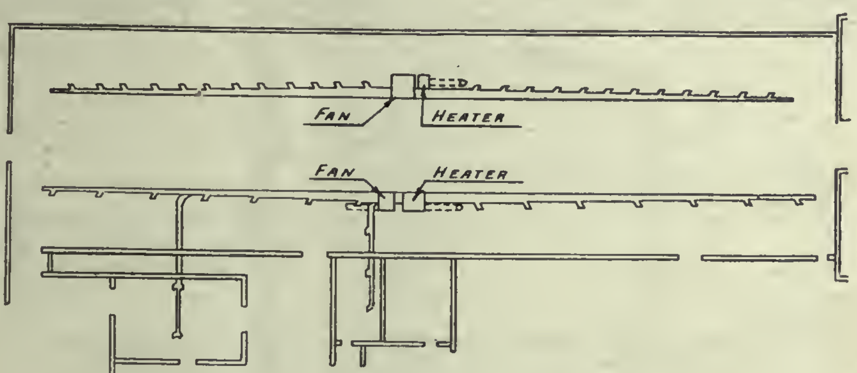

FIG. 3—PLAN LAYOUT OF FOUNDRY HEATING SYSTEM.

The heating apparatus should be located near the center of the building so as to distribute the warm air to all points with the least amount of piping. Openings should be so arranged as to be not over 30 feet apart, and to open toward the outer walls of the building. They should not be less than 8 feet above the floor, nor less than 5 inches diameter, and usually incline downward at an angle of about 10 degrees. The aggregate area of openings should exceed the area of the main pipe at the fan by about 25 per cent.

About 6 square inches area of openings should be allowed to every thousand cubic feet of space contained in the building or room, where the building is so divided. The velocity of air should not be less than 1,500 feet per minute, and a sufficient quantity should be supplied to change the air about every 25 minutes.

The pipes are preferably circular, as less material is required to make them of this form, circular pipes are stronger, and there is less friction of air in passing through them. However, square or rectangular pipes are sometimes necessary on account of lack of space. When such is the case this area of cross-section must be increased accordingly so as to overcome undue friction. Galvanized iron is the most desirable material for these pipes and is almost universally used where pipes separate from the building construction are used. In factory buildings having several floors, proper flues and air ducts are arranged in the walls, and in the basement, where the heating apparatus is usually located.

Machine Shop Arrangement

Fig. 1 shows the plan of arrangement of the heating system of the machine shop and Fig. 2 a cross-section of the same.

The heating apparatus consists of a rectangular iron case containing a large number of steam pipes of practically U-shaped form, inverted and connected to a cast iron base in such a manner that one leg of the pipe connects with the space through which the steam is admitted and the other leg connects with the space from which the drip is taken. These pipes should be located as close to each other as practicable, the rows of pipes being set staggering so as to break up the currents of air. The casing which surrounds them and connects with the inlet of the fan should also be formed as closely to the pipes as may be, in order that all air which is drawn through may come into close contact with the heating surfaces of the pipes.

It is customary to allow one foot of 1-inch pipe, or its equivalent, to each 100 to 150 cubic feet of contents of the building to be heated, when all the air is taken from out-of-doors. In the case under consideration, with one-half or more of the air from within the building the higher figure would probably be ample. At the end opposite the fan are located dampers for regulating the amount of air supply. One of these may be connected with a cold air duct from out-of-doors where necessary.

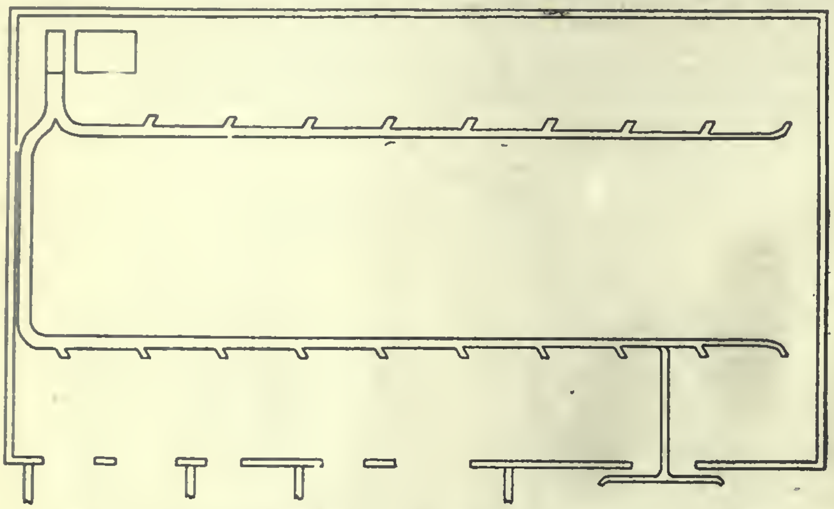

FIG. 1—PLAN ARRANGEMENT OF MACHINE SHOP HEATING SYSTEM.

Referring to Figs. 1 and 2 the location of the apparatus is seen to be in the gallery floor, near the centre of the building. The fan has two discharge openings, one downward for warming the side wings of the first floor, and one at an upward angle for the same service on the gallery floor. The returning currents of air flow into the central portion of the building and warm that portion in their upward course.

Two sets of apparatus are used, for the reason that the traveling crane over the centre portion of the shop prevents convenient connections between the two sides; and further, that the space to be heated is so large that the questions of convenience and economy are best met by this arrangement.

The apparatus on the side nearest the power house will require a fan with a wheel say 100 inches diameter by 52 inches wide, and running at about 185 revolutions per minute. This will supply from its downward opening the pipes for the main floor, including that leading to the carpenter shop and to the wash room on the first floor, and from its upward opening it supplies the pipes from the gallery floor, including one for the wash room on the second floor.

The apparatus on the opposite side of the shop should have a fan with a wheel say 90 inches diameter by 48 inches wide, running at about 250 revolutions per minute. The pipe connections are similar to the first apparatus, except that there are no long branch pipes to be provided for. Hence, while a 36-inch pipe is necessary for the side toward the power house, in order to warm the carpenter shop and the wash rooms, one of 29 inches diameter will be quite sufficient for the opposite side. It should be said that the dimensions given on the drawings are from actual calculations, taking into consideration all the circumstances of the form and dimensions of the buildings, and they will probably be found correct in practice as well as theory.

The openings for the discharge of warm air into the building are directed toward the outer walls and downward at an inclination of about 10 degrees. This arrangement is clearly showing in the drawings Figs. 1 and 2.

The pipes should be well riveted as they are put up, and securely fastened so that they may not be loosened by any jarring or vibration, either of the buildings or that caused by the pressure of air passing through them.

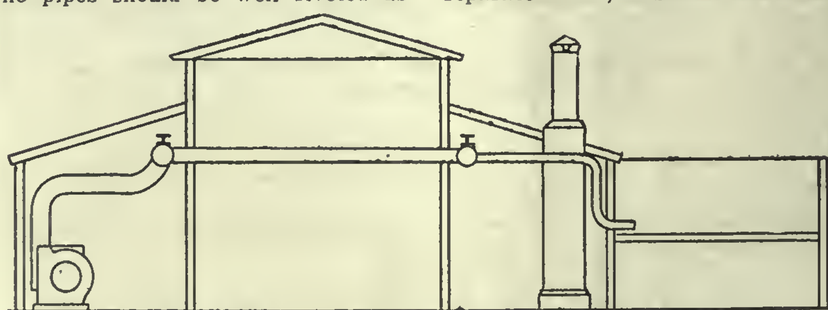

FIG. 2—CROSS SECTION OF PIPING ARRANGEMENT FOR MACHINE SHOP.

The fans may be driven by an electric motor or by an engine attached to each fan, or by belts from the main line of shafting.

Live steam should be used for heating. The large apparatus will probably require a supply pipe of 6 inches in diameter and the smaller one of 5 inches. The apparatus should be so constructed that a section of it may be separately connected for using the exhaust steam from the fan engine. In the same way the exhaust from the main engines of the works may be utilized and thus save a considerable portion of the live steam required.

Heating Layout for Foundry

In arranging for heating the foundry, different conditions are met with. With the exception of the chipping and pickling room heat is required hardly more than half the time, that is, during the forenoon, and perhaps for an hour or more after the dinner hour, as the heat from the cupolas is considerable. The general plan of the system is the same as that employed in the machine shop. The apparatus requires but little room on the floor and consists of a fan having a wheel about 78 inches in diameter and 24 inches wide, running at about 400 revolutions per minute, and will require about six horse-power to drive it.

An arrangement of pipes can be made whereby the chipping and pickling room could be warmed independently of the foundry proper, but it would probably not be necessary.

Figs. 3 and 4 show the arrangement of the foundry system of heating, with diameters of the pipes and openings. It will be preferable to run this fan by an electric motor, and since these fan blowers for heating purposes are now made with simple and compact engines attached to them, which require very little attention, aside from starting, stopping, and oiling, they are very convenient in such situations.

It is always important to have the heater as near the space to be warmed as possible.

System for Other Units

The office building, including the pattern shop, drawing room, and tool department, is heated by an apparatus located in the tool room and forming a separate system. It may be driven by a separate motor, or belted from the shaft which drives the machines in the tool room. The latter plan is probably the best, since the power is convenient, and the first cost may be lessened without sacrificing any desirable feature in another direction.

The main pipe passing through over the driveway must be amply protected, the space being filled with sawdust or similar material, and this again is covered by another box large enough to leave an air space of about three inches between the two, on all sides.

For the office rooms the pipes may be of rectangular form, concealed by suitable architectural finish of the ceiling, in which lateral openings for registers may be made. Or, proper air ducts may be formed in the side walls and the registers placed at suitable intervals. Or the pipes may be carried around inside the walls, close to the ceilings, and registers located in the same manner.

There may be for this system the double-duct arrangement. That is, two sets of pipes or ducts, one carrying cold and one warm air, the registers being so arranged that they will furnish one

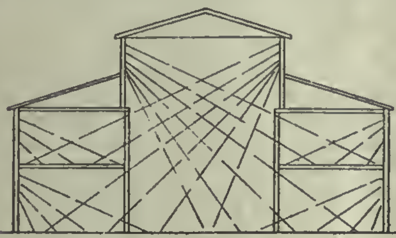

FIG. 5—CROSS SECTION SHOWING LIGHTING ARRANGEMENT.

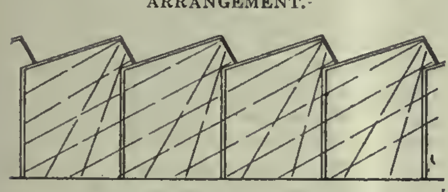

FIG. 6—CROSS SECTION OF SAW-TOOTH LIGHTING SYSTEM.

or the other, or a mixture of both, by means of what is technically known as a "mixing damper."

In offices and rooms of moderate size which are heated by warm air being forced into them near the ceiling, it is usual to provide means of escape for the air as it cools and descends to the floor, through grated openings placed two or three feet from the floor, and connected with flues or ducts leading to the roof. But in offices where doors are frequently opened this does not seem to be necessary, the problem of ventilation being of small consequence compared to that of heating.

The forge shop and various other buildings require no special arrangements of heating.

Suitable Temperatures

The question of proper temperature of shops where men are at active work should be considered as quite different from providing for heating a factory where the work is usually much lighter, the number of employees per hundred feet of floor space much greater, and frequently a large proportion of them females.

In a machine shop devoted to a medium class of work, a temperature of about 60 degrees will be found comfortable. The temperature in the storeroom, tool room and pattern shop will need to be about 65 degrees, and the drawing room and offices, between this and 70 degrees. Unless the ventilation is very carefully attended to, there is more danger in having these latter rooms too warm than not warm enough, and any system of heating which does not recognize the importance of good and thorough ventilation is radically wrong in both theory and practice.

Natural Lighting

For properly lighting a shop during the daytime, many forms and portions of windows have been devised, from those of small area and diminutive lights of glass, to those very high and narrow, those broad and low; those of large area placed far apart; those of much less area placed near together; those covering almost the entire wall with glass area; those placed vertical and those in an inclined position; those placed as skylights in the roof; and those placed in the ventilating space at the top or ridge of the roof.

Again, as to the kind and quality of glass used. Some prefer the ordinary plain glass, admitting a flood of light, regulating it by means of shades or curtains. Others use the same glass, stippling the surface with white zinc thinned with spirits of turpentine to relieve the eyes of the glaring light. Rough glass and ground glass is often used.

What is called ribbed glass with the ribs running in a horizontal direction, is probably better than either. In viewing these various methods of construction it may be said that broad and low windows in the side walls will light the bench at the wall and perhaps two rows of machines, where the centre of the room receives little or no illumination. This condition is sometimes sought to be remedied by the use of skylights in the roof.

Windows placed too high in the side walls will light the centre of the room but leave the benches around the walls in the shadows of the high window sills. Therefore it is proper to so locate the window sills as to afford proper light at the bench vises; then to continue the window well up to the ceiling in order that the whole room may receive, as nearly as may be, an equal quality of light.

Fig. 5 shows a cross-section through the machine shop, and gives the floor surfaces illuminated by parallel beams of light at various angles. It should be understood that in all these cases light is not confined to these surfaces, since it is always more or less strongly diffused over a much larger space. These diagrams are only intended to show the relative amount of illumination.

Fig. 6 is a cross-section of the newer form of saw-tooth roof construction. All illustrates the largely increased amount of surface lighted up by this method, which is now generally regarded as the best practice for lighting large areas in one-storey shops.

The width of the windows and the distance apart is a matter of great difference of opinion.

Artificial Lighting

Let us now consider the question of artificial light. To properly provide for sufficient lighting, we must select some one of the many systems in use, and the one which seems best adapted to the conditions of the case. To provide an ample, proper, safe, and thorough system of illumination for buildings in which a large number of persons are obliged to labor for so many hours each year by its aid would seem to be a matter that need not be argued or advocated. Yet there are many shops at the present time so constructed that some kind of an artificial light is needed all through the day, and in some nearly all seasons of the year, and this condition prevails over a considerable part of the working period.

In the application of electric light in manufacturing operations we have the choice of the arc lamp and the incandescent lamp. Both have their objections as well as their merits. The arc lamp, being much more powerful and projecting its rays a much greater distance than the incandescent lamp, is well adapted to illuminating large areas, where there are comparatively few objections. In confined situations, or where there are many obstructions, it produces disagreeable shadows, and its glaring brilliancy is hurtful to the eyesight of the workmen.

Translucent globes or shades may be used, of course, but these devices necessarily reduce the illuminating power of the lamp.

The incandescent lamp gives a much softer and more agreeable light to the eyes of the workmen, who may work many hours by its aid with less discomfort than by almost any other light. It is also much more portable than the arc lamp, since it may be provided with flexible conducting cords of any convenient length, and hung up or held in the hand in the most desirable position.

In the machine shop the clear space needed for the travelling crane precludes the suspending of arc lamps through this central portion, but they may be placed between and a little inside of the line of the columns. From the character of the machines employed and the work done in the galleries the incandescent lamp will be the most suitable. There should be at least one to each machine and in the case of long lathes one to every ten or twelve feet of bed.

The large open space of the foundry may well be provided with arc lamps.

The core room, wash rooms, offices, etc., will require incandescent lamps. The forge shops will be best served by two arc lights in the main part, and by incandescent lamps in the foreman's office.

The entire front building, including the offices, tool rooms, pattern shop, pattern storage loft, drawing room etc., should be lighted by incandescent lamps, those in each room being arranged to suit the peculiar conditions in each case, as to the kind of shades and reflectors employed.

AERO-PROPELLER SHAPING MACHINE

Aeroplane propellers, as is well known, are usually built up of laminations of wood of equal thickness glued and dowelled together. The built-up body is subsequently worked to the required shape very frequently by a purely hand-tool process. This method of finishing the body naturally calls for the exercise of highly skilled workmanship and is essentially slow. While the aero-propeller is geometrically a very complicated body, it is not impossible to reproduce its form by mechanical means with the requisite degree of accuracy. Much attention has been devoted to this matter, and as a result there are now obtainable, or in use, several forms of propeller-shaping machines.

PROPELLER SHAPING MACHINE. FRONT VIEW.

One of the most recent British designs of such a machine is illustrated in the accompanying engravings, for which we are indebted to the "Engineer." This appliance is manufactured by A. Ransome & Co., Limited, of Newark-on-Trent, who have brought it out in conjunction with Mr. J. J. Kerr, of Lincoln. The design is patented. Like all other machines of its class, it works by copying the profile of a model blade. So far as we know no machine has been designed to generate the form of an aero-propeller, the reason being probably the difficulty of dealing with the varying convex curvature of the forward face.

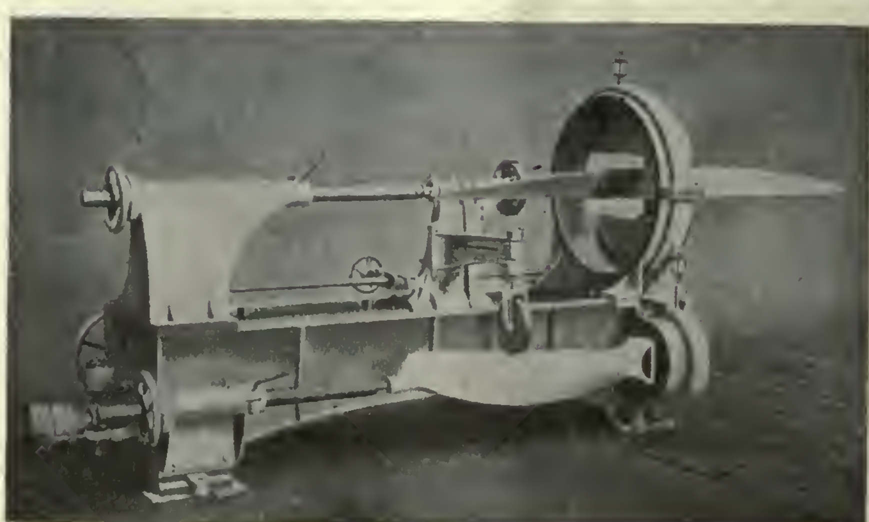
In the Ransome-Kerr machine the model propeller blade and the work are rotated at the same rate on parallel axes, the angular position of the model on its axis being 90 deg. in advance of that of the work. A travelling carriage provided with a rotating circular cutter head is fed slowly along a screwed shaft fixed within the frame of the machine. A copying roller bears against the surface of the model and swings the carriage about the screwed shaft as axis. An angle of 90 deg. being included between the lines joining the centre of the screwed shaft with the centres of the cutter and roller, the profile of the model is thus reproduced facsimile on the work as the carriage is fed along the screwed shaft.

The propeller being worked to shape is held by a bolt passing through its boss and two flanges formed on a circular cast iron driving head rotating within a casing which is bolted to the machine bed. The tip of the blade actually being operated upon is supported on a back centre at the end of the tailstock spindle. This spindle is of considerable length, to enable propellers of various diameters to be accommodated. The model blade is similarly supported between a driving head and a tailstock fixed to the side of the machine frame. The two driving heads are driven at equal rates through cut gearing from a belt-driven countershaft lying within the bed of the machine directly below the screwed shaft for the cutter carriage.

The cutter carriage is formed with a long bearing to receive the fixed screwed shaft. At its upper end it has two split bearings for the cutter spindle. Between these bearings the spindle carries a pulley from which a driving belt passes down to a sliding pulley on the countershaft. As the carriage pivots about the screwed shaft and not about the countershaft, this method of driving the cutter spindle might cause the countershaft to show a tendency to bind in its bearings. These bearings, however, as clearly shown in one of the views, are mounted so as to be able to turn about two axes and thus to accommodate any deflection of the countershaft produced by the pull of the cutter spindle belt. Feed motion is communicated to the cutter carriage from a split nut which, at will, can be engaged with the fixed screwed shaft. This split nut is rotated by gearing from the cutter spindle, so that should the cutter cease to revolve, as by the belt slipping off the sliding pulley on the countershaft, the feed motion will also stop simultaneously, and the work will not be damaged. In the transmission between the cutter spindle and the split nut a clutch is placed. This clutch is used to start and stop the feed, and is automatically operated to stop the feed when the cutter reaches the propeller hub. The cam operating the clutch handle for the latter purpose is carried adjustably on a bar running between the head and tailstocks. This bar also serves as an abutment against which a block, sliding in a link pivoted to the carriage, can be screwed so as to hold the cutter away from the work while the carriage is being traversed back to its starting point. The return movement of the carriage is effected by means of a hand wheel at the tailstock end of the bed.

Provision is made whereby the work may be brought to its finished size by a series of traverses or whereby the work may be turned out larger by multiples of half a milimetre than the model. Normally, the distances between the centre of the screwed shaft and the centres of the cutter and the copying roller are equal. The copying roller is, however, carried at the end of a screwed spindle having a handle fitted with a spring plunger which engages with the holes of a quadrant on the body of the carriage. By these means the length of the copying roller arm can be adjusted to give the cut required.

The machine can deal as readily with four-bladed as with two-bladed propellers, the two additional blades in the former case simply swinging clear of the driving head. The finish of the work turned out, and in particular of the knife edges of the blades is, we are informed, in every way satisfactory, the surfaces subsequently requiring only to be touched up with sand paper.



PROPELLER SHAPING MACHINE. REAR VIEW, SHOWING FORM.

Theory and Application of Sectional Views

Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simple Type—Practical Course Prepared For Younger Men and Newcomers in Industry

Fifth of Series of Articles By TERRELL CROFT

SEEK contrasts because contrasts render a drawing more pleasing to the eye and also make it more easily understood. Where bold lines are required for outlines, make them sufficiently bold so that they will be conspicuous by virtue of contrast, and so that they will indicate the contour of the object without minute examination. On the other hand, when fine lines, that is, light lines, are required, make them fine so that there can be no possibility of mistaking their intent.

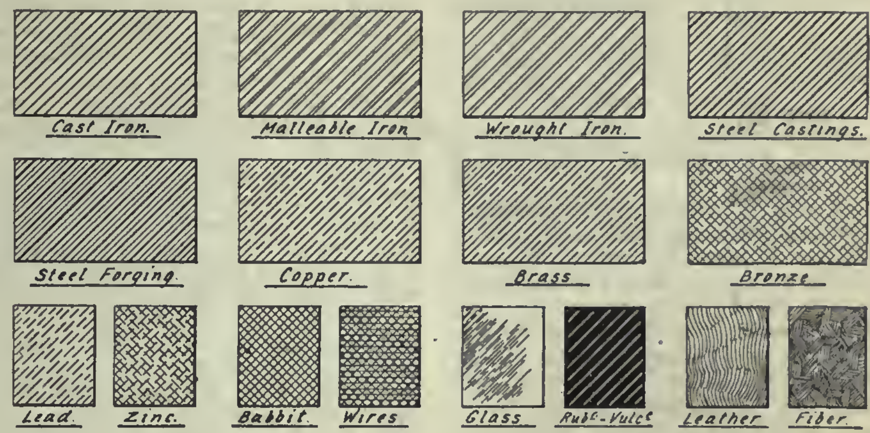


FIG. 5—SECTIONAL LINES TO DISTINGUISH DIFFERENT MATERIALS.

The reason that sectional views are used is that it often transpires that it is inconvenient, difficult, or even impossible to show the interior construction of an object by dotted lines drawn in on the exterior views. Furthermore, as has previously been suggested, it is often possible to show with one sectional view the detailed construction of an object which would, if plan, side, and front views were used for its delineation, involve the preparation of a complicated and expensive drawing. Just how these sectional views may be utilized will become apparent to the reader as he proceeds.

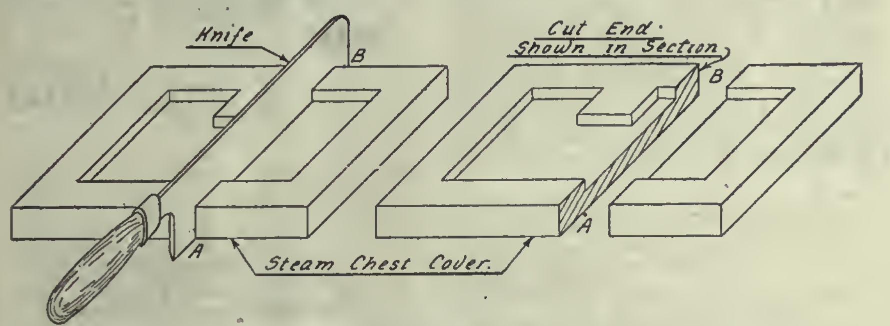

FIG. 1—CUTTING A SECTION FROM STEAM CHEST COVER
FIG. 2—PERSPECTIVE VIEW OF ABOVE AFTER CUTTING.

A sectional view of an object is drawn as if a portion of it were cut away. To understand thoroughly the meaning of the preceding sentence, let us make a sectional view of the steam chest cover which has been the subject of discussion in the foregoing articles. Assume that the steam chest cover is cut across with an imaginary knife as shown in Fig. 1. Then, if the two component parts were separated they would appear as delineated in the perspective view of Fig. 2. Looking at the end surface AB we would see the cut end or a sectional view through the casting. When plotted into an orthographic working drawing, the sectional view would then obviously be as shown at "Section AB" in Fig. 3. In actual practice, instead of thinking of the object as being cut through with a knife, it is usually more convenient to assume that it is cut by a plane, as diagrammed in Fig. 4. Such a plane may be called a "cutting plane."

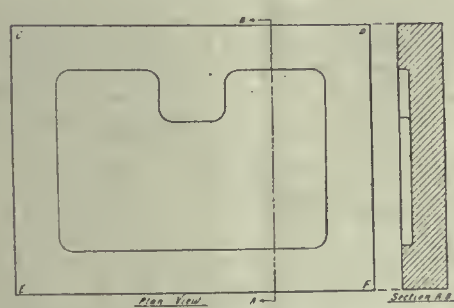

FIG. 3—WORKING DRAWING (WITHOUT DIMENSIONS) SHOWING SECTIONAL VIEW.

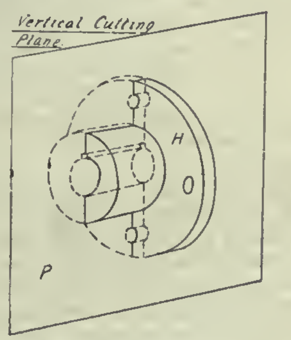

FIG. 4—SHOWING CUTTING PLANE FOR HALF SECTION.

It is always desirable to indicate the location of the cutting plane. For example, the cutting plane in Fig. 3 is located at AB, hence the words "Section AB," under the sectional view, indicate that this view shows the appearance looking at the end of the object when it is cut through on the plane AB. Note that a cutting plane or section line (for example AB in Fig. 3) consists of a series of dashes with two dots between each pair of adjacent dashes. A line thus made, with two dots and a dash, should be reserved to indicate only cutting planes and should be used for no other purpose. Sometimes the letters and the line indicating the location of the cutting plane are omitted from the drawing. Where this condition is encountered it may ordinarily be assumed that the cutting plane passes through the center—either the longitudinal center line or the vertical center line—of the object.

The exposed cut surface in a sectional view is cross-hatched; that is, section lines are used to indicate that the surface on which they are drawn represents a cut surface. Different arrangements and intensities of cross-hatching lines are used in practice to indicate different materials. Fig. 5 shows the symbols which are ordinarily thus employed in practice. It should be noted that there is no standard or universally-adopted set of cross-hatching symbols. Efforts have been made to have certain symbols standardized, but they have not been very successful. In view of this situation it is always desirable, unless there can be no question as to the material which a certain kind of cross-hatching on a drawing represents, to specify on the sheet just what material it does indicate. Cast iron is practically always indicated by light lines uniformly spaced. Wrought iron is shown by pairs of fine lines (Fig. 5) with a wide space between each pair. Steel is practically always indicated with alternate light and heavy lines. Fig. 5A, showing a longitudinal section of babbitt boxes of two types,

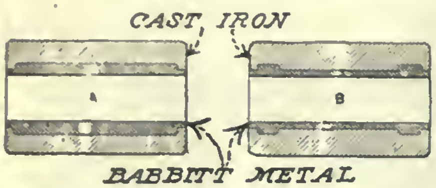

FIG. 5A—TWO METHODS OF BABBITTING A BEARING.

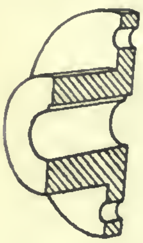
shows how the ordinarily-used babbitt symbol contrasts with that employed for cast iron. Incidentally note that the construction of B (Fig. 5A) is more economical of babbitt than that of A, and should therefore be employed during these times when bearing metals are so expensive.

Partial Sections

In a drawing where sectional views are used, no part is shown cut away from the main view; that is, the main view is shown complete with the location of the



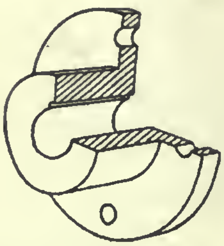


FIG. 6—HALF SECTION REMOVED. FIG. 9—QUARTER SECTION REMOVED.

cutting plane indicated on it, and only in the sectional view is a part of the object assumed to be cut away and discarded. For example, in Fig. 3 the complete steam chest cover is is shown in the plan view CDEF, and lt is only in Section AB that it is assumed that the portion BDFA is removed.

A half section view is one for which it is assumed that the object is divided by the cutting plane, which passes through an axis of symmetry, into two similar parts. Thus, in the perspective view of Fig. 4 the cutting plane is shown passing through the axis of the flange coupling. With the cutting plane and the portion H taken away, the half of the flange coupling which remains would

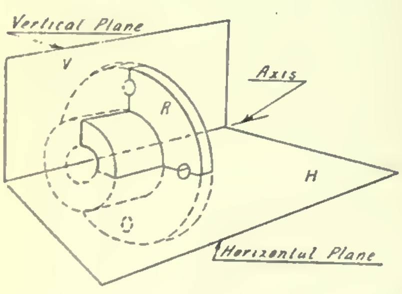

FIG. 7 FLANGE COUPLING SHOWING HALF SECTION.

appear as shown in Fig. 6: If this coupling is rendered in orthographic projection with the sectional view at the right of the end view, it will appear as reproduced in Fig. 7.

A quarter section is one wherein two cutting planes located at right angles to one another, and intersecting along an axis of symmetry, cut the object. Fig. 8 illustrates this definition as it applies to the flange coupling. With the cutting planes and the portion R removed, the cut coupling would be as diagrammed in Fig. 9. Then the corresponding working drawing would be arranged as suggested in Fig. 10.

Partial sections may be employed to advantage in many instances. A partial section is one wherefor it is assumed that some part of the object is cut away, so as to expose other parts within. The cutting plane with this sort of view need not be along any axis, nor need it have any particular relation to the symmetry of things in general. The draftsman merely cuts away the parts which interfere with a good view of the portions which he wishes to expose, and then completes his drawing on that basis. In Fig. 11 is reproduced a broken or partial sectional view of a clutch pulley, wherein a part of the pulley rim and of the cylinder C are, so it is assumed, cut away to show the parts inside. A splendid example of a broken section view is that of Fig. 12, wherein a part of the pipe is cut away, to disclose objects inside of it.

The cutting plane need not be a continuous plane. If it will be of assistance in showing the construction of the object under consideration, the draftsman may assume that he is cutting the object along any regular or irregular course. For example, it is desired to show the

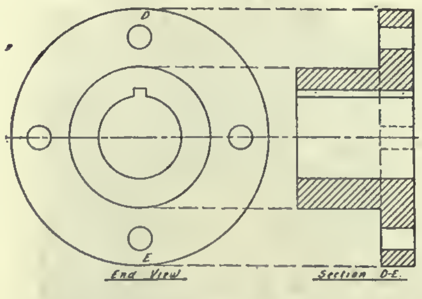

FIG. 8—SHOWING CUTTING PLANE OF QUARTER SECTION.

construction of the casting of Fig. 13 with two views, a plan view and a sectional view. To do this most effectively the draftsman must assume that his cutting plane follows the lines ABCD in Fig. 14. Fig. 15 gives a perspective illustration showing the position of the assumed cutting plane. The resulting sectional views are completed in the lower cutting plane. The resulting sectional views are completed in the lower part of Fig. 14.

ELECTRICAL PLANT IN STEEL WORKS

The uses to which electricity can be put for the driving of steel works plants are well known. says a correspondent in the Engineering Supplement of the "London Times," and it is not here proposed to seek new converts to electrification. But what is wanted to promote the most successful application of elec-

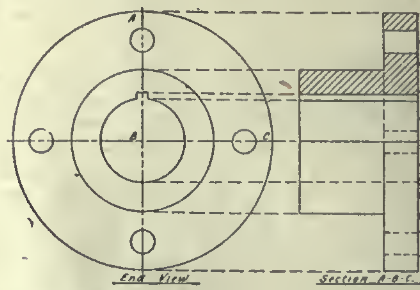

FIG. 10—FLANGE COUPLING SHOWING QUARTER SECTION.

tricity in steel works is a better and more thorough understanding of the conditions prevailing and their bearing upon the design, construction, and installation of the various plant details.

It is futile for the average electrical

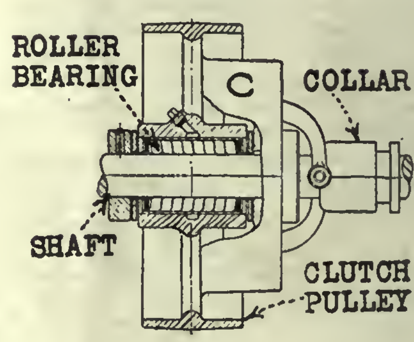

FIG. 21—ROLLER BEARING IN HANGER SHOWING COMPLETE CONSTRUCTION.

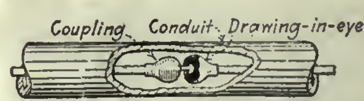

FIG. 12—BROKEN SECTION SHOWING PARTS WITHIN.

engineer who has never studied steel works conditions to attempt to design or issue specifications for plant to be used therein. Failure is certain. On the other hand it is of the highest importance that the steel works engineer in deciding upon the quotations for a particular piece of plant should proceed intelligently and make absolutely sure—first, that what he is asking is the proper type for steel works use; secondly, that he is being offered such plant by the manufacturer; and thirdly, that the details of the plant are such as to assure successful working under the stringent conditions imposed by steel works practice.

Steel Works Operations

To recount briefly the scheme of operations in a modern steel works—the scrap and pig arrive in trucks and are unloaded by magnet cranes either into the stockyard or into the charging boxes. In the former case there is the additional operation of removing from stock as desired and transporting to the charging boxes. The railway siding that brings in the trucks runs parallel to the line of furnaces, and between the railway and the furnace mouths run one or more charging cranes which transfer the charging boxes to the furnaces, upset them, and return the empty boxes to be refilled. The ingots, after being cast, are transported to the rolling mills, where they are reduced to the various sections required. From the start there is an atmosphere of incessant activity. The plant is at work day and night, and the machinery is in many instances running continually.

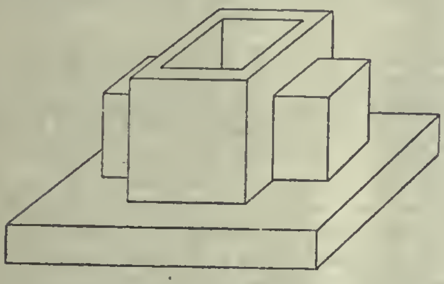

FIG. 13—PERSPECTIVE VIEW OF CAST IRON BLOCK.

The electrically-operated charging machine which conveys the charging boxes has as many as five controllers, all operated by one man. He has to run the machine up and down the line of furnaces, push out the arm of the machine horizontally to engage the charging boxes, give it a vertical lift, slew the machine round through 180°, adjust the height of the arm to the furnace mouth, push the arm into the furnace, turn it through 180° to empty the contents into the furnace, pull in the arm again, and reverse the process. These operations are not carried out singly, and two controllers at least may be working at one time to give their special motions. By electrical operation the speed of the cycle has been reduced to a very few seconds, and it is scarcely believable how quickly an operator can in so short a time move five controllers through their cycles. But while admiring the celerity with which operations are carried out, the electrical engineer must direct his attention to the extreme robustness which must be a characteristic of the electrical plant in order to enable it to withstand such rapid action.

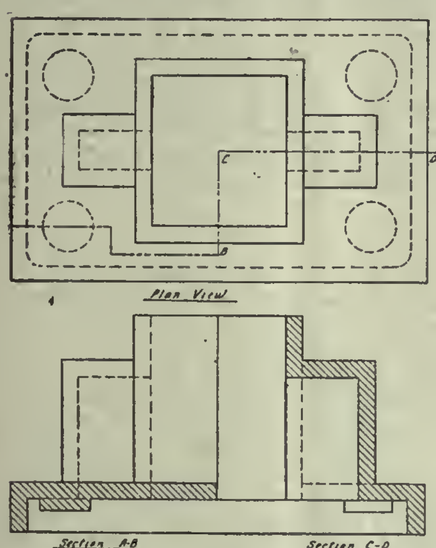

FIG. 14—NON-CONTINUOUS CUTTING PLANE.

Live-Roll Motors

As a further example, take the rolling mills. These are driven by large electric motors of extremely strong construction, and the ingots are conveyed to and from the mill after their various passes by rollers driven by special "live-roll" motors. A good criterion is obtained of the severe duty imposed upon the electrical plant in steel works when it is understood that often these motors are called upon to stop, start, and reverse something like 500 times an hour. If one of them breaks down, putting a train of rolls out of action, the mill may be stopped. It is therefore imperative that in the event of a breakdown the motor should be capable of instant repair. Further, the machine should be readily accessible for inspection.

The line taken in the construction of these motors in the case of the continuous current machine has been to split the shell so that the machine can be opened out in a few minutes and the armature removed for inspection, giving at the same time access to the field coils. In this way the continuous current live-roll motor is similar to the standard traction motor. In the alternating current machine the problem has been more difficult of solution. Success, however, has been achieved in the following way:—The shell has been split as in the continuous current motor, but it acts merely as a container for the machine proper. After removal of the bolts, permitting the top half of the shell to be removed, and also the bearing caps, the bearing bushes are exposed, each provided with an eye-bolt. By applying the crane slings to these two eye-bolts the rotor is lifted out, carrying with it the stator, which is in cylindrical form. After it has been conveyed to a convenient spot the rotor can be slid out of the stator and inspection or repairs proceded with.

There are, of course, numerous live-roll motors about the works and spare parts are provided, the motors being completely interchangeable. As an example of the thoroughness with which the details have been planned, attention may be called to the fact that the motor is designed symmetrically so that if the shaft shears at one end the whole machine can be lifted, turned through 180 deg., and bolted down again in the same place. The other end of the shaft is then available for the attachment of the half-coupling and the motor can be set running again. In this way a thoroughly reliable machine has been constructed. It is worthy of note that before the war these alternating current live-roll motors had not been made in this country, and only within the last few months have British electrical manufacturers tackled the problem with successful results. The same type of machine is now largely being used for other purposes in the steel works.

Enclosure of Motors

The matter of enclosure deserves special attention. Often motors in steel works are exposed to atmospheric conditions, to a considerable amount of dirt and dust, and, it may be, to steam. In inviting quotations for plant it is emperative that the steel works engineers should specify the conditions accurately, and in particular he should inform the manufacturer whether the motor is to be exposed to heat or whether it is to be put in the open air. There are many situations in steel works where high temperatures are encountered. Now, electrical plant is rated upon temperature rise, but if the initial temperature is higher than the standard, the ultimate temperature may reach such a point as to destroy the installation. This has often been a source of trouble in steel works practice. Another fault has been the ordering of machines for outdoor purposes, specifying them as "totally enclosed." But a totally enclosed motor does not necessarily mean that the machine is so constructed that it will not permit the entry of moisture. Where a weather-proof machine is desired, the attention of the manufacturer should be very carefully called to the fact.

Controllers form one of the greatest sources of trouble in steel works plant. By the incessant making and breaking of current heavy stresses are imposed upon the fingers, and to meet the stringent conditions a large number of breaking points must be provided on the drum. Heavy tips to assist in increasing the cooling surface are essential, for the larger the cooling surface the sooner will the arc at break be extinguished. The contact fingers and tips must be renewable, and it is essential that the same facility shall be extended to all other wearing parts.

Lifting Magnets

Perhaps the most striking feature of steel works electrification is the application of electrical lifting magnets, which in the last few years have been installed in surprising numbers. As an example of the economies that can be effected, one magnet has done in a day shift with one man the work that occupied three shifts of eight men in the ordinary scheme of operations. The magnets are sometimes used on jib cranes running about the yard, the crane being equipped with a small steam set generating the exciting current for the lifting magnet, sometimes on transporter cranes either in the stockyard or against the furnaces, but more usually on overhead cranes for loading the charging boxes. The adoption of the lifting magnet has revolutionized the haidling of iron and steel and has led to important increases in production and diminutions in labor costs. Incidentally, many of the cranes are now being operated by women.

In formulating a scheme for the handling of iron and steel it is not less important than in the previously mentioned instances that a thorough acquaintance with the conditions obtaining should be acquired by the engineers of both the purchasers and the manufacturers. Manufacturers who have made a study of the problem have on occasion found themselves in difficulties through the failure of the steel works engineers to realize the strenuous nature of their work. As an example, a magnet crane for a 52-in. magnet should be a 10-ton unit, but steel works engineers have asked, "Why do you propose to instal a 10-ton crane when the gross load will never be more than five tons?" The manufacturer has had in mind the fact that the crane will be working continuously, whereas in the majority of instances where cranes are installed the activity is far less pronounced than in steel works, and he has realized that a 10-ton crane is essential to reliability. Instances are on record where steel works engineers have preferred to purchase lighter cranes on the basis of a closer approximation to the gross load than that offered by the more experienced manufacturer. The result has been dissatisfaction, which, unfortunately, although due to a mistaken selection on the part of the purchaser, has put magnetic handling of materials into disfavor in that particular works.

In the smaller jib cranes, where an electrical generating set and switchboard is installed, the manufacturer sometimes finds a disinclination on the part of the purchaser to pay for proper electrical gear. Such apparatus should be thoroughly weather-proof, and in addition should afford the fullest protection to the operator. Ironclad switchgear, for example, is necessary, whereas in the past the open type of apparatus, being much cheaper, has found its way into use.

There is thus an imperative necessity for the closest co-operation between the manufacturer and the purchaser. No manufacturer should be penalized for offering plant which the purchaser deems too good for the job. Nothing is too good for steel works, and if the purchaser will bear this closely in mind in making his selection and will inquire whether the plant offered is being produced by a manufacturer thoroughly cognizant of the conditions prevailing, he is more likely to obtain plant with that high degree of reliability and strength which is so necessary for steel works drive. In the past it must be admitted that both manufacturer and user have sometimes been guilty of negligence that has led to failure of electrical machinery in steel works. The manufacturer has been ready to take orders without making himself fully conversant with the conditions to be met, while the steel works engineer has rejected offers of thoroughly satisfactory plant for others which had the sole advantage of lower price. Cheeseparing does not pay in steel works plant, and the saving of a few pounds on one machine may be followed by the loss of many thousands through reduction of output.

CANADA'S WORK ON MUNITIONS

On what a gigantic scale are the operations in Canada of the Imperial Munitions Board is indicated in an official statement that the total value of contracts for shells, raw materials and supplies of various kinds up to May 31 last was $1,200,000,000. No less than $1,000,000,000 had been paid out on account of these orders by the board to the same date.

Of this enormous expenditure shells accounted for $664,300,000, the total number of shells produced in Canada to the end of May being 59,390,000. These shells range in calibre from those for the eighteen-pounder and the 4.5 howitzer to the 9.2 howitzer.

Fifteen per cent. of the total expenditures of the British Ministry of Munitions during 1917 was spent in Canada, constituting a very substantial proportion when it is remembered on what an enormous scale is the manufacture of munitions in Great Britain itself, and how heavy has been her outlay in the United States.

Canada's Contribution Striking

In the report issued by the Imperial War Cabinet for 1917, the following statement is made:

"Canada's contribution during the last year has been very striking. Fifteen per cent. of the total expenditure of the Ministry of Munitions in the last six months of the year was incurred in that country. She has manufactured nearly every type of shell from the 18-pounder to the 9.2 inch. In the case of the 18-pounder no less than 55 per cent. of the output of shrapnel shells in the last six months came from Canada, and most of these were complete rounds of ammunition which went direct to France. Canada also contributed 42 per cent. of the total 4.5 shells, 27 per cent. of the 6-inch shells, 20 per cent. of the 60-pounder H.E. shells, 15 per cent. of the 8-inch and 16 per cent. of the 9.2-inch. In addition, Canada has supplied shell forgings, ammunition components, propellants, acetone, T.N.T., aluminum, nickel, airplane parts, agricultural machinery and timber, besides quantities of railway materials including no less than 450 miles of rails torn up from Canadian railways which were shipped direct to France."

450 Factories Engaged

The number of factories engaged in Canada in the production of munitions is 450. Of these 150 factories are occupied in machining the steel shells and assembling component parts which are supplied to them by the board, while 300 factories are producing component parts, which are forwarded to the machine plants to be made into the complete shell.

From 50,000 to 80,000 tons of steel, and from 1,500,000 to 2,000,000 forgings are handled monthly by the Imperial Munitions Board. To July 31 approximately 2,100,000 tons of steel had been received and distributed by the steel department of the board, resulting in the shipment to machining plants or for export of 75,000,000 forgings for shells of sizes ranging from 18-pounder shrapnel to 9.2.

The Imperial Munitions Board has also arranged contracts in Canada on behalf of the United States government, whereby Canadian manufacturers will undertake the machining of approximately 11,000,000 shells and the manufacture of 13,000,000 forgings.

CONSUMPTION OF COMPRESSED AIR

AN easy method of determining the consumption of compressed air by air-driven machines has been recently given by a writer in *Foundry*.

Desiring to secure information regarding the amount of compressed air required per mould by different sizes of foundry vibrators, a small air compressor was used with a shut-off valve located between the compressor and the tank and in the latter the air pressure was raised to 90 pounds. The valve was closed and with a stop watch the time was noted that elapsed for the vibrator to reduce the pressure to 70 pounds. It may be assumed that for all practical purposes this would be equivalent to 80 pounds mean effective pressure, the amount in most general use in foundries. To illustrate in ever figures, it will be assumed that the tank holds exactly ten cubic feet of air and that it takes the vibrator exactly two minutes to reduce the pressure from 90 to 70 pounds. Therefore it is figured that the vibrator used 10 cubic feet of air in two minutes. By actual tests it has been found that the average time the vibrator is working while the moulder is drawing a pattern is about 15 seconds and, therefore, we get eight moulds with 10 feet of air and the vibrator uses 1¼ feet of air per mould. This same principle may be applied to any air-driven tool or moulding machine and it is believed that the results are more nearly representative of actual conditions than theoretical calculations.

To remedy dusty concrete floors, a surface treatment of some kind should be applied to remove the surface skin which does not exceed 1-32 in., or properly to treat it. One way is to grind the surface by hand or power as a terrazzo floor is polished. Other methods are to apply liquid coatings of various kinds. One of the most satisfactory treatments is with boiled linseed oil thinned with petrol to such a consistency that it will penetrate the pores of the surface. If one coat does not cure the trouble generally two will. A second method is to clean the surface thoroughly and then apply a coat of silicate of soda or water glass, 40 deg. Baume, diluted one part to six of water, to seal the surface. Then wash off the excess which opens out the pores again and apply a second coat.

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

MACHINING OPERATIONS ON THE 155 M.M. SHELL

By P. Washington

OWING to the difficulty at this time of securing information as to the requirements in connection with the machining of this shell as regards varnishing and painting, etc., this article deals only with the machining in general.

However, it will give one a good idea of the type and general requirements. This shell can readily be kept within the required weight limits, it being obvious as when to take the weight. If a few shells, say, six, are machined first and accurate weight taken before and after each operation, this data will furnish all the information required.

Due to the lack of experienced and first-class operators, and inasmuch as these shells are readily handled, it is advisable to make each operation as simple as possible. Of course, the available machine tool equipment must be taken into consideration.

In preparing to manufacture this shell, the article entitled "Notes Regarding Preparatory Work in Shell Production," which appeared on page 51 of the January 17th issue of CANADIAN MACHINERY, will be found useful.

Cut Off Open End

1st operation (see Fig. 1).—Engine lathe or special cut-off machine. Two cut-off tools set opposite each other, the shell being held in a plain barrel chuck by means of four set screws. Gauging—Gauge depth of bore to make certain that shell will clean up on the base later on. (A definite distance should be agreed upon, and any forging below this limit should be rejected.) Gauge length over all and centre punch before this operation. Check same after this operation.

Centre Closed End

2nd operation (see Fig. 2).—Engine lathe with expanding mandrel having two sets of jaws—one set to grip shell at closed end and the other just forward of the open end. A special drill with no body clearance and a 60-degree point is used. The special fixture consists of a drill spindle, with ratch and pinion mounted in a casting, having a "V" slide to enable the operator to slide the fixture to the rear when placing or removing shells.

Rough Turn Body

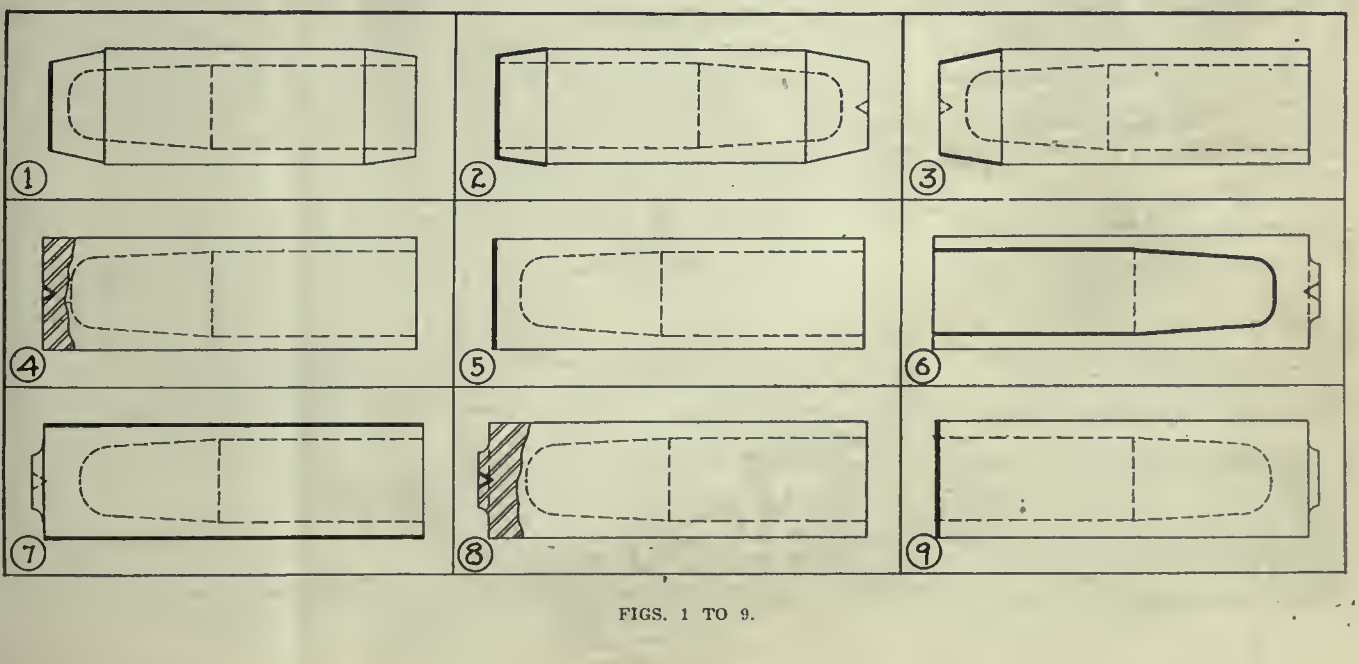
3rd operation (see Fig. 3).—An engine lathe is used. A mandrel to fit lathe spindle centre having three fixed hardened tool steel jaws set at a slight taper in a machine steel shank is used. The tailstock centre is applied to the centre in the closed end of the shell. Gauging—Gauge high and low diameter.

Bore

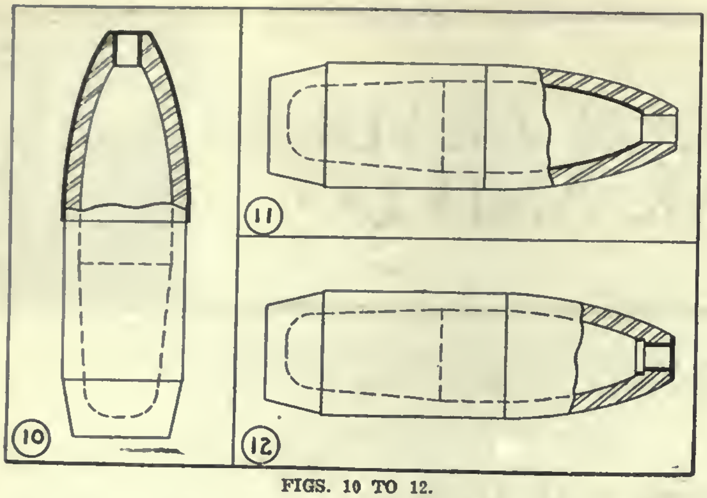
4th operation (see Fig. 4).—Rough and finish bore on a special boring machine or turret lathe. The shell is held in a clamp chuck. The first cutter is used to remove the scale from the bottom of the bore (should forgings run fairly close to finished contour this cutter may be omitted, otherwise its use is advantageous). The second cutters are for the straight part of the bore. The third cutters (old finishing cutters notched) are for roughing the taper and bottom of shell. The fourth cutters are for finishing the straight part, taper and bottom. Gauging—Gauge diameter and depth of bore.

Rough Face Base

5th operation (see Fig. 5).—The shell is held in a collet chuck, the bottom of bore being forced against a stop fixed in the centre of the chuck. This enables



FIGS. 1 TO 9.



FIGS. 10 TO 12.

the operator to set the tool, by means of another adjustable stop on the lathe carriage, the required distance from this stop. Special open end machines are very desirable for this operation. Gauging—Gauge thickness of base.

Re-Centre Closed End

6th operation (see Fig. 6).—This operation is carried out the same as operation 2, the same fixture being used. Gauging — Gauge depth of centre. Note—This operation is made necessary in order to secure concentric shells, i.e., by means of locating this centre from the bore, and then using this centre for finish turning this is accomplished.

Chamfer Body

7th operation (see Fig. 7).—Lathe or special open-end machine. Shell held in collet chuck with stops, as explained in operation 5. A flat forming tool is used. Gauging—Gauge form (angle) and length of taper. Check diameter across base.

Bevel and Face Open End to Length

8th operation (see Fig. 8).—Lathe or special open-end machine. The shell is held in a collet chuck, being forced against a stop at the bottom of base. A set stop (adjustable) on lathe carriage fixes the length of shell. A block tool holder is used; a flat forming tool and cut-off tool (wide enough to require no cross-feed) is used. Gauging—Gauge form (taper) and length of bevel, diameter across open end. Check length of shell.

Finish Face Base

9th operation (see Fig. 9).—This operation is carried out the same as operation 5. The gauging is identical.

Nose In

10th operation (see Fig. 10).—A hydraulic press is used. The open end of the shell is heated in an oil or gas furnace, an oil furnace being preferable. The shell is then placed in the press against three locating pins, the die brought down, and the shell nosed in. Although cast iron dies are successfully used, machine steel ones stand up to the work better. In either event they should be water-jacketed. Two upright stops (one on each side of the press) determine the length of shell. Gauging—Gauge diameters of fuse hole (at top and bottom), length of fuse hole, contour of nose and over-all length of shell.

Finish Inside Contour

11th operation (see Fig. 11).—This operation is carried out the same as operation 8. A forming cutter is used. It is held in an oval (section) bar, with a roller at the end of the cutter in line with it, which brings this cut in line with the bore proper. Gauging—Gauge length of fuze hole.

Ream Fuse Hole

12th operation (see Fig. 12).—The shell is again held, as in operation 8. A four-way or turret tool post is used. The first tool rough bores the fuse hole and faces it to length; it carries a stop which strikes the bottom of the bore. The second tool recesses the rear part of fuse hole. The third tool reams the fuse hole (part to be threaded).

Finish Turn Body

13th operation (see Fig. 13).—Engine lathe with collet chuck to grip base end of shell, expanding centre at tailstock end to fit fuse hole. Stops on carriage and lathe to determine correct diameter. Gauging—Gauge high and low diameter.

Finish Turn Shoulder and Nose

11th operation (see Fig. 14).—Engine lathe with shell held, as in operation 13. Cam profiling attachment at back of lathe with roller guide arm on carriage. Gauging—Gauge high and low diameter of shoulder and form gauge for nose profile.

Thread Fuse Hole

15th operation (see Fig. 15).—Special single purpose thread miller or engine lathe with collapsible tap. Gauging—Gauge high and low diameter. Thread gauge for form and size of threads.

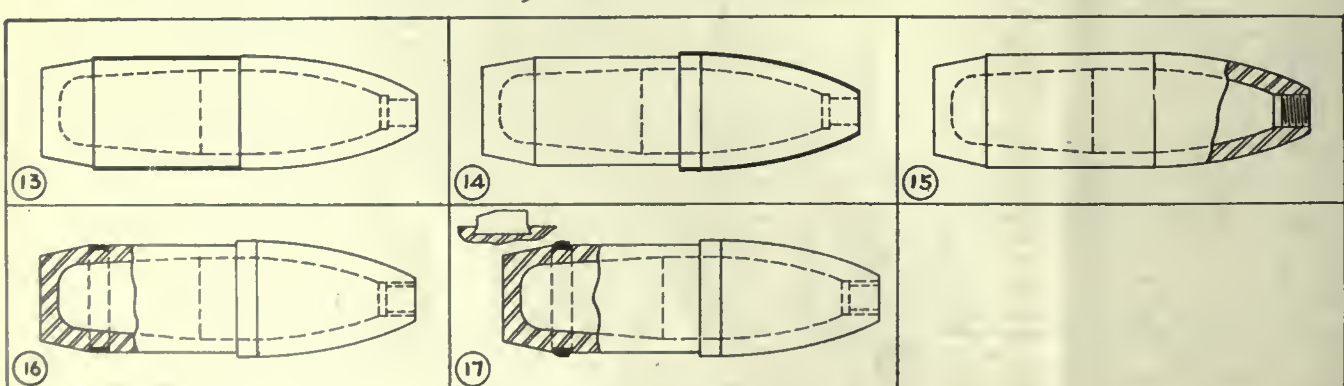
Groove

16th operation (see Fig. 16).—Special open-end machine or engine lathe with collet chuck. A circular grooving tool is used. The two undercutting tools are mounted in holders, which have racks cut in their shanks. By means of a gear wheel to mesh with these racks the undercutting tools are fed forward at the desired angle and width. Gauging—Gauge angle of undercut, width of groove, distance of groove from base, high and low diameter of groove.

Turn Band

17th operation (see Fig. 17).—Same equipment as used in operation 16. Two flat forming tools—one for roughing and the other for finishing. Gauging—Gauge high and low diameter of band and form.

The presence of acid in oil or grease is very deleterious to the bearings, especially ball bearings, as it causes more or less rapid corrosion. To test oil for acid, clean a piece of sheet copper, cover it with the oil and let it remain for several days. Should a green deposit form on the copper it may be concluded that acid is present. Lubricating oil or grease should be absolutely neutral in its character.



FIGS. 13 TO 15.

MILLER WAS USED WITH SEMI-AUTOMATIC FIXTURE ON THIS JOB

By D. A. THOMPSON

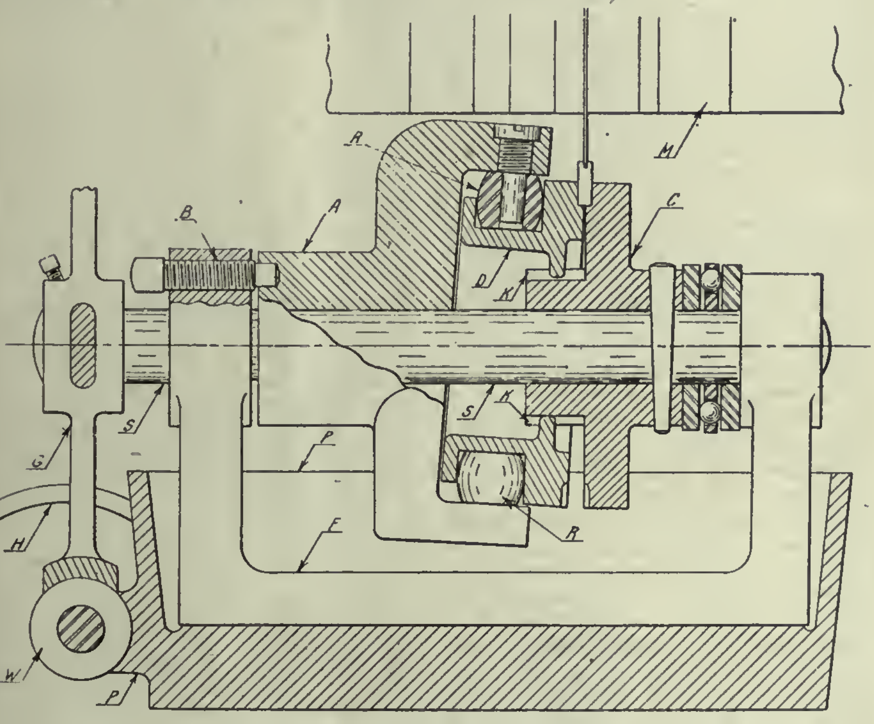
THERE is a device used largely in Canada and the United States in the training of marksmen that fits inside the bore of the service rifle. The blow of the hammer is transmitted to a tempered rod sliding in bearings in a thin brass tube; one end of the rod is pointed, and, when the gun is fired, strikes a miniature target set up at a correspondingly reduced distance from the muzzle of the gun. A spring returns the rod to its place inside the tube. The device is used in the instruction of recruits in sighting, aiming, and general handling of the rifle and by more experienced riflemen to keep in practice in times and places that the outdoor ranges are not available. Economy is a feature for no ammunition is used—instructors say that the practice is the best possible without ammunition, only the recoil and the noise being absent.

The shop had taken a contract to manufacture parts for some twenty thousand of these devices of one make. One of the jobs was the milling of a slot 1-16 in. deep in the ends of pieces of ¼ in. steel; at the beginning it was intended to do this on the five spindle screw machine that turned out the parts, but a few days' running disclosed conditions that made it advisable to do the slotting separately. As there were nearly 150,000 pieces to be handled some quick way of loading and unloading was imperative. The fixture for this work is shown by the drawing.

A Miller Was Used

A hand miller was selected for the job. The fixture was fastened to the table directly under the arbor and parallel to it with power for rotation furnished by a ¾ in. belt to a pulley H on the worm shaft which was on the free end of the fixture overhanging the table. The worm W drove the gear G fastened to the main shaft S on which were mounted the work holding parts. The casting F provided two bearings for the shaft and in turn was bolted to a pan P that served also as a base and a support for the worm shaft.

The work holding mechanism consists of a casting A kept from revolving by the set screw B, a loose fitting ring D driven by the disc C which is pinned to the shaft, there being two keyways on the inner hub of C in which projecting portions of D fit loosely. A groove or race in D is the means by which D is moved closer or farther from C, accommodating varying sizes of stock and giving different grips on the work. Three rollers R are pivoted on screws in A and travel in the race way. Set screw B is turned to bring D nearer to C.



FIXTURE TO AID IN THE RAPID CLAMPING AND RELEASING SMALL PIECES IN THE MILLER.

From the drawing it will have been noticed that D and C are not in parallel planes—this is meant to be so, and is the somewhat unique feature of the fixture. Two of the rollers R are placed below the shaft, 60 degrees each side of the vertical center line and both of them back of the upper roller, which arrangement tilts D and provides a real grip at the top only. Twenty degrees each side of the top the work may be pulled out with the fingers. Advantage is taken of this to put an ejecting finger between the two discs (on a 45 degree slant) which unloads the work pieces into a chute without any attention. A boy stationed on the "closing" side loads the fixture which has holes spaced on ⅜ in. centers.

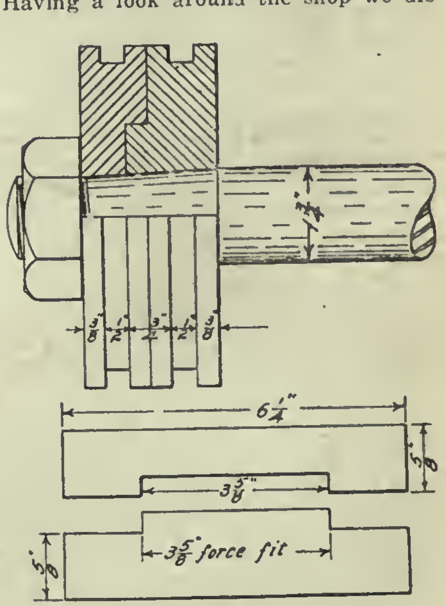
The operation was practically continuous. Aside from loading the boy had little to do. At the bottom the work recesses were cleaned by passing through the liquid in the pan—an overflow and the ejecting finger on the far side are not shown. A drip can supplied lubricant to the cutter which is on the arbor M. To relieve the friction from the set screw a ball thrust bearing was installed. When this job was finished a new set of holes were put between for another similar job.

EMERGENCY REPAIR TO PISTON

By J. H. HOULDSWORTH

EMERGENCY repairs are frequently an important factor in maintaining the efficiency of a machine shop or power plant. Under certain conditions it is very often necessary that repairs be made at once to avoid shut down of the plant or one of the departments. Where equipment must be operated without rest the maintenance of such requires the most careful attention on the part of the engineer in charge.

The accompanying sketch shows the repairs made to a piston when the same was required at a time when all foundries were closed. This piston was used in a pump which was operated twenty-two hours per day, and the break developed at a time when a replacement in the ordinary way was impossible owing to the fact that it happened about noon on Saturday, with all foundries closed for the week. Repair was absolutely essential so some method had to be adopted to get the pump running again. After dismantling the pump it was found that the rod was also bent. The latter was not so serious, as the straightening was soon accomplished. Having a look around the shop we dis-



PISTON REPAIR SAVES SHUTDOWN.

covered a couple of old balance weights with a diameter of 7½ inches and a thickness of 2¼ inches, from which we made a very satisfactory piston as shown. We had two lathes available, so one was set to work to rough down the weight to about ⅛ inch of the required diameter of 6¼ inches, and the hole bored ⅛ inch smaller than the small end of the taper. The other lathe was then started on the second casting, this being roughed in a similar manner, with the exception that the hub of one was made a force fit for the other. One of the pieces was then removed and pressed into the other without removing the latter from the face plate. The two were then held firmly together by means of suitable clamps, and the center hole bored out to fit the taper end of the rod. After securing the piston on the rod the rod with the piston was placed on the lathe centers and the head finished to the proper diameter and the piston ring grooves turned in. We were able in this way to have the pump working before night, thus avoiding the necessity of obtaining a new pump. The pump was shortly afterwards replaced by one of greater capacity, and the old one sold, but the latter is still in good working condition, no trouble having developed from the impromptu repair.

BURNLEY'S SOLDERING PASTE

By M. E.

A flux for use in soft soldering has been sold on the market under this name for a number of years and has given good satisfaction. It is used in the same manner as chloride of zinc flux, but is not supposed to corrode the work upon which it is used. In this respect it is superior to the usual liquid chloride of zinc flux, but is not entirely free from corrosion as it is believed that there is nothing which is actually non-corrosive when used as a flux, otherwise it would not act as such.

The particular advantages of this flux are in its portability (there is nothing to spill) and the ease with which it can be used. The manner of making it is to first make a saturated solution of chloride of zinc of a neutral character. The two requirements are absolutely necessary, and are easily accomplished. To make the saturated chloride of zinc solution, metallic zinc is dissolved in strong muriatic acid. Any crystals which form in the bottom of the dissolving vessel are dissolved in just enough water to take them up. By the use of strong muriatic acid hydro-chloric) acid, this is accomplished. In other words the chloride of zinc solution is as strong as it can be made.

The neutral condition of the solution is produced by having an excess of the metallic zinc in the liquid when it is being dissolved in the muriatic acid. In other words, there must be more than enough zinc used to take up all the muriatic acid. When the acid ceases to act, which may be known by the cessation of gas bubbles from the zinc itself, the action has stopped and no more zinc will dissolve. At this point there should be more or less zinc left in the bottom of the vessel in which the dissolving has taken place. The whole should be allowed to stand for an hour or more in order to give the acid a chance to dissolve all it will. The solution, then, will be neutral, for the reason that the acid has dissolved all it can and if strong muriatic acid is used, a saturated solution will have been obtained. This solution of course, is the regular chloride of zinc soldering flux, but it is made in the right manner. The common error found in making it is to have too much water present and a quantity of free acid which of course, means muriatic acid not used up on the zinc. This interferes with action in soldering. It also corrodes the metal that is soldered. There has been obtained therefore, a saturated and neutral solution of chloride of zinc. This is the base for the manufacture of the paste and is the flux which acts on it.

The chloride of zinc flux thus produced is mixed with a grease and the paste is ready. For the grease, the inventor recommends "vaseline" or "petrolatum" both of which are the same thing under a different name. Petrolatum is the cheaper of the two. The proportions of the grease and chloride of zinc flux used are as follows:

Saturated Chloride of Zinc Solution 2 oz. (fluid.)

Petrolatum or Vaseline 1 lb.

These two ingredients are mixed by violent stirring until the mixture begins to thicken when it is poured into the receptable in which it is to be used. If any other grease is to be used, the same proportion is to be employed.

This paste was originally patented by Wm. Burnley of Miamisburg, Ohio, and James and Burnley of Cottonwood Falls, Kansas, and the patent was granted on Aug. 9th, 1918. It has about a year longer to run before it elapses

MACHINE SHOP HEATING AND VENTILATING

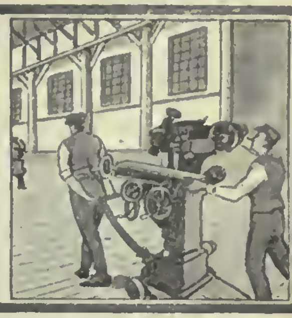
By "Dale"

Considerable difficulty is experienced in arranging for the heating and ventilating of the single storey sheds with saw-tooth roofs now in universal favor for light machine shops. The wide expanse of surface exposed to the weather in such buildings makes the task of maintaining a comfortable working temperature difficult on cold days, and while roof ventilators and fans afford adequate ventilation in summer, they are invariably put out of action in winter on account of the excessive down draught of cold air, whereupon the air in the centre of the shops becomes stagnant and impure. But satisfactory hygienic conditions are essential to the maintenance of efficiency; hence some method must be devised to supply warm, fresh air in the winter, and cool air in the summer to all parts of the building. A good arrangement has been in work for two years past in a well known English plant at Birmingham. It consists of a number of cupola-shaped heaters (four in this particular case) distributed about the shed, each of which draws air by means of a 15-inch motor-driven horizontal propeller fan, located at the down inlet pipe protruding through the roof, passes it through a battery of steam pipes, and ejects it at the floor level, whence it rises and circulates through the building. The down pipe is fitted, just below the roof, with a swinging damper which can be moved so as to block the admission of outside air and allow the warm air from inside the shop to be passed and repassed through the heater. This is very beneficial on cold mornings, as it enables the air to be raised to a suitable temperature in a short time, whereupon the damper can be moved back and the temperature maintained with the cold air outside passing through. This feature is a distinct improvement on many other types of heating apparatus. The steam is supplied to the heaters from a vertical boiler 9 ft. high by 3 ft. 9 in. diameter (which if worked at 80 lb. per sq. inch, is capable of serving eight heaters in the coldest weather) through 1 in. branches from the main steam pipe, and is trapped at the outlet with a steam trap of the float type, in order to prevent the passage of uncondensed steam. The condensed steam, after leaving the trap, is forced along a ¾ in. pipe, past a check valve, into the main return pipe, which conveys it to the boiler feed t

The legs of the heater are utilized as a means of connection to the stem and drain pipes. Valves are fitted to both pipes of each heater, so that one can be out for repairs without disturbing the others. The temperature can be varied by altering the steam pressure, by varying the quantity of steam passing through the steam valves, or by means of the motor regulator, the latter being arraned to give four different speeds. During the warmer weather, when it becomes unnecessary to use the heating part of the apparatus, the fans are used for ventilating only. The impure air escapes through the interstices in the doors and between the valley gutters and the lower purlin on the glazed side of the roof. By reason of the pressure inside the building being slightly greater than that of the atmosphere, all leakages are from the inside outwards, and hence draughts are prevented. The cost of this method of heating and ventilating compares very favorably with any proprietary system, and at the same time meets all the requirements of a modern heating and ventilating plant.

Matheson, Ont.—The construction of a complete system of electric light and power at an approximate cost of $10,000 is having the consideration of James A. Lyttle, deputy clerk of the municipality and ratepayers of the town.

DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

GRINDING AND FINISHING MACHINES

A GRINDING and finishing machine of high efficiency is shown herewith. This machine, made by the Blevney Machinery Co., Greenfield, Mass., embodies their two-belt principle of operation. A heavy and substantial cast iron frame of box pattern carries a polishing head with three pulleys, over which the corrugated leather and cloth abrasive belts are run. These pulleys operate in bores and frames having suitable adjustment for controlling the travel of the belts with provision for automatic regulation of the belt tension.

The patented corrugated leather belt is driven from the central pulley around the small idler pulley at a speed of 7,000 ft. per minute. The cloth abrasive finishing belt is placed over the cushion belt running over the idler pulleys in each end of the polishing head.

The table to which the turret is attached is vertically adjustable by a handwheel. When the machine is in operation this table is given a side oscillating movement, adjustable to suit the different classes of work.

The cloth abrasive belts do away with all centrifugal action upon the finishing grains where they are under strain, and as compared with the disc grinder they provide a uniform speed for each grain, the disc grinder grains being subject to different speeds on account of their location at different points from the center of the disc.

The productive powers of these machines are made possible through the use of the two-belt system. The corrugated-leather cushion belt runs at 7,000 ft. per minute and the cloth abrasive finishing belt which runs over the former operates at a slightly increased rate of speed due to the enlargement of the driving pulley which is increased in size by twice the thickness of the cushion belt; the increase in speed being about one and a half inches on each revolution of the main pulley. The increased speed of the cloth abrasive belt is neutralized in operation when pressure is applied behind the belts with the result that the travel of the abrasive belt is somewhat retarded at point of work so that it must curve into high and low sections following the corrugations in the cushion leather belt. In this manner high points for cutting and low points for chip recess are obtained. After the belt passes point where work is held, it expels the chips and resumes its normal position.

By means of this process the chips are disposed of immediately as generated or cut instead of being rolled along the face of the work scratching and defacing it.

GRINDING AND FINISHING MACHINE

OIL BURNER

To obtain the best results from fuel oil, it is essential that the right kind of burner be used and it be properly installed. An oil burner in order to give satisfaction in operation, should be designed with the following features: to secure thorough atomization of the oil, to operate without causing oil opening, to be under complete control of the operator. The oil burner illustrated herewith has been designed by the Foundry Equipment Co., Cleveland, Ohio, with these points in view.

SECTIONAL VIEW OF OIL BURNER

The Coleman Oil Burner is unique in the manner in which the oil is atomized and mixed with the air. The air is sent from the main air chamber to a hollow brass stem. The oil is sent around this circular stream of air, and at the end of the brass stem, which controls the air supply, the oil is forced into the air stream at sharp angles. This causes a breaking up of the oil into small particles and produces a primary mixing with the air. A second and outer stream of air, cutting through the primary mixture, produces a further atomization and furnishes the proper combination of oil and air for complete combustion.

The burner connections provide for a one-half-inch oil line, 2-inch air line, giving a wide range of both oil and air.

Perhaps the most interesting feature in connection with this burner is the double mixing of air and oil which takes place in the burner. This is due to the arrangement by which a circular stream of oil flows between two air supplies, one on the inside and one on the outside.

DRILL GRINDER

The Grand Rapids Drill Grinders illustrated herewith are made by the Grand Rapids Grinding Machine Co., Grand Rapids, Mich. These machines embody several features of interest and value. A properly constructed spindle and a rigid and heavy housing are prime essentials for satisfactory grinding machines. The housing is part of the main frame casting. The spindle is made of 60 to 80 point carbon, hammered crucible steel, hardened ground and running in ring oiled phosphor bronze bearings, easily adjustable for either radial wear or end play, of simple construction. The bearing is dust-proof—a most essential point for any grinding spindle.

The drill holder proper is so designed that either straight shank or taper shank drills of standard type can be ground, and drills with enlarged shanks or drills mounted on quick change sockets can be ground with equal facility and without any changes or extra adjustments of any kind.

Lip-rests have caused more trouble in twist drill grinding machines than all other features combined. The lip-rest on this machine is really four lip-rests in one, as it can be put on so as to use either edge for the drill supporting edge and it can then be reversed top for bottom, and can in that position again be reversed so as to give four distinct settings, and at the same time there is an adjustment up and down to provide for wear. It is impossible to get the lip-rest on wrong, and should occasion require, it is so simple in its construction that any user can easily make a duplicate without much danger of going wrong.

A swinging arm with a diamond mounted therein and convenient means for adjusting same in the process of truing the wheel, is provided. In the case of double holder machines, a truing device is furnished for both wheels, and a diamond is a part of the standard equipment furnished with each device.

In connection with the truing device, there is provided a stop, in the form of a track on a movable section of the wheel hood. As the diamond is advanced into the grinding wheel in the process of truing it, this movable section of the wheel hood with its track is advanced an equal amount, hence it always remains a fixed distance from the face of the grinding wheel. A circular stop on the front of the drill holder abuts against the track referred to and rocks in the process of swiveling the holder. It is so adjusted that it brings the lip-rest into that extremely close proximity to the wheel, which is necessary for a perfect grind. At the same time, it is impossible to get the front of the holder or the lip-rest into the front of the grinding wheel. where it could be ground off.

Drills working on tool steel require very little clearance and a strong cutting edge. Those on soft grey iron require much greater clearance and do not require as strong a cutting lip. For maximum service, it is necessary to be able to rapidly adjust clearance and do so without danger of getting the rest of the adjustments out of order. In this machine nothing has to be clamped and nothing has to be tightened up. It is only necessary to turn a small hand wheel which rocks the holder proper in its swivel bearing. It canot get loose, nor slide up and down in its bearing during the process of adjusting clearance.

The only adjustment necessary is that necessary to accommodate different lengths of drills. No calipering and separate settings for individual diameters is required. No machine is more simple in its operation or efficient in service.

On wet grinding machines the end of the drill being ground is flooded by a stream of water or coolant 1½ inches wide and about ¼ inch deep, which drops directly on the point of the drill without any force. It is carried to the special flat nozzle through ¾-inch bore. Hoods, waterpan and guard are so arranged that they keep the water in the machine and off the floor. All pump bearings are above the water line and it is driven by a flat belt without the necessity of any idler pulleys.

Niagara Falls, Ont.—The National Abrasive Co. will start erection of a plant here at once.

DRILL GRINDER WITH PAN AND COOLANT RESERVOIR

DRILL GRINDER

HEAT-RESISTING PAINTS

By Mark Meredith.

The best heat-resisting paints are made from hardened asphaltum or pitch, dissolved in a fluid solvent; whilst for temperatures below the boiling water, casein, animal albumin and alkali silicates have given good results, writes a German authority. Pyroxylin varnish is very durable, but browns when heated, and can only be used when in admixture with black body colors. The following preparations are worthy of mention.

Roman Prasser's Recipe.—Equal parts (40) of pigment and spirit varnish (compounded of 1 part of bleached shellac in 7 parts of spirit) are intimately mixed with 1 part of camphor and 5 parts of bleached oil varnish. The article to be coated is brushed over several times with a mixture of gypsum and spirit varnish, flatted and painted over with the above preparation, being finally polished lightly with shellac varnish. This paint will stand the heat of boiling water for some time, but browns on prolonged exposure and peels off.

G. M. Neisel's Recipe.—Solid fats or fatty acids are distilled at 250 to 300 deg. C. with superheated steam. The residue being mixed with about 10 per cent. of red lead and 2 per cent. of litharge, treated with superheated steam at 400 to 500 deg. C. and thinned down at 150 to 200 deg. C. to workable consistency with linseed oil. As an alternative method the dilution with linseed oil is replaced by blowing in 25 per cent. of petroleum vapor, and then diluting with the crude benzol or other dilutent when sufficiently cool. The product is said to dry with a glossy surface, and to stand a dry heat of 500 deg. C. or damp heat up to 250 deg. C. As a matter of fact, an asphaltic substance and especially the distillation residues from fats (bone pitch, etc.) are capable of resisting high temperatures, and are used for stoving enamels.

Meyer's Recipe.—Residues from the distillation of fatty acids are heated to about 500 deg. C. with lead oxide and lead peroxide for three to four hours until thoroughly combined, the mass being dissolved in mineral oil and thinned down with turpes.

Bethisy's Recipe.—The mass consists of nitro-cellulose and a solution of calcium chloride in amyl acetate, with an addition of ether, alcohol, alum, talc, asbestos or mica, elasticity being imparted by vaseline oil or lavender. Celluloid varnishes are capable of standing a certain amount of heat.

Selmay Meyer's Recipe.—A heat-resisting varnish for iron ware, especially iron stoves, etc., is prepared by mixing powdered liver of sulphur, cyanide of potash, bicarbonate of soda, and sufficient cassel brown to give the desired color, and the mixture is saturated with alcohol. The pulp is passed through a sieve to remove coarse particles, and after being applied to the metal is exposed to a temperature of 200 to 300 degrees C. Other fireproof pigments may be submitted for the brown. This preparation is an enamel rather than a paint, but will stand heat very well.

Syracuse Tar.—A mixture of finely ground alum, asbestos and borax or boric acid is stirred into melted coal tar, the proportions being 60 to 65 or 40 to 50 parts of tar, 8 to 4 to 2 to 8 of alum, 20 to 5 or 38 to 30 of boric acid, 12 to 5 or 20 to 13 of borax, and 5 to 8 of asbestos. The idea seems to be that the salts will sinter together under the influence of the heat, the tar being presumably carbonized.

Avenarius' Recipe.—Ten parts of alkali silicate are heated under pressure with 25 parts of casein, a pasty mass being formed. This liquid is mixed with 0.2 part of carbonate of magnesia and 0.1 parts of borax, to increase the heat-resisting properties, whereupon 0.15 part of zinc oxide, 0.3 part of sodium phosphate and a suitable quantity of lime and earthly pigment is added to give covering power. For use, the mass is thinned with boiling water, and is said to stand a temperature of 100 deg. C. (212 deg. F.).

Fairweather's Recipe.—Equal parts of silicon carbide and semi-fluid alkali silicate are mixed together, 3 to 10 per cent. of chalk being added.

Hall's Fireproof Recipe.—This paint consists of moist silicate of magnesia, 5½ of dextrin, 5½ of gypsum, 2 of chalk, 2 of alum, and 1 of common salt. Four parts of this powder are mixed with three of boiling water for use. This preparation and the preceding one owe their "fire-resisting" properties to the sintering of the salts when heated.

Eymer's fireproof varnish is compounded of a mixture of alkali silicates with asbestos or other fireproof material and vegetable or mineral oils, or oily substances like glycerine.

Give a couple of coats of a good washable distemper, upon which should be given two coats of oil paint, the first somewhat flat and the last with a little oak varnish added to it. Painting on galvanized iron is at all times difficult, and there are various preparations on the market specially made for the purpose. If you do not care for the water paint plan try the following:—First go over the work with a wire brush so as to roughen the surface, then apply a coat of red lead well brushed out and mixed thin with boiled oil and turpentine. You will, of course, only mix just sufficient quantity of the red lead for the job, and will take care to stir from time to time while in use, as the red lead sets quickly. If there is much of the work to be done, we should recommend you to use orange lead instead of red lead, as although the two are practically of the same nature, the orange lead is a good deal lighter, and hence does not settle so quickly. You may take it that everything despends on the priming coat, and if this is satisfactory, the two or three coats upon it will hold well. The washable distemper in our experience gives as good a result as anything, and is much cheaper than the red lead system.

MEN AGAIN CONFER WITH RAILWAY WAR BOARD

Railway shopmen are returning to Montreal at the end of this week or the beginning of next to confer with the Canadian Railway War Board as to certain adjustments in the McAdoo schedule which the Federated Trades of the locomotive and car shops of the various Dominion railroads desire. The new amendments to the McAdoo schedule arrived at by the Permanent Wages Board appointed at Washington have not met the situation so far as the shopmen of Canada and the United States are concerned, and on both sides of the line it is expected that negotiations will proceed for the adjustment of wages more to the satisfaction of the men.

The varying conditions under which the different trades are required to operate makes it very difficult to establish a schedule of wages that will be suitable and acceptable to the many employees. Some further readjustment will be necessary to remove the disparities, when the same are sources of dissension among the different classes of workmen. While the conditions of the McAdoo award are generally satisfactory to railroad men throughout Canada, it is thought that some slight readjustment could be made to avoid unnecessary friction.

MANUFACTURERS HAVE RAISED PROFIT UNDULY

The Canadian Railway War Board announces that a detailed study has been undertaken which will show not merely the increase in the cost of railway haul in the manufacture of necessaries of life, but will go into the actual cost of the labor and raw materials in these articles, with a view to proving that while railway rates have increased possibly 30 per cent. since the war began, while railway costs of operation have increased by a larger percentage, manufacturers have actually increased their rate of profit out of all proportion to the actual increase in their cost of production.

The War Board gives the following list: Boots and shoes have risen in price since the war began 100 per cent.; beef, 35 per cent.; clothing, 50 per cent.; coal, 100 per cent.; cordwood, 100 per cent.; flour, 90 per cent.; gasoline, 100 per cent.; hardware, 100 per cent.; pork, 75 per cent.; sugar, 80 per cent., and tobacco, 50 per cent. The roads are paying now a 100 per cent. higher pay roll; 210 per cent. more for axles; 110 per cent. for brass castings; 200 per cent. for malleable castings; 100 per cent. for coke; 157 per cent. for iron and steel bars; 153 per cent. for fir; 80 per cent. for oak; 100 per cent. for pine and spruce; 130 per cent. for oil fuel at Montreal; 32 per cent. for oil fuel at Vancouver; 30 per cent. kerosene; 125 per cent, for steel tires; 100 per cent. for cleaning waste; 200 per cent. for lubricating waste, and 90 per cent. for cast iron wheels.

Toronto, Ont.—The British Forgings, Limited, contemplates a $15,000 extension to plant.

Should Be No Post-War Slump in Machine Tools

Great Bulk of Special Purpose Machinery Will Not Come Into Competition With General Purpose Equipment After the War—One Continuous Operation the Hardest Service For Any Machine

By J. H. RODGERS, Associate Editor "Canadian Machinery."

CONSIDERING the large volume of machine tools that are now involved in the production of munitions it is not surprising to hear many questions regarding the future of such equipment and as to their effect on post-war machine tool activity. To anyone unfamiliar with the work performed in connection with shell making the problem might well gladden the heart of the pessimist, but to those better acquainted with the duties required on this class of work, the outlook in this direction is much brighter than one would at first suppose. Had the war been of short duration the possibilities for a slump in machine tool activity would have been more favorable than the prospects now before us, and the more the war is prolonged the more certain will be a normal continuance of pre-war activity.

Business cannot possibly be maintained at the present high level when peace is declared, but apart from an expected period of readjustment we may reasonably anticipate a resumption of machinery activity such as existed prior to the opening of hostilities.

Inception of the Industry

During the early months of 1915, when the manufacture of munitions on a comparatively large scale was given initial consideration, the manufacturers in this country—although very enthusiastic—were somewhat skeptical about undertaking an enterprise so remotely foreign to anything previously experienced. The almost total ignorance of those interested was one of the primary causes of the initial delay in establishing the industry, as at that time it should be remembered that few in this country looked for more than a few months of shell making owing to the belief that the war that had been precipitated so suddenly would terminate as rapidly. With this thought in mind those firms that had received the initial contracts, guided by previous experiences in engineering activities—little reliable information being obtainable relative to accepted practice in munition making—commenced planning and buying available equipment, and also ordering additional machinery (invariably of the standard type) for the machining of the first contracts placed for shrapnel shells.

It may readily be seen, therefore, that practically 100 per cent. of the tools used on the initial orders were of a type that might subsequently be easily used for ordinary domestic enterprise. In some respects it might be stated that this was a feature that influenced the purchase on the part of those making the shells. It is at this point that a short war might have been considered as an influencing factor on what would then have been post-war conditions.

Early War Conditions

The number of machines that had been acquired or ordered during the first six months of 1915 was undoubtedly large in proportion to the general requirements under normal peace conditions. Bearing this in mind, we might have looked for a relatively quiet period following an early peace, as the bulk of the machinery had been manufactured under ideal conditions, with the best of materials and workmanship, built to stand up to the best engineering practice of the day, and in keen competition with many other makers. In the belief that the war would not be duly prolonged, the same high grade work was performed on those tools ordered for the pioneer work.

It is therefore obvious that, had the manufacture of shells closed within the first year, the greater percentage of the machine tools then employed would have been in fairly serviceable condition and could have been profitably utilized for ordinary commercial work, but the long service imposed on these and subsequent equipment will mean only one ultimate result—the scrap pile—as a temporary resting place before being again converted into more useful material through the medium of the cupola or one of the several types of furnaces.

Special Machine Development

Few factors have had a greater influence on the future of the machine tool industry than the inability of the builder to supply the primary demands of the pioneer shell manufacturers. If standard tools could have been obtained in sufficient numbers to satisfy the early requirements it is doubtful if the remarkable record that has been attained would ever have been accomplished. It is due, very largely, to the fact that shell makers were virtually forced to take the initiative and utilize their own individual resources to meet the situation that increased in magnitude every week—almost every day—that we have been able to achieve the results of the past several years.

Unable to secure the desired machinery, and feeling the increasing tension from day to day, the dormant qualities of the engineering profession gradually awoke from the stupor of established precedent, and superintendents, foremen, and mechanics began to create what may eventually prove to be the foundation for material evolution in machine tool design, construction and operation. While waiting the delivery of tools from the builders, the different shell plants—working on their own initiative and utilizing the material available—began designing and building impromptu attachments for use on the existing equipment to facilitate the production of the shells. These appliances were generally only intended to fill a gap, pending the installation of the standard machinery. The efficient operation of many of these devices, however, was frequently so remarkable that many were retained in service even after the new machinery was installed.

It is due to these crude devices giving such excellent satisfaction that the manufacture of munitions is now universally performed on tools specially designed for specific operations. Production in larger quantities, coupled with standardized product, requiring a relatively high degree of accuracy, resulted in the construction of special single purpose machines, invariably adapted for one particular operation. While many of these special machines could be converted to perform work of a somewhat similar character, the accepted practice is to reserve each individual machine for one operation exclusively.

Revolutionary Changes

Those who have been in close touch with the munitions activity ever since its inception can easily recognize the widely different types of machines that are now employed for the making of shells over those first adapted for this purpose. Two years ago one could visit a shell plant and see there large numbers of standard lathes, many of which were equipped with all the additional attachments and facilities for ordinary commercial operation on variety work. Lathes of various sizes and lengths, those fitted with every modern improvement, such as quick-change gears, screw cutting arrangements, and other accessories which made the machine adaptable for a wide range of work. Many of these tools are still to be found in shell factories but where they are being operated for actual shell production it will be found that many of them have been stripped of such appliances and practically redesigned or remodeled for some specific operation.

However, where plants have been constructed or enlarged during the past two years and new machinery installed for the making of shells, it is seldom that pre-war standard equipment has been acquired—excepting, of course, these machines necessary for tool room work, such lathes always requiring to be of high grade quality. Undoubtedly, a considerable number of standard lathes that have been working on shell production will be utilized for different purposes after the war, but to do so it will be necessary to have the same completely overhauled before the machines can be used for anything like accurate work of a general character.

Effect of Constant Use

The extreme service that shell machinery has been put to, and under the hands of men seldom qualified to operate machinery under normal conditions, has virtually left the bulk of munitions equipment in such a state that the conversion of the same to domestic purposes would be almost impossible. Apart from the rough handling that such tools may have received at the hands of unskilled labor, the nature of the present work is the chief factor effecting the rapid deterioration of this equipment. Under normal peace conditions the range of work performed on machinery in general is of a character that tends to neutralize the wear and tear on the various working parts, as in the majority of metal working establishments the duties required are of a variety to use—almost periodically—all portions of the machine.

Exactly the opposite is the case in shell making practice, where each machine is adapted to one specific detail in the entire sequence of operations. Thus it is obvious, where machines have not been especially designed for some one particular operation, and they are doing this operation for anywhere from one to three years, the abnormal service will eventually, if not already, have practically destroyed the serviceability of the machine for any other duty.

Post-War Possibilities

Four years of war, with its contingent effect upon every branch of engineering and commercial activity, might well, however, give some cause for serious reflection, particularly in relation to the possible development after the war, arising out of the unique experiences of those interested in present abnormal enterprise. Engineering practice, probably more than any other, will be affected by war activities, as production methods have been greatly changed as a result of the knowledge derived by the successful achievement of an enterprise that would have been considered impossible four years ago.

While these revolutionary changes have doubtless been restricted, almost entirely, to developments in design and construction of shell making machinery, it is reasonably safe to predict, or at least anticipate, that post-war conditions will be greatly influenced by what has been learned from the munitions industry. The possibilities of the single purpose machine, as an economic feature of quantity manufacture, has been increasingly emphasized during the past three years, and it may be expected that this class of equipment will be given stil lgreater attention in the future than ever in the past.

However, one of the chief objections to any general adoption of the special or single purpose machinery, is the small number of manufacturing plants using metal working machines, that could apply this method in the production of their product. It will, therefore, be evident that, until quantity manufacture becomes more general, the single purpose machine will not be a serious contender for honors after war, unless some drastic steps are taken towards closer co-ordination of Canadian manufacturers. Nevertheless, the experience gained regarding the possibilities of changes in fundamental design of machine tools, as shown in some of the machines now engaged in shell production, will undoubtedly affect the construction of future tools for different lines of engineering. It is not unlikely that competition will be keener than ever before, the consequence being that the most modern equipment will be essential to economic manufacture.

Current Events in Photograph

THE BAND COMES BACK.

The photo presented herewith is typical of the changed condition of affairs in France. The band, which has been sent to the rear, is marching back through the quiet French villages to once more find its quarters near the front. It is a circumstance that marks the passing of the period of retreat and marks the days of the advance.

Greater Things in This World Than Dollars

A company with a large selling force has one man on its staff in the Eastern section of Canada who does a large business. He makes a lot of money for his firm, and he makes a lot of money for himself. He is regarded as a good business man. But he could do twice as much business if he only knew it.

A few weeks ago he sent in an order to the head office in an Ontario city for two carloads of goods. The price he had quoted was $4.50 per ton higher than the price on the company's accredited sheets for that period. The purchaser had been very keen to get a supply. The salesman was quick to realize this, and took occasion to pick off a few more dollars on the deal. The company could have filled the order at the higher price. It would have made some $400 on the shipment and the salesman would have been credited with that much extra.

The company did not stop to write. It wired first to the consumer stating that the order would be filled at a price $4.50 per ton less than quoted, and the next wire went to the salesman. It is not necessary here to state what that wire announced.

A letter followed stating that the company had one price for its goods. When an increase was made every buyer was notified in advance and no favors were shown.

It's too bad that more people can't get that same system worked in under their skins. There are so many people with a dollar bill or a fifty-cent piece jammed up and glued up against their eye that they can't for the life of them get a proper perspective. If they were permitted to gaze out upon the most wonderful sunset that the hand of the Almighty ever painted they could see nothing but the fifty cents or the dollar that might be gathered in from selling reserved seats to witness the production.

The man who is making his first thousand or his first ten thousand will tell you that grabbing money is the greatest occupation in the world. The man who has grabbed and gathered will tell you that he is just as keen to grab a hundred thousand as he was to grab his first ten.

The man who goes into business with the money-grabbing instinct burned into his brain is going to make a miserable failure in the long run. He may get a reputation for being keen—a few deluded individuals may even regard him as shrewd in his dealings. But allow for all that. What else is he getting out of life? Mighty little. And when he gets to the end of his string he will have the poor satisfaction of looking back over a lot of joyless days, penurious nightmares that he thought once were prosperous days—a trip barren of friendships and a career that will bring few mourners to his day of departure.

Your business career is pretty much like anything else. You will get out of it what you put into it.

Replacement is the Real Cost Price

JOBBING houses in the Dominion are at present in touch with the War Trade Board regarding the price at which their merchandise is being turned over. The steps taken to fix prices here are rather out of the ordinary. Some time ago jobbers were asked to name prices at which sales were being made. The selling price of plate is recognized now at $10 as the minimum. It is worthy of note here that the same material used to be traded around the $2.25 mark in Canada, while in years not far away sales were made in Pittsburg at the figure of $1 per hundred.

At the Canadian mills $7.50 is recognized at Ottawa as the figure accepted and allowed. The War Board is going farther now, and a request has been made of the jobbers that they furnish to the authorities the cost price of the material that is passing from their warehouses. The jobbers, on their part, contend that the government knows the present prices they have to pay, and therefore they know the cost of the material they have in their stores. They take this position because they hold that their costs, past or present, are determined solely by what it would cost them to replace the stock at present prevailing prices.

It looks as though the jobbers were on solid enough ground in taking that position. It is a recognized position. If the government do not accept that ruling they will have to accept the responsibility of guaranteeing to the jobbers that their stock will be replaced at the price at which they paid for it, a thing they cannot do.

As soon as stock, in the form of a security, takes a rise in the market quotations, every share benefits. It is not possible that it could be otherwise. When a slump sets in and values depreciate, every shareholder is poorer in accordance with the amount of his holding. It could not well be otherwise.

When United States placed the price of electrolytic copper at 26c recently, increasing the price from 23½c, all the copper in the country moved up to the new figure. We have not heard of dealers who said they secured theirs at a lower figure, and therefore refused to regard it as being worth 26c. It would cost them 26c to replace their stock. Therefore it was worth 26c to them.

The man who buys the material may not like the idea of having to pay top prices for something the seller purchased in a lower market, but his redress is that he is passing it on into a market that is working at a higher level, and able to absorb the increased price. At any rate it is sound business to put it down as a starter that the worth of any article to you is the price you would be called upon to pay were you going into the market to replace it.

EXPERTS have it all figured out that the Germans may retreat to the Somme. And while we're at it, it will do no harm to recall that back of the Somme there's a bit of a stream called the Rhine.

IT'S quite certain that there's some few people around the office of the Toronto *Globe* who never wandered around a machine shop. An ad in quite conspicuous type, nicely framed, announced that the Dodge Mfg. Co. wanted "Boiling Mill Hands and Laying Hands." The "Boiling" part of it may have had something to do with the 102-degree weather, but we can't tumble to the "laying" hands, knowing that the Dodge people have no poultry yard. "Boiling" and "laying" is a fairly long way from "boring" and "lathe."

"DOES IT PAY?" NOT ALWAYS BIG CONSIDERATION

J. S. Woodhouse Started Work at $1 Per Week 19 Years Ago—Now General Superintendent Over 1,200 Workers in the Same Shop

LIKE most men who have got to the top, or near it, J. S. Woodhouse was reluctant to be interviewed for publication. In fact, his consent was not won until it was made plain that the purpose of the interview was to enable CANADIAN MACHINERY to dispense encouragement, especially to all younger men in Canadian machine shops who are workers by day and students by night. Even then he requested:

"Just give the bare facts.'

All of which goes to show that the self-made man without exception has a soft place in his heart for the younger chap whose aim nears the perpendicular.

J. S. WOODHOUSE

Although born in the town of Lindsay, Ontario, 34 years ago, Mr. Woodhouse has been a resident of Toronto for almost as long as he can remember. He is of English parentage on his mother's side, of French on his father's.

When only 15 he dropped public school books for the more formidable text books of the machinists' craft, and entered the employ of Mr. W. H. Banfield. Except Old Country trained machinists probably few men in Canada experienced work at pay as lean as his in those early years.

"I started at a dollar a week," Mr. Woodhouse said. "And I was given an increase of fifty cents each six months until I was making four dollars weekly."

"But you realized your pay wasn't altogether in the coin of the realm," CANADIAN MACHINERY suggested.

"Yes, I suppose I must have," Mr. Woodhouse admitted. "I recall one offer I had that nearly staggered me. It was made by a shop across the street. Thirteen dollars a week, I think it was. Three times as much as I was making, but I didn't take it."

At the age of 24, after nine years of combined work and study, the latter frequently extending far into the night, Mr. Woodhouse accepted a position with the Ontario Metal Stamping Co., of Toronto. In making the change his object was to acquire experience in American manufacturing practice. Four years later, his object attained, he returned to W. H. Banfield & Sons, Limited, as superintendent of manufacturing. Soon after he was promoted to the position of general superintendent.

It might be said that the Banfield plant has been his university. The first rudiments of machine shop practice to the fine art of die and tool making he learned in it. He worked his way from the bottom to the foremanship of each department as he climbed.

Asked whether the young men among the 1,200 employees now engaged at Banfield's had it in them to achieve an equal success ,Mr. Woodhouse said:

"Seventy-five per cent. of them, yes. And in a given time young machinists can go farther to-day than ever before. But I wouldn't say they would all be willing to work as hard as I have to get ahead."

On the termination of munitions contracts, Mr. Woodhouse expressed the hope that he would be able to retain all his better machinists. "If I can't keep them on without their losing any time," he said, "I hope to soon work them in on our regular lines of machinery, dies, tools, power presses, sheet metal stampings and brass goods. We may carry on in an enlarged way," he intimated.

Mr. Woodhouse married Miss Jennie Hyndman, of Toronto, in 1908. He is father of two little girls and one boy that do him credit.

Ever at One of These Things?

When church collections take a slump, when coin comes slow and tardy, the remedy they all apply is to hold a garden party—sometimes it is a Sunday School, and then again a league, that's sufferin' from hot weather cramps and all-around fatigue.

So the garden party's dusted off and listed up to view, and advertised as something fierce, astonishing and new.

The minor members of the flock are gathered in a row, and sent to peddle tickets for to go unto the show.

They pester folks to spend a dime, they claim the cause is just—if you don't buy up goes the snout in horrified disgust.

You plant your ticket at the gate, you pass within the coop, expectin' that you'll get a feed of pork chops, hash and soup.

An orchestra is on the job, it sits beneath a shrub, and vendors hang around to sell their garden party grub—you wander round the premises to see what you can see—and squint a Chinese lantern what's pasted on a tree.

You eat ice cream from out a dish, you gobble from a cone, until you've got but 30c from out a hard-earned bone.

And perhaps they've got a programme on, you flop your ears and listen, a speaker says the folks at home don't know just what they're missin'. And sure, by heck, you'll wander to the place, the candy booth, and chuck their home-made pillets into your hollow tooth.

The orchestra it plays a jig, but of course you musn't dance, though all the church folks surely would if given half a chance.

When quittin' time has wafted round, and they've sprung the last events, they call for every husky man to pack up booth and tents. You lift a plank, you hoist a box, you cant a pile of dishes, and kick the proppin's from the place they had their sawdust fishes.

And then you croak in voice profound, backed up with handshake hearty, "I do enjoy, by jing I do, a bang-up garden party."—ARK.

ST. LOUIS *Globe-Democrat.*—Sign in a Tonopah restaurant: "Use only one lump of sugar in your coffee. Stir like hell, for we don't mind the noise."

MARKET DEVELOPMENTS

The Fixing of Prices is Not Settled Matter

War Board Want Cost Prices From Jobbers—Latter Hold That Replacement Values Are Cost Prices—Production is Keeping Up Well in Connection With Work at Big Producing Points

THE production of steel mills in United States has a very pointed meaning for Canadians at present, more so than ever before. In the matter of allotments Canada is treated as a section of United States, and the higher the production figures the greater the quantity of material for this country. Pittsburg reports that the furnaces in that district have given a good performance during the hot weather. The falling off has been less by a good deal than is usually the case, and the men have stayed with the job remarkably well during the heated term.

Price fixing has not been altogether accomplished in Canada, although steps are still being taken to reach this end. Some time ago the War Board at Ottawa requested jobbers to give the price at which sales from warehouses were being made. This was done, and at the same time a move was made to fix a price at the Canadian mills, which, in the case of plate ran about $7.50 f.o.b. factory. The selling maximum was $10. The next step is that the jbbbers are requested to show the cost of the material now selling from their warehouses, which may have been there for some time. The jobbers are not so ready to do this. Their position is that the material they have on hand is worth what it would cost to replace it at current prices. They claim that the government is in possession of this information, and therefore in a position to know the cost of their material. The matter has not been adjusted.

Canadian dealers are having no easy time trying to enter the U.S. market for steel material in any form. It is impossible to get any promises of definite shipment. The first half of 1919 is about as close as any of the U.S. mills care to come to date of probable shipment.

The scrap situation is bad at U.S. points, and for the present it looks as though Canada were a little better off than the States. There are a number of foundries in Canada, though, that would like very much to secure an adequate supply of good machinery scrap, or anything that might be high in silicon.

There is a keen demand for supplies for shops machining shells. Some of the forgings used lately have been rather difficult in cutting, and consequently harder on the tools employed. In this connection men who have worked at shells for some years now claim that the forgings made in Canadian shops are more uniform and easier to work than any they have encountered. In fact the size of production figures and the smallness of rejections all indicate that Canadians have reached a high stage of efficiency in the manufacture of projectiles of all sorts.

COOL WEATHER IMPROVES OUTPUT BUT STEEL MARKET STILL ACUTE

Special to CANADIAN MACHINERY

MONTREAL, Que., Aug. 20, 1918.—General industrial conditions are now taking on a more settled appearance, due no doubt to the closing of the holiday season. The cool weather has also been an influencing factor in plant operation, and production figures for the past week have shown a material increase. This condition is very encouraging but business is still hampered by the inability to obtain the necessary supplies for maximum operations. Shipments of steel plates are still backward and the situation in this respect has taken on a more acute stage The old metal market has been fairly active particularly in heavy melting materials. The metals are steady without feature.

Steel Harder to Obtain

The steel situation in general is one that shows little improvement over that of the past few weeks. The regulations regarding the distribution of material are very often a puzzle to the consumer as even those in the preferred class have considerable difficulty in securing material from the mills. It frequently happens that a consumer may be given to understand that his requirements will receive prompt, or at least early attention, but when the orders are placed in the hands of the producers they are invariably advised that the quantity of orders now on the books makes it impossible to state a definite date for delivery. The filled up condition of the mills and the uncertainty of government requirements is the chief argument against early delivery. The local situation is unchanged and dealers report a relatively quiet market with quotations firm.

Steady Demand for Metals

No features of special interest have developed during the week and the market is steady in character with all quotations firm and unchanged. Dealers report a steady demand for electrolytic copper but supplies are often hard to obtain. The tin situation is still uncertain but sufficient metal is coming through to satisfy essential requirements. Other metals are comparatively quiet but the demand is quite steady. No price changes are reported.

Heavy Tool Demand Quieter

Business in the machine tool trade is quieter, the demand for the heavier tools showing a falling off. Some activity has been reported in second hand equipment, particularly in connection with tools suitable for tool room work. All supplies are very active, notably chucks, drills, cutters, etc. In general the prices are well maintained, dealers reporting a steady market.

Good Business in Steel Scrap

Apart from a steady demand for steel scrap for shell making purposes, the situation is devoid of special interest. Some foundries are having difficulty in getting sufficent steel scrap for their requirements. Some little trading has been done in machine cast scrap, but the supply of this material is almost exhausted and grey iron foundries are forced to use more pig for their operations. Local business is quiet and price quotations are firm.

DON'T LIKE METHOD OF FIXING PRICES

Dealers Claim Replacement of Material Is the Price of Present Stock

THE sale of machine tools goes in starts and pauses at present, and this week comes into the category of pauses. Shops taking on new business for the making of shells have been pretty well cared for, and if the machinery is not actually in the premises the work is well under way.

Contractors in this district continue to get good results from their shell plants. The mechanics and workers are better acquainted with the various operations now, and there is not the same period of experiment to pass through now with its delays and losses. Forgings furnished from Canadian plants are in good shape when the mills get them.

The demand for supplies is brisk, both for carbon and high speed. No new lists are out this week, and prices have remained unchanged and firm.

The Matter of Prices

The authorities at Ottawa are proceeding with their task of trying to fix prices in the Canadian steel market, but they are running into some obstacles. Critics of the way in which they are doing business are firm in the opinion that they should have definitely arrived at a fair cost before they began to set in motion machinery for fixing the prices.

Some time ago the jobbers were notified that in future they would be required to state the price at which goods leaving their warehouses were charged to the purchasers. This was complied with in most cases by the jobbers. Orders that neglected this detail were promptly returned. It is also understood that the Government at the same time took up the matter with the mills.

The latest move is that the jobbers have been requested by the authorities to state the cost price of the material in their warehouses as it is sold. This the dealers are not showing any great desire to do. In fact it is understood that several of the jobbers have sent word back to Ottawa that they see no reason for this. Their position, in brief, is that they regard their cost to be what it would need to replace the stock. In fact they hold that the replacement idea is one that is pursued and recognized in all lines of business, and they see no reason why there should be an exception made in the present case. Hence they hold that the Government from present prices will know the cost, figuring the same from the replacement price. Whether the Ottawa authorities can be brought to see things this way remains to be seen.

POINTS IN WEEK'S MARKETING NOTES

There is an unending demand for steel plates. Everything has to stand aside while material is flattened out for this work.

—

The summer curtailment of steel output is distinctly less than usual.

—

War orders that can use discard steel makes the showing of production much better.

—

The scrap situation is bad at U.S. points and its is rapidly growing worse.

—

Good results are being obtained at the shell plants in this district. This is due to better acquaintance with the work and the elimination of early mistakes and experiments.

—

Fixing prices is not proceeding smoothly in Canada. Jobbers hold that the price of material they have in stock is the figure it would take to replace the material at present prices.

—

Shipments of steel are not being promised by American dealers on definite dates. The nearest approach is "some time" in the first half of 1919.

—

There is practically no pig iron at all for users who have not a particularly strong claim regarding priority work.

—

In sheets and merchant bars, according to Pittsburg advices, the distribution to jobbers will be very light.

—

A plant which United States is building in France for relining guns will call for an investment of $15,000,000.

Shipments Are Indefinite

Deliveries are none too good just now. There is a tremendous demand for plate. In fact it seems that everything in the line of steel must be rolled into plate to conform with the enormous demand for this material in ship yards and hoiler shops. There is some interest in the demand for plate for boilers to heat the Ottawa Parliament Buildings. There is some division of opinion as to whether it is of the most essential sort or not. Some dealers are quite open in declaring that there are greater things under way now than the heating of the Parliament Buildings at Ottawa, holding that the business of the country has been carried along so far and that the same thing can probably be said of the future.

But apart from that Canadian consumers are not getting very much encouragement from Washington. In fact one letter came back to-day from a large producing company in the United States stating in reply to a query about delivery that it "might" be made in the first half of 1919. But it is not possible to hold any United States company to definite promise in the matter of delivery. They prefer to abide by the wish of the Government that they shall place their whole stock at the disposal of the Government for war purposes, and are taking the allocations of the Washington authorities as final.

Prices are holding this week at the quotations of last. No further advance is made on the lists over $8.25 for galvanized sheets, although some of the jobbers are working around the $8.50 price. Some time ago sheets for use or for galvanizing were coming into this country very freely. In fact it seemed for the time being that the embargo had simply been shot to pieces. When this condition arrived there was some of the pre-war rivalry for business, and prices came down just like they used to do. This was all very well until the report came that the shipments from the United States would be severely curtailed. Then it was that the stiffer price came. The tendency is still up.

Little Scrap Moving

There is not a great volume of business passing in the scrap yards this week, and price changes are few. A small gain is made in crucible copper and stove plate sells one dollar a ton up at $20. Makers of stove plate are actively in the market for supplies, but are not securing them in large quantities. They prefer a good line of machinery scrap, but a good many other concerns prefer the same thing just now, and there's not enough for all. In fact high silicon scrap or pig is wanted. A large radius is being covered at present in the search for all available scrap that can be located at marketable points. Some that is unearthed is at points so far from shipping facilities of easy access that it is hardly commercially possible for present use.

No Outstanding Orders

Machinery and machine tool dealers, as well as those handling supplies report fair business, especially the latter. Some of the shells that have been forged in the United States have been much harder than the ones made in Canada. They are harder to work, and hence harder on machine tools, especially high speed. Demand is good for high speed lines, and stocks are rather depleted at some points. In fact there is some Montreal business being handled right now in Toronto because of this fact. The lists that have been used as the basis for some time are till regarded as correct, and no immediate changes are in sight.

Prices Stand Here

No changes are noted in the market prices for non-ferrous metals. Despite the scarcity of tin, a certain amount of it arrives in the local market at intervals, of course all coming through the English ports. Price advances do not retard the amount of business being handled. One dealer in a large way stated to CANADIAN MACHINERY this morning that in the case of copper this tendency had been noted recently. The United States Government raised the price. The dealers raised their price to the new figure. The trade paid it and passed it along, until it reached the last man to buy, and he paid the thing and absorbed it. The amount of business was just the same at the higher price as at the lower.

U.S. TO BUILD PLANT IN FRANCE TO FIX GUNS

Large Outlay to Be Made for the Work in Connection With Relining

Special to CANADIAN MACHINERY

NEW YORK, August 22.—Government purcrases of machinery of various kinds continue to monopolize the attention of manufacturers and dealers in all sections of the country. It is estimated that the business now being placed and pending calls for the expenditure of $30,000,000; half of this sum is required for the tools to be installed in the gun relining plant that the United States Government is building in France.

The cost of its construction will be about $30,000,000. Notice of this project was first given by CANADIAN MACHINERY several months ago. In the last week, the Chief of Ordnance of the War Department announced the completion of plans for this great plant. Large orders have already been placed for rifling machines, for gun-boring and engine lathes and for grinders. Locomotive shops that are also being built in France by the United States Government are being equipped with tools made at home. The Director of Military Purchases for Railways is now buying many cranes for these shops and is also buying $1,000,000 worth of tools.

More New Business

The War and Navy Departments continue to give out new contracts for guns and shells, most of which are going to manufacturers in the Central West, but some orders in the past week have bene placed with Eastern shops and notwithstanding the Government orders creating a barred zone in the East, in some cases Washington authorities are giving permits to extend manufacturing plants working on Government contracts. The Ordnance Engineering Co., New York, which is to manufacture a new type of star shell, has bought automatic screw machines and other equipment for this purpose.

The American Radiator Co. has received a contract for 4.7-inch and 155 mm. gas shells which it will manufacture at its Buffalo plant. For its gun plant at Bayonne, N.J., the same company has bought a large number of tools to increase output of naval guns. The Batavia Steel Products Co. is producing 75 mm. shells and the J. J. Carrick Incp., an affiliated concern, is making 155 mm. shells at its Buffalo plant. The shell making equipment for these two works have been bought in Canada. In this connection, it is interesting to note that the Leaside Munition Co., Toronto, Ont., which recently received a contract for 12-inch shells from the United States Government, is spending $3,000,000 for an addition to its plant to execute the United States order. The shells will be forged and machined.

Other Large Orders

Several large companies in the Chicago district, it is reported here, are negotiating with the Government for the manufacture of 155 mm. guns and projectiles. The Crocker-Wheeler Co., Ampere, N.J., manufacturers of motors, generators, and other electrical equipment, is now utilizing 75 per cent. of its capacity for making radio equipment and other electrical apparatus for the United States Government. Work is being rushed, the plant operating a twenty-four hour schedule.

Besides the Wright-Martin Aircraft Corporation and the Pierce-Arrow Motor Car Co., manufacturers of automobiles are turning to the production of air motors and aircraft accessories. The Locomobile Co. of America, Bridgeport, Conn., is building a new shop for the manufacture of motors to equip armored tanks. The H. H. Franklin Manufactur-

PRODUCTION OF PIG IRON RESTS ON INCREASING OUTPUT OF U.S. COKE

ONE of the biggest questions that is now facing United States is the increasing of the supply of pig iron. Behind this, of course, is the matter of securing enough coke to do it with, and back of coke lies the matter of increasing the mined quantities of coal. There is no use talking of increasing plant capacity even for war work until these matters are first attended to, because the limit to everything is the limit of the furnaces. The supply allotted to Canada will not increase until the total output is increased at production points across the line.

Reports concerning the situation in United States for the present week are as follows:—

Cleveland.—Heavy demands still continue to be made for iron allotments here. Foundry men are figuring heavily in these requests. There is an uncertainty which is becoming quite marked in regard to supplies for the future, owing to a number of the furnaces changing over to basic, and the claim is made that some of the essential contracts will be held up by this reason. A delegation of foundrymen will lay the matter before Washington, and ask for some change in the regulations, or as an alternative put it up to the government authorities to allocate to them enough iron to keep up with their work.

Boston.—Some of the foundrymen report liberal deliveries of coke, but the same cannot be said in regard to iron, There has been no time in the past two years when any of the foundries in this district had an oversupply of iron.

New York.—There is a large amount of trade moving, but it is strictly of the immediate need variety. Very little business is booked for first half delivery in 1919, and even these orders are made conditional upon the needs of the government, which sees to it that every order let out is tied up good and tight to the war game.

Philadelphia.—Reports here indicate that some 1919 business has been booked, on the basis of furnaces taking care of old customers. Only a few of the Pennsylvania furnaces participated in the business.

Pittsburgh.—The hot weather that has now run into quite a stretch has succeeded in "getting" some of the furnaces, and figures will show that there has been a dropping off at some of these that will run from 30 to 40 tons per day—not much in one place, but when it is kept up many days at many places the aggregate will be considerable. August figures, from this prediction, are likely to show a rather sharp decline. Reports coming in from some of the centres in this district state that the supply of coke is such that it is actually curtailing operations.

Buffalo.—Inquiries for pig iron around here are so heavy that it is quite certain that nothing much will be exported from here for some time to come. Very few contracts are being made, as there is a tendency to let the government officials look after the allocating of the furnace output.

Youngstown.—It is reported that some finishing mills here are down this week because there is not sufficient bessemer capacity to supply them with bars. The shortage of pig iron is affecting a number of the plants here.

Chicago.—If an old customer is known and can certify that he has government business well into 1919 that will guarantee his consideration in the pig iron market and there is some chance of him being entertained by the furnace agents. Otherwise he can get no definite promises. In fact the taking of contracts is being discouraged until the situation becomes very much clearer.

Cincinnati.—Encouraging reports continue to come in regarding the manner in which the men have stuck to their work during the hot weather, and in consequence production has suffered little here. Basic and malleable makers receive close direction as to the distribution of their output among the melters on government work.

ing Co., Syracuse, is buying additional equipment for the manufacture of crank shafts for Rolls Royce airplane motors. The Willys-Overland Co., Toledo, is also preparing to add to its motor-making equipment. These purchases have naturally followed the advice from Washington that automobile manufacturers should utilize 100 per cent. of their capacity for war work, thus eliminating the manufacture of pleasure automobiles entirely.

Activity continues among manufacturers of cranes. The largest list for cranes put out in the past week came from the Air Nitrates Corp., New York, which is building two plants, one at Toledo and the other at Elizabethtown, Ohio, for the manufacture of nitrogen by atmospheric fixation. Specifications for 18 cranes have been put out. The Thompson-Starritt Co. has purchased 89 chain hoists through J. N. Kinney, New York City, to be installed in the Government powder plant at Charlestown, West Va.

THE SCRAP SITUATION IS BAD AND GRADUALLY GROWING WORSE

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Aug. 22—Production of steel ingots in July was at the rate of about 42,250,000 gross tons a year representing a decrease of almost 3 per cent. from the June rate. This was the first decrease since January and it was a much smaller decrease than usually occurs in July. The first fortnight of August witnessed exceptionally hot weather, and this month's output is likely to show a further decrease, but on the whole the steel trade is well satisfied, the summer curtailment being distinctly less than usual.

A little information leaked out recently which indicates that the proportion of finished roled steel to ingot production is running a trifle higher than normal, this being doubtless due to the small scrap loss involved in rolling shell steel. Earlier in the history of shell steel manufacture there were particularly heavy scrap losses, but the scrap losses are now less than is the case in the rolling of the average finished steel product, due to greater skill in manufacture, to the fact that shell steel is running much more to large sizes than was the case in 1915, and to the efficient manner in which the War Industries Board has picked out war orders that could well be filled by using discard steel. As details of the various articles and implements that are used in the war are not given out it is impossible to particularize as to what is being rolled for war purposes from shell discard steel.

Using the proportion indicated, it appears that when the steel industry is making ingots at the rate of 43,000,000 gross tons a year it will be making finished rolled steel at the rate of about 38,000,000 net tons a year. It is regarded as conservative to estimate the ingot output in the present half year as at this rate, for while July and August fall slightly behind this should easily be made up when cooler weather arrives. Thus there is a reasonable expectation that 18,000,000 net tons will be made in the half year, this comparing with the observation made a few weeks ago by the War Industries Board that the production of more than about 16,500,000 tons could not be counted upon. The board was estimating the requirements at 20,000,000 or 21,000,000 tons, and later in a statement to the Fuel Administration, calling for a full supply of coal for the steel industry it put the requirements at 22,000,000 tons.

The Shortage of Scrap

It is true that 43,000,000 tons of ingots does not represent the capacity of the industry, as computed for normal times, but rather about 90 per cent. of the capacity. On account of various difficulties, however, easily the chief being the shortage of scrap, the steel making facilities cannot produce their normal tonnage. The scrap situation is bad and growing worse. The shortage, of course, is due to the peculiar nature of the industrial and other operations now being carried on, which are such as to bring out very much less than in normal times. The railroads are wrecking very little rolling stock, scarcely any bridges or buildings are being torn down and there is little new scrap being made. Even the shell factories are producing much less scrap than formerly because they are making shells in a different manner.

An important meeting is being held in Washington this week between J. Leonard Replogle, Director of Steel Supply, and the special sub-committee of the American Iron and Steel Institute, composed of Messrs. Gary, Farrell, Dinkey, Topping, Clarke and Grace. All that is given out definitely is that the meeting is a very important one and has to do with steel supply. The inference is that it has to do with the project, discussed at some length in this report of a week ago, of increasing the output of steel by new construction. What would be required would be additional blast furnaces and open-hearth stel furnaces, as enough coke and ore could probably be provided, also enough steel rolling and finishing capacity. With supplies of material, labor and transportation facilities limited by the heavy demands in so many directions, the question is whether such new construction would be advantageous.

Freight Movement

The monthly report of ton-mileage on the railroads for May does not make a favorable showing, comparing the figures for May with those for the preceding month or with those for May, 1917. Part, but perhaps all, of the deficiency is due to the adoption May 1, 1918, of the universal interline waybill, whereby more freight than formerly that started on its journey in May did not get into the statistics, but will lap over into June. The figures indicate that last May freight was moved at the rate of 418,000,000,000 ton-miles a year, against rates of 448,000,000,000 in April and 439,000,000,000 in May, 1917. Apart from the disturbance caused by the new waybill, other items in the monthly statistics seem to suggest that the railroads did not improve their service in May. In the fiscal year 1913, the best year before the war, the ton-mileage was only 301,398,752,108, so that on the whole the railroads have been doing extremely well, except in December, January and February.

Scarcity of Pig Iron

It appears that every ton of pig iron produced must be made to do its full duty in serving the more essential industries, and allocations in favor of plants engaged in the most important work are so heavy and so hard to meet that there is practically no iron for consumers who do not have a particularly strong claim upon it. Allocations since May 1, for the industry as a whole, total about three-quarters of a million tons. This figure becomes more impressive when it is noted that the total production of pig iron by merchant furnaces is only about 900,000 tons a month, the remaining output being by steel works whose iron is rarely if ever touched by allocations since they already use using it in war work, and when it is noted further that the merchant furnaces are all working under the preference schedule, which would in general make the iron go to the right place without allocations. Thus between 20 and 25 per cent. of the make has been allocated when the furnaces were already filled with orders and were endeavoring to distribute their output to the best advantage according to the standing their various customers had on the preference list.

Steel Products

The great majority of steel consumers are receiving fairly good deliveries of finished steel products, because they have converted their operations into war work. Those whose operations entitle them to no preference are receiving scarcely anything. They are given the consolation that they should seek war orders. That would entitle them to steel if there were any, but it would not automatically increase the supply from which the steel shipments would have to be drawn.

The pipe mills expect to make a fairly good distribution to jobbers under the instructions issued last month, and the distribution of wire products will be fair. In sheets and merchant bars the distribution to jobbers will be very light.

Tin plate production in July was over 3,100,000 base boxes, easily a record for July, when there is usually a sharp curtailment in output on account of the heat. Production in the first six months of the year was about 17,250,000 boxes.

THE COAL SITUATION IS STILL A VERY SERIOUS ONE IN THIS COUNTRY

Special to CANADIAN MACHINERY

SYDNEY, N.S., August 22. — The workmen of the Dominion Iron & Steel Company in Sydney have for a third occasion absented themselves from work on Sunday, and as a result the operation of the plant has been hindered during the current week and its production much lessened. No action has yet been taken by the government in the matter, although it is understood that Senator Robertson and A. K. MacLean are being despatched from Ottawa to look into the situation. It is believed that a more serious state of affairs is impending, and the apparent inaction of the government is giving rise to unfavorable local comment.

The wage adjustment between the A. M. W. and the Dominion Coal Company affecting both the Glace Bay and the Springhill Collieries has been satisfactorily agreed upon between the parties. The wage contract between the coal companies and the A. M. W. of Nova Scotia expires at the end of 1918, and it is expected that negotiations looking towards a new arrangement will shortly be commenced.

Will Make Coke

The first block of the new coke ovens built for the Dominion Iron & Steel Company at Sydney are now being heated preparatory to commencing coking operations, and it is expected that coke will be made within the next few weeks. The second block of ovens will be a month later in commencing to make coke. The installation of a light oils recovery plant is also being undertaken. Work is proceeding on the installation of a new Baum washer. This type of washer is designed to give a washed coal very free from excess moisture. The new coke ovens are the most modern type, and have an extremely rapid coking capacity. The reconstructed No. 1 blast furnace is also practically ready for operation. The combination of a washed coal free from excess moisture, the new coke-oven plant, and the re-constructed blast furnace is expected to ensure a regularity of operation that will result in a much larger yield of steel of uniformly good quality.

To Increase Production

It is anticipated that within a few weeks the plant will be producing up to 36,000 tons of ingot steel per month, and that greater tonnage records will be obtained than previously in the history of the steel plant. It is therefore to be hoped that labor disputes will not interfere with the consummation of a policy that has entailed the expenditure of large sums of money on capital extensions and repairs. It may be noted that these expenditures have been made out of revenues, and that so far the shareholders of the steel company have not benefited by any increase in the dividend payments. At the same time the increases in wages to the employees have totaled from 70 to 100 per cent.

Reliable Confirmation

An authoritative confirmation of the statements made in this letter regarding the coal situation has been issued by the President of the United States, who makes the pregnant announcement that the danger arising from the scarcity of coal "is the most serious which confronts us." The statement could scarcely be graver in its import, or more comprehensive, and we have not been accustomed to regard the President as given to overstatement. It is surprising when such eminent leaders as Lloyd George and President Wilson express themselves so definitely in regard to the importance of coal supply that the action of the Allied governments should have been so indefinite and purposeless in so far as the production of coal is concerned. There has been an entire misconception of the problem, as the very title given to the fuel controller discloses when the purport of that title is analysed. In considering the problems of fuel distribution and the controlling of fuel prices the public and the officials of the government charged with these duties have overlooked the main problem, namely the question of production.

A Great Big Problem

In modern warfare coal is the beginning of all things. The authorities have looked upon coal supply with the eyes of civilians; they have failed to comprehend its prime military importance. They have confused coal mining with other commercial industries. In our letter of the 4th July we stated that "to those who know the situation, the problem of coal production is not the least among the problems that face the allied leaders. If the coal production declines to a point where it restricts the output of munitions and the transport of troops, the gravity of the situation will appear in its true light, and things are approaching such a point." President Wilson now says: "Without an adequate supply of coal our war programme will be retarded; the effectiveness of our fighting forces in France will be lessened, the lives of our soldiers will be unnecessarily endangered and their hardships increased, and there will be much suffering in many homes throughout the country during the coming winter." The writer ventured to predict that the grim actualities of war will compel that the needs of the army and navy shall come before the requirements of the people at home, and that if these activities were threatened the people at home would have to freeze. President Wilson does not say exactly this, but it is what he desires should be inferred from his words.

An Essential Industry

The authorities should cease to concern themselves with the questions of price fixing, with the supposedly high wages earned by the miners, and other secondary questions, and should approach the problem from the standpoint of increasing by every possible means the production of the most important munition of war, that munition which is the genesis of all others, and failing which, every wheel of the machinery of war and industry stops. Coal is basic, primal, fundamental. It is like the ignition spark to the gasoline engine. Without it the machinery is dead.

President Wilson is once more to be congratulated inasmuch as he has made clear to the allies, in a few pregnant sentences, that which others have been preaching in season and out of season for the past four years. He has removed the mask of misrepresentation, misunderstanding, ignorance and bias that has surrounded the matter of the coal supply, and when he announces that the danger arising from the present coal scarcity "is the most serious which confronts us," he states the exact precise truth. It is to be hoped that his diagnosis of the problem will be followed by the application of proper remedies, at least so far as Canada is concerned.

NOT ENOUGH SCRAP MATERIAL COMING TO SATISFY DEMAND MADE FOR IT

Pittsburg—Heavy melting steel guaranteed low phosphorus scrap and heavy shell turnings are in especially strong demand here. Railroads are assisting as best they can in the search for scrap and will aid in the movement of securing it by having cars in readiness for quick shipment. Although good tonnages have been secured in this way they have not been of sufficient size to make any great impression on the market.

Chicago—Scrap dealers here report that their books are still filled with orders that have been taken some months ago. In fact they have more contracts on hand than there is any chance of their catching up with. Cast scrap is in great demand and the supply is small, while re-rolling rails are practically unobtainable and such tonnages as appear in frequently are placed immediately.

New York—The somewhat cooler weather that has been prevailing the last few days has enabled the scrap yards to work at greater speed than for some time past. Even allowing for this though, the turnover in the yards is not near the capacity of former years.

Buffalo—There are no indications here of the demand for scrap metals letting up. The demand is not confined to any one particular line, but it may be quite correctly stated that the buyers are in the market for everything that the dealer has. Cast scrap is in a very strong position just now, along with every heavy grade. Buyers from other districts that usually do not come here for supplies are reaching out into the Buffalo market, but the car shortage does ont give them much encouragement of success.

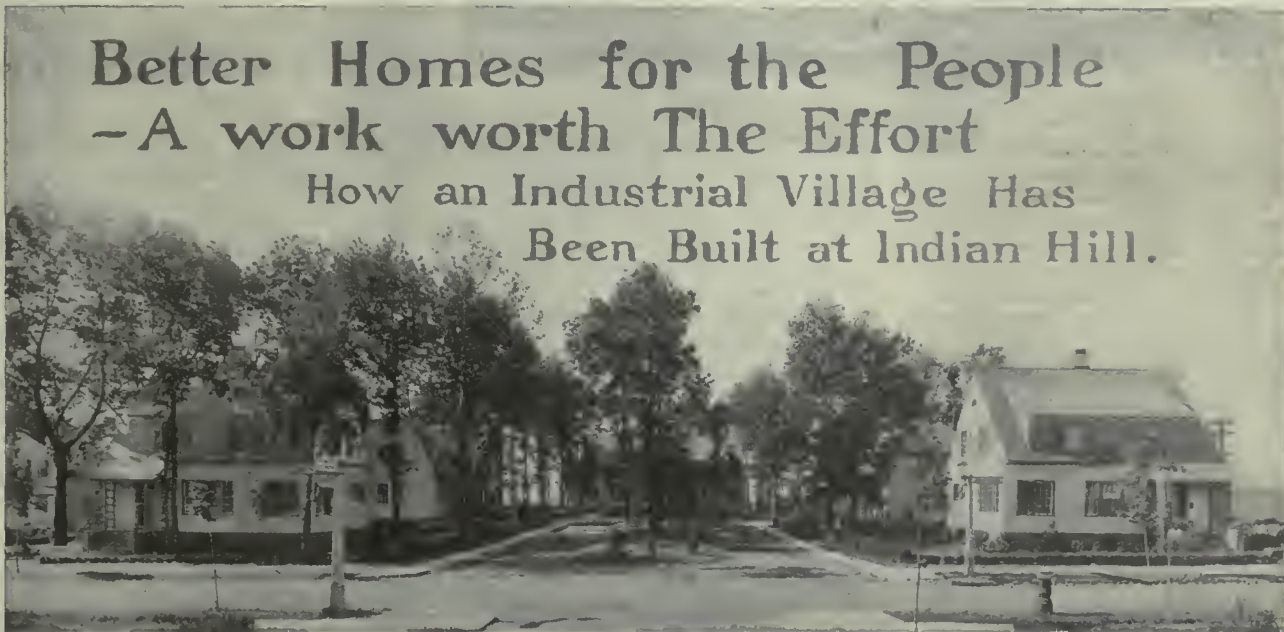
Volume XX. No. 8. August 29, 1918.



By Charles C. May

DESCRIPTION of the settlement which the Norton Company of Worcester, Mass., is building for its employees might well take for its text, "A city that is set on a hill cannot be hid." Certain it is that if the development is successful, its attractions will become a beacon to the countryside for miles around; if it should fail in any considerable degree its shortcomings will become a lesson that he may read who runs anywhere in the vicinity.

This means that Indian Hill is the possessor of a most commanding site. Removed by several miles from the heart of the city of Worcester, lies Indian Lake, a sheet of water of perhaps a mile and a half in length by half as much in width. Its banks have not, as yet, been reached by indstrial development and lie happily unspoiled—a challenge to the city of Worcester for appreciation and preservation.

Indian Hill itself—the "thirty acre tract," as it has been named during the development—occupies the lofty ridge that thrusts its point out toward the head of the lake. Before it lies the open country in opulent variety in all directions, to the limits of perhaps 300 degrees of the circle. Holding the northern end of the lake, the major part of the hillside slopes toward the south, with the higher wooded areas at its back for buffers against the north winds. This is a detail of not merely sentimental value, for in these latitudes the land of extended outlook is also the land of bitter-cold blasts.

ILLUSTRATION SHOWS ELEVATION OF HOUSE OF TYPE N2.

Back from the north-eastern corner of the lake and within the angle between the main railroad and its branch lies the plant of the Norton Company. Primarily for the adequate housing of these men and their families was formed the Indian Hill Company, a subsidiary of the Norton Company, entitled under the Massachusetts laws to acquire, develop, and dispose of real estate. It is accordingly the Indian Hill Company which has brought together and is now engaged in developing holdings of some 116 acres, of which Indian Hill proper forms the first demonstration. The development, we have said, is primarily to provide adequate housing for its employees, with a view toward individual ownership, permanency

GROUP OF HOUSES, INDIAN HILL DEVELOPMENT.

and contentment in employment, and resultant general efficiency. In these objects the company is self-seeking only in the same degree that the word might be applied to those others of its institutions for the office workers—the auditorium, the gymnasium, the rest-periods, the hospital, the tennis courts, to name some of them at random.

Secondarily, and in no sense selfish, was the company's hope that in wrestling with their own housing problem they might at the same time make some contribution toward the solution of the wider problem of workingmen's houses in general and toward the suppression of that pest of Massachusetts—the wooden three-decker. It is an outcome devoutly to be wished.

One cannot be too thankful that Indian Hill did not belong to one of those communities where the ruling of a standardized street system reigned supreme. Had it been so their engineers would have done exactly what New York's did to Manhattan Island—they would have laid down on the map of Indian Hill a gridiron of rectangular streets that had no respect for height nor depth, that recognized no main artery where traffic would naturally congregate, that had no eye for a magnificent view, that could afford no resting point with an outlook toward the sunset. Is it inconceivable that anything so inflexible and utterly devoid of imagination could happen to a spot like Indian Hill? Yet, remember that in 1807, when New York's plan was concocted, the Island of Manhattan above Chatham Square lay as virginal and as unstandardized as is Indian Hill to-day.

The Community Plan

The plan that has actually been worked out by Grosvener Atterbury of New York, town planner for the development and architect for the houses, is the result of careful study of all the conditions. It seeks to secure the best possible grades for the main circulation roads, and only slightly steeper for the minor, non-traffic ones; it shows deference for the natural features of the site in conformation woodlands, view and exposures; it seeks to provide quiet bypaths away from the lines which will one day be thronged with streams of traffic, in order that in these spots may always be preserved that domesticity, intimacy, and hint of aloofness that belongs rightly to cottage surroundings.

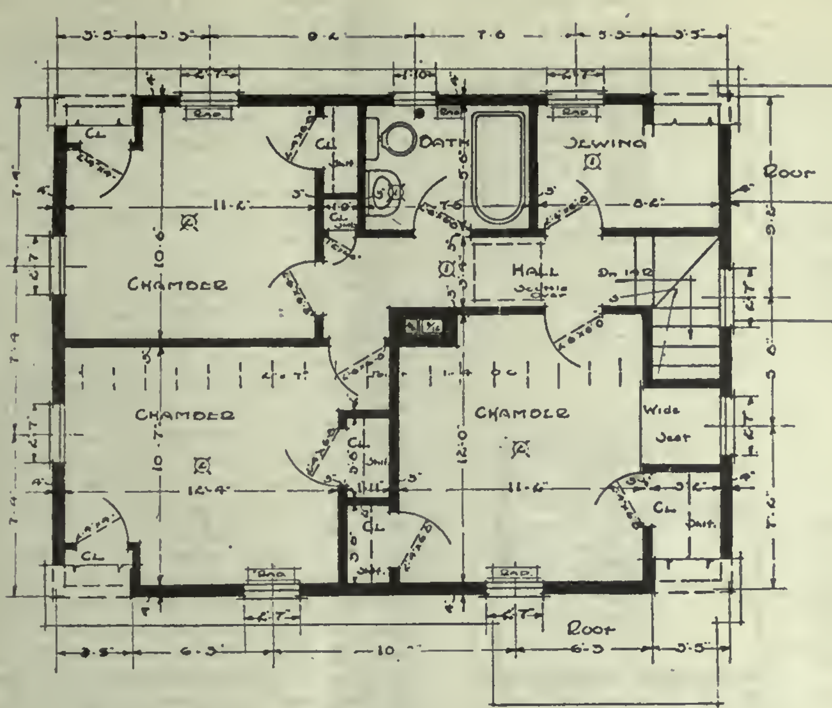
The main lines for traffic, as projected, are Indian Hill road and the street that climbs up the shoulder of the hill after crossing the railway cut and circling in a double sweep to enter the Community Center from either side. This latter approach anticipates the creation of a shore drive which, it is to be hoped, will some day skirt the edge of the lake, where it would form a connecting link between the areas on the east and west. A cross connection of some sort must in the future become immensely valuable, since the steepness of the slopes prohibits any other east and west link within a reasonable distance. This shore drive would furthermore preserve the banks of the lake to the city for all time and prevent private exploitation in a manner that might injure the entire section. And, to put the aesthetic element last, as the town planners have fallen into the habit of doing, this shore drive has the possibility of becoming a feature of very great charm, one that will attract to the region a considerable and desirable volume of motor and other traffic.

The community center is placed at a point which combines the geographic location needed for such a gathering place, with other desirable elements. It holds the salient point on the shoulder of the hill, where grades are least difficult to manage; it will witness the passage of nearly all the through travel of the section; it commands a magnificent view, which should in itself prove a magnet to attract the strolls of the villagers. To enhance the charms of this outlook the side of the square toward the lake will be left open and treated as a public terrace. Footpaths will also be brought down the steeper slopes of the hill toward the center in order to provide easy crosscuts and thus make it readily accessible for pedestrians, shoppers and strollers.

The secondary streets are, in the majority of cases, contour roads. Looked at merely as a paper plan, the layout is definitely lacking in cross connections. But, studying the topography, one realizes that gradients so steep as these would be impossible for any but travel on foot, and that to create roadways suitable for vehicles would entail expenses quite prohibitive in a development of this character. The footpaths just mentioned are therefore by way of a compromise to break up the long blocks.

When it was first proposed to develop the lovely little grove which is now Nashoba Place in the manner of a close, it was an open question whether or not such an arrangement would appeal to the American tastes. Experienced real estate men have told us repeatedly: "First of all, give each one his full share of frontage on the building line. The American loves his look at the asphalt." Mr. Atterbury had faced this situation before in the planning of Forest Hills Gardens. There, despite pessimistic views as to American discrimination, groups involving so-called "rear" housing units were liberally used, but with some fear and trembling for the outcome. Actually, the very first sale was a house that had greater setback, less

GROUP OF HOUSES, INDIAN HILL DEVELOPMENT



SECOND FLOOR PLAN, HOUSE OF TYPE N2, INDIAN HILL, GROSVENER ATTERBURY, ARCHITECT.

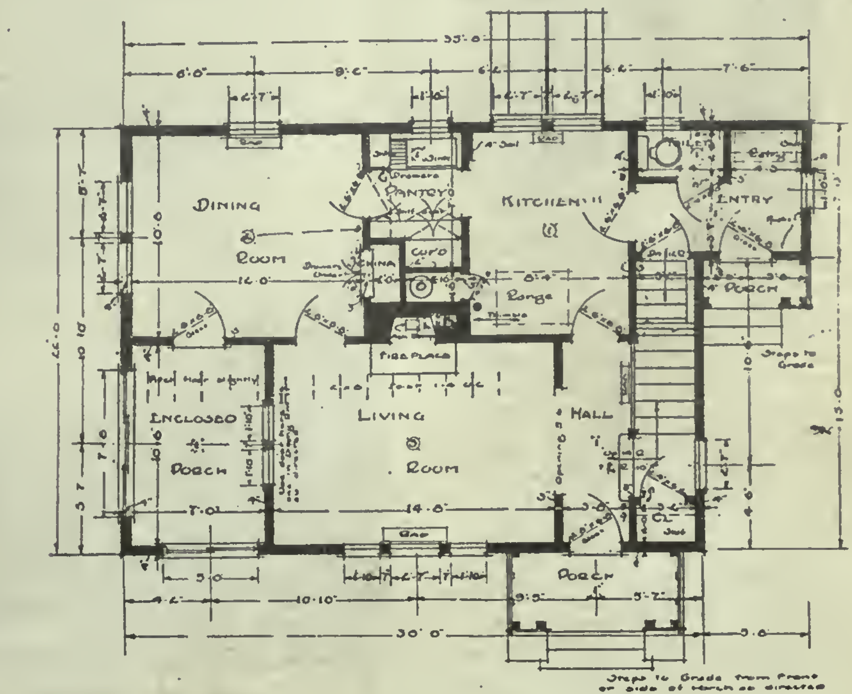
view of the asphalt; from that day on there has never been a doubt of the saleability of grouped units in Forest Hills.

At Indian Hill the question was reopened in a development of a different character. Here the provision of public amenities was to be more limited, the cost of private houses far less, the whole project more circumscribed by financial limitations. Yet here, too, where the very modest little house could rely upon little landscaping or "trimmings" to dress it up, the result has been identical with that in Forest Hills. Faith has been justified in believing that in most cases the buyer (be it of a house to cost $3,000 or $10,000) needs only to be shown. True, he lacks usually in both cases the imagination to see it for himself, exactly as he lacks the training to read an architectural elevation, but given some one to put the demonstration on the ground before him, and perhaps to explain a few of the whys, he is by no means slow to grasp the truth and to act upon it. Nashoba Place has accordingly been successful from the first; fully occupied, tastefully planned, delightfully sheltered, it already has some of that quality which, a few years ago, one sought vainly in this country and found only by travelling to England or Germany.

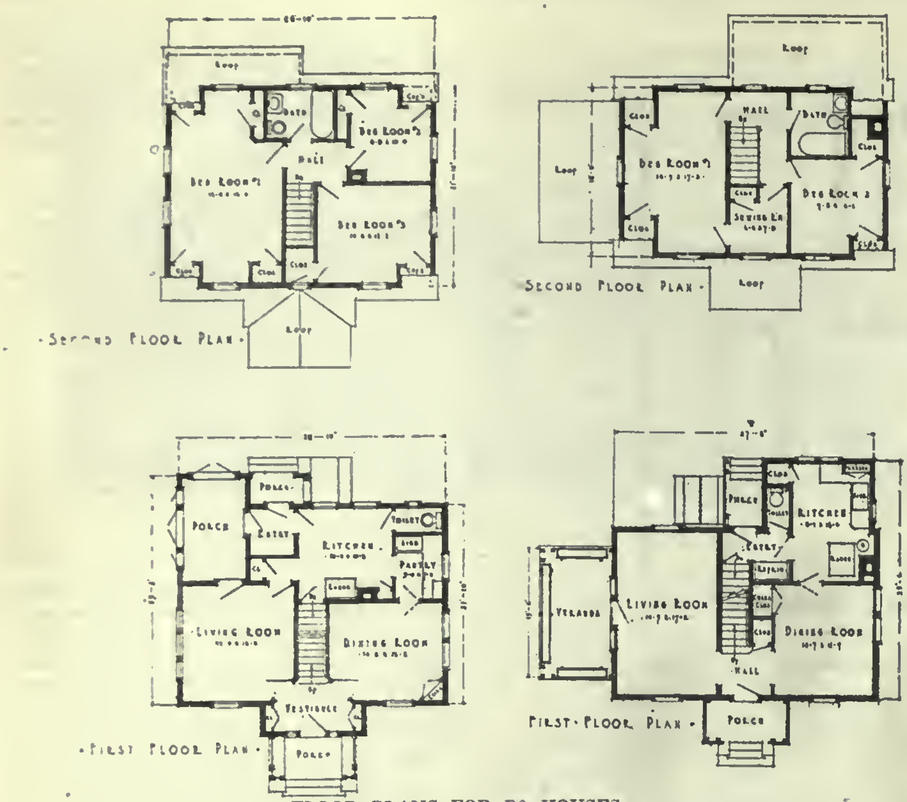
Construction work at Indian Hill has heretofore been confined to dwellings—some fifty-eight of them, built in two operations during the summers of 1915 and 1916. Enough has been done to give a suggestion of the ultimate look of the town—white walls seen among the trees, roofs grey green to unify the composition. The white was selected because of its consistency with New England traditions, because of its effectiveness, viewed from close at hand or from a distance, and because, unlike any other color, it can be repeated in a great number of cases without becoming tiresome (witness the delightful village of Whitinsville, also in Massachusetts). Slate was chosen for the roofing material because of its economy, its fire-resisting qualities, and because the color is good in itself. The roof material is the same throughout, as we have said, to bring unity into the composition. Where a collection of houses can be seen all together and from a distance, this common bond between the individual units is of the greatest value; it is like the family resemblance that marks them all one kindred; it is like the soldier cap that transforms the gang of boys into a regiment. Only by this and similar evidences of collective planning can there be produced dignity and carrying power in an aggregation of which the units, taken singly, must be too small or too insignificant to be effective.

This problem is peculiarly pressing at Indian Hill, since the number of buildings other than tiny cottage units, is at a minimum. For, by a curious psychological kink, the grouped party-wall dwellings that are the rule in English garden cities that are eminently successful at Forest Hills Gardens, are usually rejected with scorn by the industrial worker. He pridefully insists that his dwelling (to cost one-third as much as those, for example, at Forest Hills) shall be placed on its own lot, with free spaces all around, and shall be guarded to the last foot from any loss of power in its proclamation of individual ownership. Even the two-family semi-detached house, although planned to give perfect privacy, exposure and open spaces, does not as yet appeal strongly to the buyer, except in special circumstances of relationship or a David-and-Jonathan intimacy between two families.

Further development will, of course, work vast improvement in that there are already provided site reservations for several buildings of adequate mass in different sections of the property. There is the dining hall at the front of the streets as one enters Indian Hill from the plant; the Satucket Inn, really an exalted boarding house for bachelors, embodying the features of a club; a similar institution for the bachelor girls of the office force, a chapel, a recreation hall. Considering that these are quite apart from the buildings that will form the three-sided enclosure of the community center, we may feel that the amount of reservation for larger buildings is generous enough to go far toward



FIRST FLOOR PLAN HOUSE OF TYPE N2, INDIAN HILL, GROSVENER ATTERBURY, ARCHITECT.



FLOOR PLANS FOR D3 HOUSES.

overcoming the handicap of the minuteness of the individual units.

When the time came for naming the streets, the cue from local tradition was obvious. Upon Indian Hill, at the head of Indian lake, one would hardly impose an assortment of Broadways, Main streets or Grandviews. On the other hand it was comparatively simple to find Indian names which would respect tradition, sound well, and at the same time possess some distinction of their own. The first selection of names proved that the danger of a little knowledge was no more absent from this than from other pursuits. An expert Indian lore, called in to viser the list before final christening found that half the names were distinctly applicable to the ocean and its shores. This naturally demanded revisions in which "Big Wave," "Long Beach," and the like were exchanged for names which signified "Great Oak," "Open View," and so on.

In a countryside as open and unrestricted as in Indian Hill to-day, it would not be surprising if it were difficult or impossible to prove to the promoters the wisdom of large reservations for park areas. Fortunately this has not been true. It is the policy of the Indian Hill Company to preserve generous tracts of high, wooded land as a playground for the villagers; certain parts of the lake shore will doubtless be developed for bathing, boating, and water sports, and over along the east base of the hill will be the general recreation center. A comparatively slight amount of modeling will make the side hill into a natural amphitheatre, before which will be spread out the baseball field, the running track and their adjuncts.

Beside park areas for the general public, serious consideration is being given to the question of providing small parks in the interiors of various blocks as a play space for the children from the homes surrounding.

The numerous advantages of this system—safety, accessibilty, economy of land value, ease of supervision—are all so familiar and so generally recognized that comment is uncalled for. One special feature might be noted, however; as an exceptional opportunity. The higher portions of Indian Hill contain several excellent springs which, unused, might become troublesome. They must be controlled by piping into the storm sewer. To do this and nothing more would appear to be neglecting a splendid opportunity. Piped into the private parks, springs would, for a ridiculously small outlay, afford the bit of quiet water that would be the completion of the picture, the final element of charm usually left out in such cases because too expensive. The older boys and girls can swim in the lake; here the younger children could wade and splash and have a generally wonderful time. For their sakes, if for no other reason, the springs should not be consigned to waste their streams of pure water forever unhelpfully into a sewer.

Certain parts of Indian Hill are beautifully wooded; there are several fine specimen trees worthy to form landmarks; elsewhere the planners have started to make good any tree deficiencies. Not only have they adopted a programme for tree planting along the highways, but included in the purchase price of every house is a small amount representing the begining of a landscape treatment for that particular lot. The amount is small because the operation is a wholesale one; the results have a unity and breadth of scale which would be impossible were the planting left to individuals. This is by no means a criticism of the individual enterprise and taste of the owners; it means simply that in this department, as in others, the advantages of collective planning are apparent.

Buyers at Indian Hill have every reasonable assurance of the stability of their purchase. They know of the substantial materials that have been built into their houses (brass supply piping and copper flashings are not used by the jerrybuilder), and they know that no man can plant next door a factory or a store or a saloon. In other words, the property is all sold under carefully considered protective restrictions, which are accepted and recognized by the purchaser as equally valuable to themselves as to the company.

Terms of Purchase

The Indian Hill Company requires from the purchaser an initial payment of a certain per cent. of the purchase price, whereupon a conveyance of the property is made. For the balance of the purchase price the purchaser gives two notes, one

STREET SCENE INDIAN HILL DEVELOPMENT

for $1,000 payable in twelve years at 5 per cent., and another for the balance of the purchase price payable on demand, with interest at 5 per cent., both notes being secured by a purchase money mortgage.

The purchaser gives also a supplementary agreement to the effect that he will purchase in a co-operative bank five shares, and will continue payments thereupon until his deposits shall have matured in the sum of $1,000, which in local banks, at the prevailing rate of interest, takes place in about eleven years and ten months. This insures the payment of the twelve-year note according to its terms. It gives the purchaser a feeling of independence, inasmuch as he does not make periodical payments on the principal to the company, and enables him to become acquainted with co-operative bank methods.

In consideration of this agreement the company agrees not to make demand upon the demand note as the purchaser shall continue to make monthly payments in accordance with his agreement to the co-operative bank. The company further agrees that if he shall die or become incapacitated within twelve years —provided that at the time he shall not be over sixty years of age—it will accept the surrender value of his co-operative bank shares in full payment of the time note. The result of this agreement is that the purchaser may be assured that at the end of twelve years, or upon his prior death, a sufficient proportion of the purchase price will have been paid so that he or his estate will then own the property free of all encumbrances except a first mortgage for not over sixty per cent. of the value of the property so that at his option he may resort to a bank for a mortgage and be entirely independent of the company.

The company gives each purchaser a schedule showing the required monthly payments. The following table is a reproduction of one which was given to a purchaser of one of the 1915 houses, and illustrates very well the method of financing the purchase of an Indian Hill house:

Your total purchase price is	$3,851.50
You have made a first payment of 10%	385.15
You are borrowing on mortgage the balance ..	3,466.35
The amount due in 12 years, secured by time note, is	1,000.00
The balance secured by demand note is	2,466.35
Your monthly interest during first 12 years will be	14.45
Your monthly payment to co-operative bank will be	5.00
Your total monthly payments during first 12 years	19.45
Your monthly interest payment after 12 years will be	10.30
Total loan	3,466.35
Five per cent.	173.32
1-12	14.45
Demand loan	2,466.35
Five per cent.	123.32
1-12	10.30

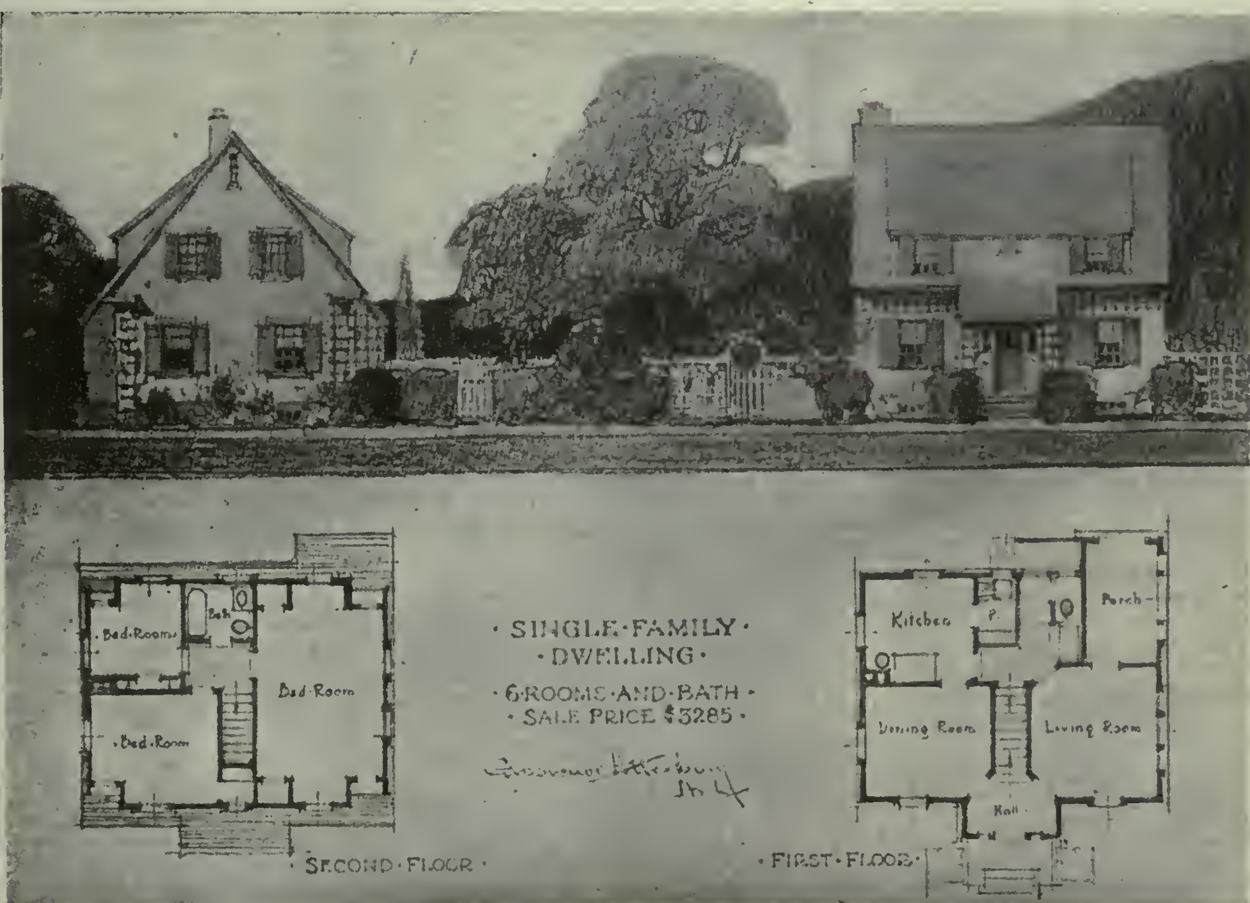
By following the table above, a prospective purchaser may start with the price of any available house and compute the amount of the monthly payment which he would be required to make.

The purchase price represents the actual cost of the house and land without profit to the company. The original purchase price of the entire area was divided by the number of feet in the tract to determine the base price per foot. To this was added a pro rata proportion of the cost of improvement such as sewers, highways, sidewalks, engineering expense and architect's fees.

In the case illustrated above, the cost of the land was $685 for a lot containing 6,850 square feet. To this figure was added the actual price of the house, without profit. This included the expense of the building, heating, lighting, plumbing, piping, hardware, fixtures, papering, window shades, screens, concrete cellar floor, granolithic walks, rough grading, finish grading, planting and clothes reel.

Individual Houses—Costs

Regarding the houses themselves, the plans and photographs reproduced herewith speak as clearly as any description. They could have been built more cheaply, but materials would be inferior; the costs could have been less in 1915, but



SINGLE FAMILY DWELLING, INDIAN HILL, GROSVENER ATTERBURY, ARCHITECT.

greater in 1925. In other words, the company has regarded the project as an investment for its own members, and in this aspect the long view of the transaction is the only justifiable one.

The costs of these houses individually shed an interesting illumination upon comparative prices of building as between 1915 and 1916. For instance, the constructional cost of the six-room house known as N2 has jumped from $3,188 in 1915 to $3,791 in 1916—an increase of nearly 19 per cent. The other types show similar results, though not quite so exact a comparison is possible, since certain changes were made by way of added features, the demand for the houses of ampler accommodations more than offsetting the burden of increased cost.

As to the general costs of a development such as Indian Hill, we find that the improvement of this acreage, that is, sewer, sidewalk and road building, tree planting and seeding, have amounted to just about 7 cents per square foot. This rate does not take account of overhead and administrative costs, which were not available. The amount chargeable to each of the fifty-eight houses built thus far, for town planning and architectural services, has come to about 2 per cent. This burden, horeover, light as it is even now, rests most heavily upon these first groups and will decrease still further with the progress of the development.

Any visitor to Indian Hill who would visit the interior of these cottages with a spirit of curiosity, or perhaps a touch of condescension as to their furnishings, is likely to receive a sharp mental jolt. The company, it is true, decorated and furnished a couple of houses to act as friendly counsellors to the others, but discounting this aid, it is only just to say that the average of taste displayed in these homes is remarkably high. There is very little overcrowding; the mass of gimcrackery is conspicuously lacking; there is discrimination, selective choice, and restraint everywhere. If one has sometimes been downcast by the bedevilment often worked by owners of mansions in their furnishings, let him turn to industrial cottages such as these and be encouraged.

FACTORY COSTS

By M. M.

British factory owners, it is frankly recognized, must begin in earnest to prepare themselves for the coming trade war if they would win in what promises to be a severe struggle, and many large houses are already considering the question of cheap power and fuel as one of the principal problems to be attacked. By the courtesy of the parties concerned, the Empire Resources Development Committee, which advocates the centralization and improvement under state assistance of power plant, offers the following interesting example of what may be done in fuel economy. It is that of a small glass works, the power for which is taken from a local power company at 1d. per Board of Trade unit. The glass furnaces are fired by producer gas of 130 B.T. units, the daily consumption be-

power charges work out at about $30,000 per annum, while the expenditure on coal by the producers is about $25,000. By means of a low temperature carbonization plant is proposed to do away with the burning of raw coal in the boilers of the power company and in the furnaces of the glass works. The gas produced from carbonization, although really a by-product, available for general use at a very low charge, has a B.T. unit value of 300 and is practically pure, so that 3,000,000 feet would do the same work for the glass company as the 6,000,000 feet now consumed, while the charge of 2d. per thousand feet (for the larger quantity) instead of 2½d., would show a saving of at least $50,000 per annum. Furthermore, the price charged to the power company would allow of a reduction of a ½d. per unit, thus showing a further saving to the glass works of $15,000 per annum. This statement of the case takes no account of the smokeless fuel, oil fuel, aniline dyes and other products, of which the country is in great need; but it is claimed by the Empire Resources Development Committee that, by suitable state action in relation to coal carbonization, a large revenue might be obtained towards the cost of the war without recourse to more disquieting expedients.

BRITISH MADE GLASS

By M. M.

At the last British Industries Fair held in London there was much evidence as to the marked advance shown in the manufacture of chemical and medical glass and porcelain. The exhibits included every description of laboratory glass, beside rod and tube, electric bulbs, engineering glassware, lenses and miners' lamp glasses. The specimens displayed, with two exceptions, included products from the fine modern factory of the Wood Bros. Glass Works Co., Ltd., Barnsley. Woods also exhibited surgical glass—another class of work to which glass makers have had to adapt themselves since the opening of hostilities, and lamp blown ware. Regarding the last named, a model glass house was organized and controlled as a department of the Sheffield University by Dr. W. E. S. Turner, which is now one of the centres in England for the training of pupils in the manufacture of scientific ware from glass tube by means of the blow-lamp, and similar efforts are being pushed in London and elsewhere, though in many cases they are carried out in the works of enterprising glass makers. It is not a new business in Great Britain, but it had been allowed to dwindle away until, in the days immediately preceding the war almost the only use made of lamp work in our glass factories was for repairing or touching up purposes.

ing about 6,000,000 feet and the cost 2½d. per thousand feet, exclusive of wear and tear charges, the coal used per day being about 50 tons. The total

In the summer of 1914 there was not a single manufacturer of laboratory glass in Great Britain. The whole process, the knowledge of which had been gradually built up by Germany during the past half century, had to be discovered and workers specially trained. At the fair no fewer than sixteen firms exhibited laboratory glass; six, glass rod and tube; twelve, surgical glass; three, laboratory porcelain; six, lamp-blown ware; three, lenses, and two miners' lamp glasses. And let it be remembered that every exhibitor had to be the bona fide maker of the goods shown. Two years ago British laboratory glass equalled, and often excelled, anything formerly obtained from Jena as far as the quality of the metal was concerned, and a year ago a great improvement was to be noted in the finish. The feature of this year is that the annealing difficulty seems to have been overcome, thus clearaway practically the last hindrance to the production in this country of chemical glass equal to the Jena article in every sense. In porcelain ware the same encouraging advance is to be noted. The whole wide range of the Royal Berlin productions has been gone through—Germany formerly satisfied our laboratory porcelain requirements to the extent of 90 per cent. from the Kaiser's own factory—the results being excellent in quality and finish.

The great point is that so far British prices compare very unfavorably with those of Germany, though this is in part, of course due to war conditions and will, in a measure, rectify itself. Laboratory glass is from 100 to 150 per cent. dearer, and porcelain about 50 per cent. dearer.

CANADIAN BOATS READY IN JANUARY

Hon. C. C. Ballantyne, Minister of Marine and Fisheries, has practically completed his work in London in connection with shipping and trade matters. His visit has bee of primary importance to the development of the Canadian shipbuilding industry. Next January, Mr. Ballantyne says, the first large Canadian government cargo steamers will be in commission, working in conjunction with the Canadia government railway system. The cargo boats will be fitted with cold storage facilities for the conveyance of meat, fish, and chilled rooms for fruit and dairy products. All boats will be under Canadian registry, and the rates will be controlled by the government.

While in London the Minister secured the release of a number of coal and ore-carrying vessels for the Canadian trade to keep the steel industries in operation. He expects the Canadian government will place a mill in operation next Spring. He also investigated the possibility of a development of the Canadian fish trade in Britain. Lack of cold storage facilities here is the greatest drawback to the frozen fish trade.

Haileybury, Ont.—Construction work by the Kipawa Fibre Co., at the site of its large new plant to the south of Lake Temiskaming is well under way. It is proposed to harness something like 4,000 of the 20,000 available horsepower for the time being.

Corrosion of Iron and Steel, and Its Prevention

Perhaps the Most Pathetic Feature of Man's Existence on This Planet is Illustrated by the Contrast Between the Immense Metallurgical and Manufacturing Industries Based on Iron Ore, and the Loss of Finished Metal Due to Corrosion

Being No. 7 in a Series by Abe Winters

ANOTHER fact which is well founded is that the presence of free iron has a marked effect in producing a precipitation of a vapor or suspended matter in a gas. It follows, therefore, that if a metal be heated in the presence of a vapor under such conditions that the gases or vapor contained within the metal are in part liberated; then, as the liberated gases or vapors contain some free ions, they will cause the precipitation within the pores of the metal and on the surface layer of a portion of the external vapor in which the metal is heated.

That all materials have a definite vapor tension is well known, this tension depending mainly on the nature of the material, the nature of the surrounding materials, the temperature and the pressure. It therefore follows that under all conditions all substances are surrounded by a certain amount of their own vapor. The vapor can be increased in amount by increasing the temperature and decreasing the pressure. Zinc vapor can be produced in several ways from zinc. If molten zinc is boiled in a reducing atmosphere, vapor is given off rapidly, and if heated iron is brought in contact with this vapor sherardizing would take place. This method is neither convenient nor economical because of the waste of zinc. The most practical and economical method is to use zinc dust, which is obtained as a by-product of a zinc smelter. This dust is practically amorphous, and each particle consists of a small inner particle of more or less pure zinc surrounded by a thin coating of zinc oxide. This oxide is very inert compared to metallic zinc and has a high melting point. It therefore is very advantageous in the process because it not only keeps the particles of zinc separated but allows the spheres of vapor surrounding them to act independently with a high vapor tension and permits the temperature to be raised beyond the melting point of zinc without its becoming molten. Therefore the percentage of inert material in the zinc dust plays an important part in the process.

Temperature and Time Important Factors

Temperature and time are factors which, depending upon each other, are very important in the process of sherardizing. They depend on the choice and quality of zinc dust used and also on the requirements and physical properties of the sherardized material. According to authorities on vapor tension, with an increase of temperature from 325 to 375 deg. C., the relative vapor tension increases 14 times and from 375 to 425 deg. C., the relative vapor tension increases 14 times and from 375 to 425 deg. C. the relative vapor tension increases 92 times. Zinc boils under ordinary pressure at 918 deg. C., and the boiling point under vacuum is reduced to 548 deg. C. Iron on being heated from 500 to 600 deg. C. in vacuum gives off gases readily. Therefore, it is quite clear that in vacuum the conditions are best for sherardizing. Since articles of different size, shape and character are treated, if each were given its ideal condition of temperature and quality of zinc dust, the time of treatment of all would be alike, but this is not practicable, for it is easier to vary the time of the process than the other factors. It is possible to obtain almost instantaneous sherardizing in the case of wire heated to a high temperature and allowed to pass through zinc dust at normal temperature. Not only the time of heating the article during process should be considered but also time of cooling, slow cooling is preferable for two reasons: First, to prevent loss from exposing hot zinc dust to the atmosphere (the metallic zinc particles would quickly oxidize): second, to prevent the articles being chilled too quickly. An article to be sherardized must be regarded first in respect to its ability to absorb zinc vapor, and then the condition under which zinc produces vapor at the highest tension. The most favorable condition under which the given article will absorb the most vapor must be obtained. In some cases it will be a selection of temperature or pressure; in some cases it will be the treatment of the article, as annealing, or the treatment of the surface mechanically (sand blasting or tumbling), or a chemical treatment such as pickling. A brighter metallic coating is obtained by using the manufactured zinc dust than with the blue dust, which is a by-product, the latter can be used with a lower metallic percentage and does not require as long time in processing and cooling and there is less danger of fusion of zinc due to slight overstepping the temperature limit.

When the article sherardized will be subjected to sharp bending or considerable variations of temperature, the thickness of coating will be limited, for zinc, being more brittle and having a different co-efficient of expansion than iron, will separate from the iron under these extreme conditions if too thick a coating is applied. Perhaps the greatest advantage of sherardizing, which makes it adapted where other processes are impracticable, is the fact that it gives a uniform coating over the entire surface, such as the inside and outside of hollow articles, on threads of pipes, bolts, nuts and on woven wire cloth. Because of its great adhering and alloying properties with the iron, the coating makes a very good basis or intermediate coating when plating upon iron with such metals as copper, tin or nickel, but combinations of this kind are not advised if most efficient protection from corrosion are desired.

According to Prof. C. F. Burgess, of Wisconsin University, if a sherardized surface is scratched by a file and exposed to the alternate action of air and water, rust will form in this scratch, filling it up and bridging it over and apparently bringing the action to a stop. This rust comes from the iron liberated from the electro-positive coating rather than from the underlying iron. Thus, a defect in a sherardized coating apparently tends to heal itself over while with other forms of covering the defect becomes exaggerated. Professor R. B. Leighon and Prof. H. A. Calderwood state that a sherardized coating should afford protection over a longer period of time and yield less readily to corrosion than an electro-galvanized surface, due to the fact that the former is less electro-positive to iron than the latter, their potentials being given as 0.296 volt for sherardizing and 0.472 volt for the electro-galvanizing. An abrasion test by these gentlemen, on a sherardized sample having three times the initial weight of zinc before the test showed twenty-two times as much after test as the electro-zinced sample, while another with about one and three-quarters times as much as the best electro-galvanized at the beginning had five times as much at the end, showing that sherardized surface is much more resistant to abrasion.

Commercial Requirements

In general, a protection against corrosion should conform to several conditions for commercial work. Prominent among these conditions are the following: The coating must be durable and of a reasonably permanent character. It must be conveniently produced at small initial cost and with low operating expense. It must be adapted to the particular requirements of selected products. There must be uniformity of results and conditions governing same. The coating must be controllable by predetermination of conditions affecting the production of the coating. The coating must have certain physical properties relating to strength or elasticity which are conclusive to resistance to wear or exposure to the elements, and the finished article must be of pleasing appearance.

The question may be asked why copper is being used so extensively on munitions for the British army. The answer is simply because the British specifications call for copper, and not because copper has been determined the most efficient protection for iron or steel military supplies. Iron and steel military supplies are being treated by immersion in phosphoric acid solution in the United States, but not because the U. S. Bureau of Standards has pronounced the process most effective. The bureau has recommended zinc in some forms. They do not specify any particular method of applying the zinc, but zinc alone is advised. Zinc on lead, copper or tin over iron or steel is not as reliable as a simple coating of zinc, a subsequent covering of lead has been found beneficial and such coating will withstand very severe salt spray tests. Bituminous paint over the zinc coating has also given very excellent satisfaction. Black nickel should be deposited over zinc to be effective as a protective coating. Nothing is gained by nickeling over zinc except a finish which will remain brilliant for longer period, the durability of the coating is not increased appreciably. The investigations now in progress by the United States Government will no doubt result in the production of a standard rustproof coating for iron or steel and when adopted by the industries the process should actually revolutionize metal finishing with reference to iron or steel products.

AEROPLANE MAKING GROWING INDUSTRY

In January of last year the Imperial Munitions Board, through Canadian Aeroplanes, Ltd., commenced the construction of aeroplanes for training purposes in Canada at the national factory, where the output of flying machines has now grown to a substantial total. The present capacity of the plant is 300 machines per month, which with the spares turned out is equivalent to 350 machines monthly.

The total number of machines manufactured to the end of last May, together with the spares, was 2,000.

The number of employees engaged at this factory is 2,150, and recently the plant has been engaged in constructing a number of bombing planes for the United States navy, showing how closely the two allied countries of North America are co-operating in their effort to beat the Hun.

New Type of Engine

The Imperial Munitions Board has placed a contract for the construction of an important number of the latest improved type of high power airplane engines to be used in equipping fighting planes for service at the front. This is a somewhat surprising development for a country so young as Canada in the airplane-making industry, as this particular design of engine represents the highest class of workmanship attained in any machine of this nature yet produced.

No engines are manufactured at the national plant, but are supplied from various outside sources and assembled and mounted there. The principal materials entering into the construction of the machines—apart from the engines—are spruce, fir and high grade linen, all of which are used in fabricating the wings. A large number of women are employed at the plant in this capacity. The bodies of the machines are composed of the wooden frame covered with canvas. The seating space is protected by an aluminum frame and the propellers are made of mahogany.

The board up to the end of May has contracted for the cutting of 248,000,000 feet of spruce logs, from which it is expected to secure 43,000,000 feet of sawed airplane lumber, in addition to 5,700,000 feet of rived spruce for the British Air Board, and required for the construction of airplanes.

Further contracts have been made with approximately seventy mills in British Columbia for their total output for extended periods of clear Douglas fir for use in the construction of airplanes.

In connection with the training of Canadians as airmen the Imperial Munitions Board has secured grounds, erected building and furnished equipment necessary for the carrying on of the work of the Royal Air Forces at its various flying centres, including Camp Borden, Armour Heights. Leaside, Camp Mohawk and Beamsville.

BITUMINOUS COAL TO BE OF GOOD QUALITY

More vigorous regulations than those heretofore issued to insure the production of clean bituminous coal have been made public by the United States Fuel Administration.

No bituminous coal will be permitted to be sold, shipped, or distributed if the same contains such quantity of rock, slate, bone, sulphur, fire clay, shale, or other impurities that it would not have been considered merchantable prior to January 1, 1916.

May Prohibit Shipments

Shipments from bituminous coal mines in which the coal is naturally of such character as to be unfit for market may be prohibited by the Fuel Administration. Operators also of bituminous mines whose products are capable of being made merchantable by complying with the requirements of the Fuel Administration in regard to the removal of impurities and who fail to comply with those requirements, will be required either to unload and clean such coal, if it has been loaded into cars or bins, or to deduct 50 cents per ton from the Government price. In the event of repeated violations on the part of such operators, such further action will be taken by the Fuel Administration as it may deem advisable.

The enforcement of these orders devolves, primarily, upon inspectors appointed by the district representatives.

These inspectors are required to familiarize themselves with the conditions under which coal is produced and prepared for market in the particular territory to which they are assigned, and to advise mine operators and employees of such methods as the inspectors may deem necessary to bring coal up to the standard, to inspect coal mining operations in their respective territories, and to make daily reports to their several district representatives.

Copies of these reports, with the recommendations of the district representatives thereon, will be forwarded to the Fuel Administration for final action.

Determined to Increase Efficiency

The order evidences the determination of the Fuel Administration to neglect no means by which it can assist in increasing the efficiency of every furnace in every factory and in every ship devoted to the prosecution of the war.

The enormous increase in the demand for bituminous coal incident to the entrance of the United States into the war, encouraged the opening of numerous so-called coal mines, a large percentage of the output of which resembled coal solely in color. This product brought the same price on the market as clean coal. The inevitable result was a general deterioration in the quality of all bituminous coal put on the market, and a consequent proportionate decrease in the heat generated in the furnaces of the country.

The new order is intended to correct that evil. It was prepared after an extensive conference between representatives of the United States Fuel Administration and the district representatives, who, besides being representatives of that organization, are practically coal operators, and were selected by the operators of the districts over which they have jurisdiction as their representatives. This order, therefore, is expected to effect the object for which it was passed.

The United States Fuel Administration also made public an order under which operators of bituminous coal mines may receive a special allowance for coal mechanically washed or extraordinarily cleaned or picked in such manner that the fuel value of the coal will be substantially increased by the removal of waste and impurities. No special allowance, however, will be made for the ordinary method of cleaning or picking coal.

This order supersedes all prior orders on this subject, and becomes effective at 7 a.m., June 1, 1918.

Amount of Allowance

The amount of the allowance contemplated by this order will be determined by the Fuel Administration, and will be set forth in a permit to be applied for and obtained by such operator in conformity with the provisions of the order.

Applications for such permits must be made to the license section, legal division, of the United States Fuel Administration, and must supply the information indicated in such applications, forms for which will be furnished on request.

Will Return Profits.—Henry Ford, through his private secretary, announced that he will return to the United States Government all the profits he personally makes on war contract work. He added that he expected a number of the other stockholders of the Ford Motor Company would follow his example.

Theory and Application of Sectional Views

Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simple Type—Practical Course Prepared For Younger Men and Newcomers in Industry

Fifth of Series of Articles By TERRELL CROFT

Conventional Methods

REVOLVED sections are small views drawn within the outline of the object itself to show the construction of its members. In Fig. 16 the revolved sections M. N. and O, indicate that the portions of the object wherein these views are drawn are of circular, elliptical and channel sections respectively. These revolved sections are a great convenience to the draftsman, in that their use often enables him to specify in detail the construction of an object with only one main view and two or three revolved section views; whereas, without the revolved sections two or three complete views might be required. Sometimes, instead of showing the revolved section directly in the main view, the main view is broken to permit the insertion of the auxiliary section, as shown in Fig. 17.

Removed sections may be used where revolved sections cannot be employed effectively. Fig. 18 shows three removed sections which detail the construction of the rod. The removed sections are located outside of the outlines of the object. The plane at which each removed section is taken should be indicated by a section lines and letters, and the removed section itself should be lettered correspondingly. Thus, in Fig. 18 Section AA shows that a cut through plane A¹A¹ would disclose a hexagonal end view.

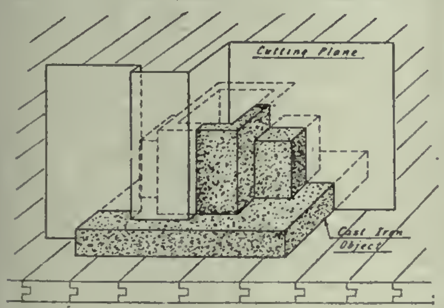


FIG. 15—NON-CONTINUOUS CUTTING PLANE.

A cutting plane does not, so it is assumed, cut through every member which it intersects. Thus there are certain objects which are practically never shown in section, though the cutting plane as indicated on the drawing passes through them. Some of these objects are: keys, bolts, screws, rods, shafts, studs, nuts, and spokes of wheels. A drawing giving an excellent example of this practice is that of the high-speed engine of Fig. 19, which is shown therein in longitudinal section. It will be noted that because of the fact that the piston rods, bolts, nuts, shafts and similar members are not shown in section, the drawing is much clearer and more expressive than it would be otherwise. This is in spite of the fact that a longitudinal cutting plane located symmetrically through the center line of the cylinder and the shaft would cut through the members above enumerated.

Assembly Section Drawing

Another good example demonstrating this principle is that of Fig. 20, which shows a uniflow engine cylinder in section. note that the piston rod, cylinder head, valves, bolts and nuts and certain other members are not sectioned. Fig. 21 gives a quarter section view of a roller bearing shaft plunger in which neither the shaft nor the bolts and nuts are shown in section, in spite of the fact that the cutting planes intersect them. The working drawing of a hand wheel is shown in Fig. 22. Note that in the sectional view to the right the upper spoke is not shown in section, although the cutting plane passes through its center. This Fig. 22 gives the accepted and correct method of rendering the sectional view of the pulley. The sectional view of Fig. 23, although it is theoretically correct for the pulley of Fig. 22 does not convey as definite an idea as to the construction of the casting as does the sectional view in Fig. 22. This explains why the method of Fig. 22 is used.

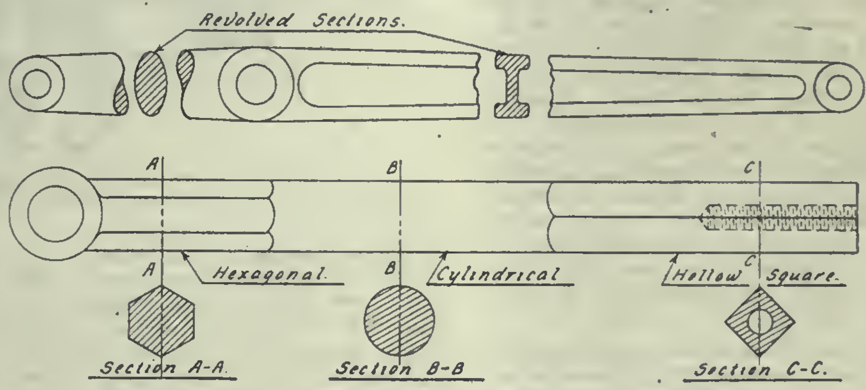

FIG. 16—ILLUSTRATING USE OF "REVOLVED SECTIONS."
FIG. 23—INCORRECT METHOD OF SECTIONING WHEEL SPOKE.

Webs are not shown sectioned even if the cutting plane passes through them. This principle is defined in Fig. 24F. Although the cutting plane AA passes through the center of the longitudinal web, the section AA shown at the bottom of the drawing indicates the correct method of rendering this web. That is, the web should be shown as if it were not cut through, because this method conveys a more accurate idea as to the actual construction of the object.

Section lining is usually at an angle of 45 degrees, although the lines may be drawn at some other angle if, to insure contrast, this is desirable. The drawing of the blanking-and-piercing die reproduced in Fig. 25 provides a good example of this maxim. Close examination of Fig. 25 will disclose that certain of the section lines representing steel are ruled at an angle of 45 degrees, while other steel parts adjacent to them are ruled at an angle of 30 degrees to insure the contrast just mentioned.

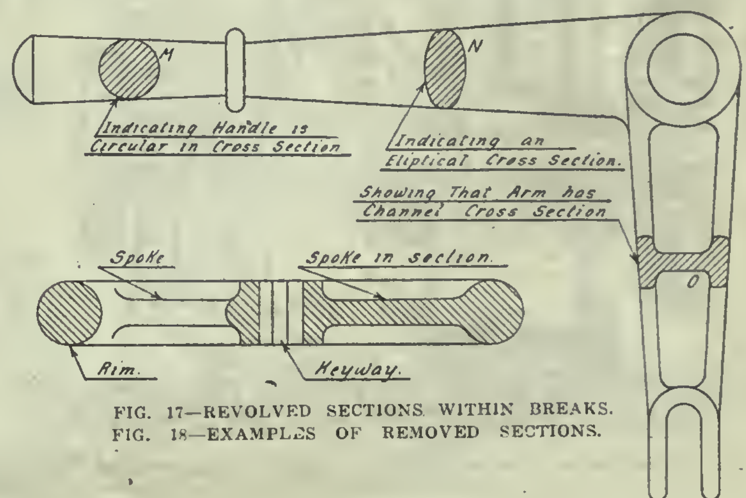

FIG. 17—REVOLVED SECTIONS WITHIN BREAKS.
FIG. 18—EXAMPLES OF REMOVED SECTIONS.

Drawing of Section Lines

The tendency of beginners is to draw section or cross-hatching lines too close together. Where the lines are too close together, not only is much unnecessary work involved, but the resulting appearance is not as satisfactory as when the lines are further apart. On working drawings, unless the area to be sectioned is very small the section lines should not be much closer together than 1-16 in. On sketches the section lines may be put in free hand. On tracings or ink drawings they should be ruled in, using a triangle as a guide. An experienced draftsman always spaces the lines with the eye. The numerous automatic section line spacing devices which are on the market are seldom used in commercial work. If the first few lines are spaced carefully the draftsman can with little effort, by referring to these as a guide, section the remainder of the area quite uniformly.

Often one sectional drawing may be made to detail completely the construction of an object. Consider the commutator core shown in Fig. 27. It is evident that the sectional drawing of Fig. 27 specifies completely the construction of this core. It is of course understood in a drawing of this character that certain of the dimensions represent diameters, and certain others lengths. Figs. 28 and 29 give two other good examples of sectional drawings which completely detail the construction of cylindrical objects.

Sectional views are of great usefulness in delineating power plant construction. If there were no such thing as a sectional view it would be almost impossible to show on a drawing the arrangement and construction of the equipment in a modern power plant. A typical transverse sectional drawing of a hydroelectric station is reproduced in Fig. 30. This discloses at a glance the principal constructional features of the station. Note that it is usual to take a section through one of the generating units. In Fig. 30 the section is taken through one of the water-wheel generators, and shows very clearly the construction and contour of the inlet and draught tubes for the turbine. A typical substation sectional view is given in Fig. 31. Here also the section is taken through one of the synchronous converters and shows its arrangement over the pit.

SMALL WORKSHOPS

By D. Street

The conviction of many people before the war that small factories would gradually be eliminated, that all industry would be carried on in factories of the largest size, and equipped in every way to ensure economy and rapidity of execution, has been disproved to some extent by the experience of the past three and a half years. The argument is sometimes used that small shops are a national asset, chiefly because they constitute an ideal training place for craftsmen, but small shops will not survive for this reason. Their value for training apprentices is undisputed, but modern industry has an economic basis. If the small shop meant a waste of labor and material they would have to go, indeed they would have gone long ago. Since the war started the small shops have proved proportionately as great an asset to the nation as the big concerns, and they have multiplied amazingly. All

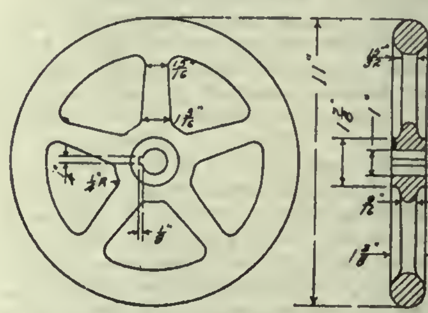

FIG. 22—WORKING DRAWING OF HAND WHEEL.

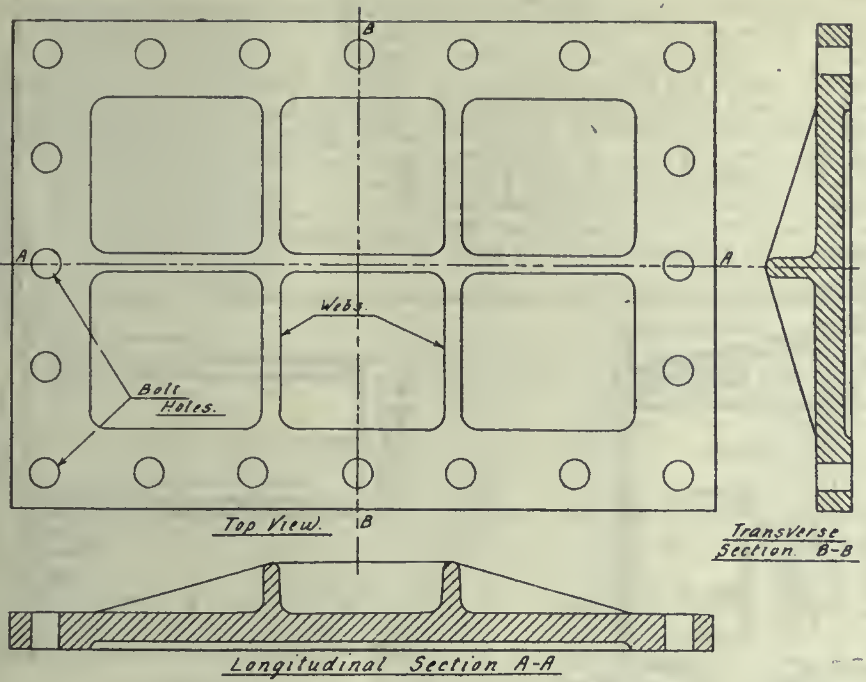

FIG. 20—GENERAL VIEW OF WORKING DRAWING.

over the country are small shell-making shops, and the work is turned out satisfactorily and quickly. The same may be said of the foundry trades. It is a fact that big engineering works that have well-equipped foundries and pattern shops often give some portion of their work to jobbing shops, and find that it costs them less than if the work was done in their own works, and this despite the apparent handicap of the small shop in the matter of machinery. There are many reasons why the extinction of the small shop would be regrettable, but there is fortunately every reason for believing that they will occupy an important place in the industrial system of the future.

Because the tendency of the time is towards standardization there is a fairly widespread belief that in a comparatively short time there will be no large general shops. The general shops, that is, the shops that will undertake any piece of engineering, and do not specialize in any way, have become fewer in recent years, but there will always be many of them. It ought to be remembered that very many of the large specialist firms have evolved from being general engineers. Indeed, the shrewd business man with sufficient initiative to run a small jobbing shop will gradually develop his business so as to cope with anything that may come along, and in course of time, because of the greater profits and the more regular flow of orders, he will specialize. To eliminate the small shop this type of man will have to be eliminated. There are men who are happier in supreme control of one or two men than as employees with a thousand subordinates.

The great usefulness of the small shop is in undertaking repair work. It may be true that if some part of a motor engine has to be repaired a duplicate part may be obtained by sending an item number to the maker, but it is not always convenient to wait for a few days. Again, when the part comes, some part of the engine has probably to be dissembled before the new part can be exchanged for the old. The standardizing of motor parts has not prevented the number of wayside garages from increasing. The same thing may be said for ship repair. Big vessels are, of course, overhauled in the big yards, but the smaller craft can be as cheaply repaired in the small place. Even more useful work than repairing is the work done for inventors. It would be interesting to know how many small concerns are kept going chiefly by inventive clients. The large firm is prepared to purchase a proved success, but it interferes with their organization, to experiment with an idea that may or may not be worth while. Of course, both for repair and experimental work there is practically no competition between large and small firms, and it may be admitted that it will become more and more impossible for men with small capital to compete in new construction with wealthy firms, who by subdivision of labor and automatic machines can cheapen production.

On the whole the management expenses of small firms are less than those of large firms, and there is the added advantage of unity and control. A great many large engineering works to-day are weighted down with foremen and managers. There is a false impression abroad that speeding up means multiplying the number of leaders. The small engineer is his own manager, and his interest is direct. He has cut out all waste, of which there is too much even now in engineering works, and a fair return satisfies him. This is especially true of hand work. There is every reason why a small foundry, pattern shop,

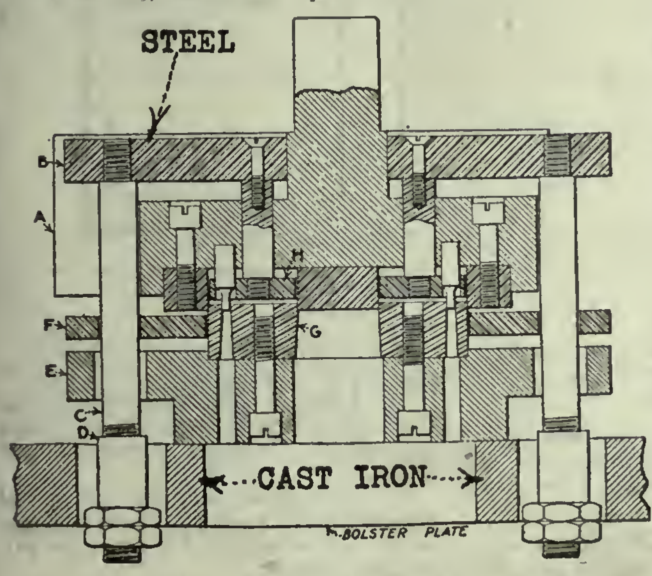

FIG. 25—SECTIONAL VIEW OF BLANKING AND PIERCING DIE.

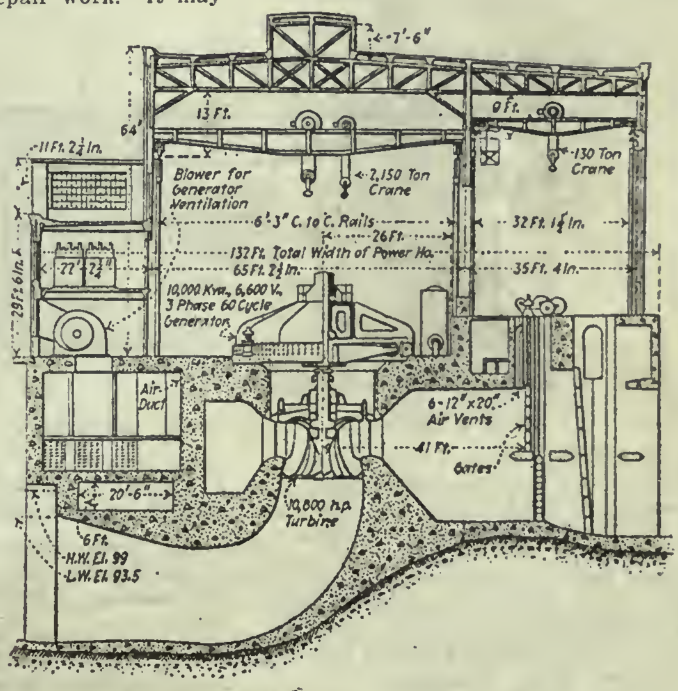

FIG. 30—SECTIONAL ELEVATION OF HYDRO-ELECTRIC STATION.

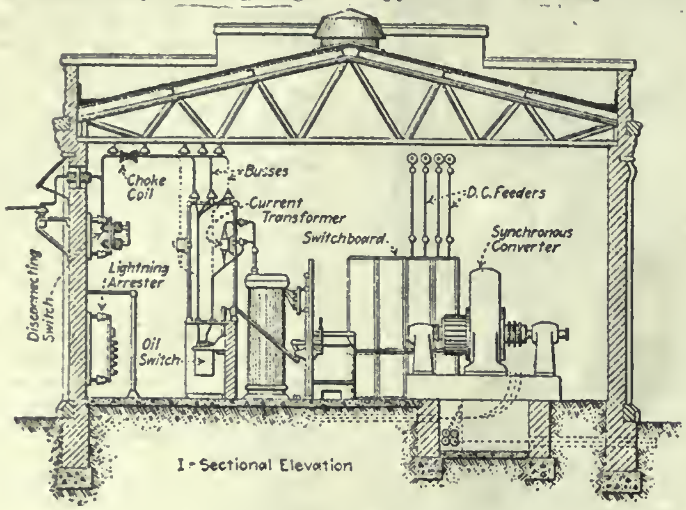
or fitting shop should turn out even cheaper work than a big shop, and it is acknowledged that the best controller of a big shop is the man who has served with a small firm.

It is quite probable that the development of industry in the future will take the form of large firms giving out a good deal of their work to small firms. It will probably be found cheaper to support separate concerns by ordering large quantities of parts from them although of course the work will be erected in their own works.



SUB-STATION.
FIG. 31—SECTIONAL ELEVATION OF SYNCHRONOUS CONVERTER

BIG SHIPBUILDING BUSINESS COMING

The National Shipbuilding Corporation has orders on its books for between $8,000,000 and $10,000,000 wooden ships for foreign account. These vessels will be built in Canada where the company has just secured control of the yard of the Three Rivers Shipbuilding Co.

Through the efforts of Newman Erb, chairman of the board, the National Co. at its American plant, located near New Orleans, will soon undertake the construction of small steel vessels running up to 3,500 tons deadweight. Next week it will launch the first of four steel tankers for the Mexican Petroleum Co., after which its activities will probably be confined chiefly to the wants of the United States Shipping Board and the Emergency Fleet Corporation.

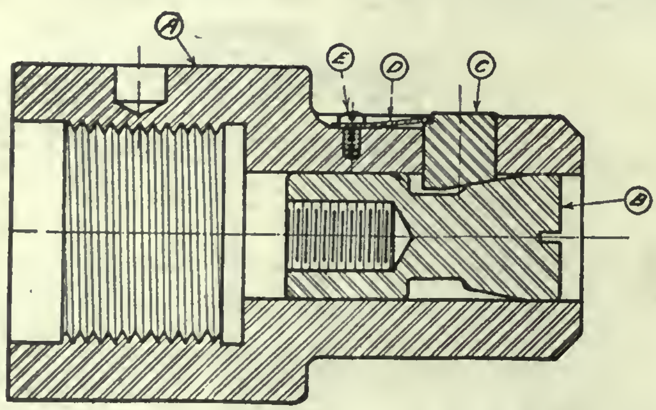


FIG. 28—DRAWING OF AN EXPANDING MANDREL.

In order that it might carry out its foreign contracts the National Co. has secured the capital stock of the Three Rivers Co., which has been building small wooden vessels for the British Government. The foreign orders in hand will keep the plant, having about fifteen ways, busy until the end of 1919.

The management of the National Co. has in mind the transformation of the shipyards into car shops should the shipbuilding industry show signs of lagging at the conclusion of the war. The company, in conjunction with its Louisiana plant, owns a canal, the operation of which may be taken over for the government by the Inland Waterways Commission, negotiations now being under way to this end.

TRADE INQUIRIES

The following trade inquiries have been received by the Department of Trade and Commerce, Ottawa.

593. **Tin caps for bottles.**—A large concern in Mexico would like to have quotations for supplies of tin caps or crown corks for bottles.

594. **Dry sulphite.**—A Mexican paper manufacturing company would like to get supplies of dry sulphite from Canada.

595. **Paper and pulp.**—A firm of Japanese importers would like to get supplies of paper and pulp. They would be glad to receive communications from Canadian manufacturers with regard to business either now or after the war.

596. **Asbestos fibre.**—A firm of Japanese importers would like to make arrangements for supplies of asbestos fibre after the war.

597. **Wire, wire nails, etc.**—A Japanese firm representing Japanese manufacturers wishes to correspond with Canadian manufacturers with a view to getting a supply of wire and wire nails either for present shipment or for business after the war.

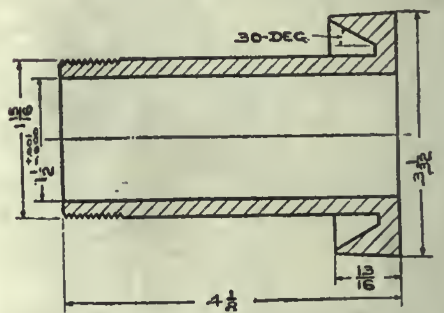

FIG. 27—COMMUTATOR SLEEVE DETAIL.

598. **Iron sheets.**—A Japanese firm of importers wish to communicate with Canadian manufacturers in reference to supplies of iron sheets after the war.

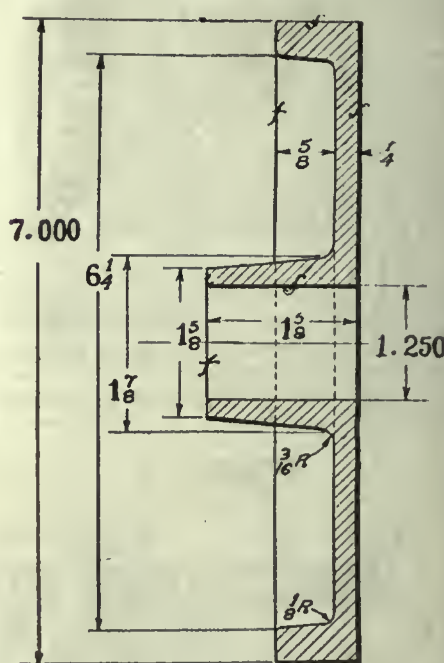

FIG 29—COMPLETE CONSTRUCTION SHOWN IN SECTION.

602. **Sulphate of ammonia.**—Large commission firm in Barbados is making inquiries for Canadian sulphate of ammonia.

603. **Galvanized buckets.** — Firm of manufacturers' agents in British Guiana would like an agency for Canadian galvanized buckets.

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

RECORD SYSTEM FOR PATTERNS

By Wilfred G. Astle

The following system of keeping a record of patterns, also indexing and storing them, will eliminate any delay or errors made in selecting the proper patterns from the store-room, and has been successfully used in the shops of a large electric railway system in Indiana.

Requisition

The first form required is a requisition (Illustration No. 1) and is issued by the foremen of the different departments when patterns are required from the storeroom. This requisition is first approved by the master mechanic, and is then turned over to the pattern storekeeper, who supplies the pattern. If the pattern is a new one and has to be made up, the requisition is then turned over to the foreman of the pattern shop, and is his authority to make up the pattern. When the work is completed he forwards the pattern to the pattern storekeeper accompanied by a pattern report (illustration No. 2).

Office Record

The office record is shown Form No. 3 (see illustration) and contains details of the make-up of the pattern and the metal from which the casting should be made and the approximate weight of one casting. This form also shows the location of the pattern at all times. In order to make this record complete, it will be necessary to arrange the pattern shelves so that they can be divided by partitions and numbered. Each pattern is given an index number which will correspond to the correct name.

Tag for Outside Work

When it is necessary to send any pattern to an outside foundry for castings, a special tag is used (Illustration No. 4) which consists of three coupons, and is fastened to the pattern. When the pattern is ready for delivery the first coupon is detached by the pattern storekeeper, and forms a record of the pattern sent as well as the name of the party receiving it, the date of delivery, and the name of the department ordering it sent.

The second coupon is detached by the foundry receiving it, and requests that the foundry check the number of pieces according to the memorandum attached

The last coupon remains with the pattern and is a correct record of the type, number of parts and number of core boxes as well as the correct name and the material to be employed in the casting. The first coupon, which is detached by the pattern storekeeper, is kept in his office and the record that it contains is copied on the permanent office record.

FRICTION AND LUBRICATION

By D. Street

The experimental results obtained by such well-known authorities as Stribeck, Heimann, Beauchamp, Tower and others prove that the view commonly held, that the length of a bearing should increase in proportion to the speed, is wrong; and that some modern methods of automatic and forced lubrication are essentially faulty. In the case in which one solid substance is rubbed, on another without the intervention of any unguent, it is well known that however smooth a metallic surface may appear to the eye or touch, its real condition when looked at under a microscope resembles that of a very rugged mountain system; the peaks and chasms on the two surfaces crash into each other whenever there is any relative movement between them. The molecules are also assumed to be in a state of constant vibration.

No one would expect that any regular system of laws could be deduced from such a process, as a complete molecular theory of matter would be required to rationalize these phenomena; nevertheless, certain rough generalizations could, however, be made, which are useful to the engineer; namely, that the co-efficient of friction increases with the load, that it varies with the speed of rubbing, being greatest when the motion is slowest, until, at the point where one body is just commencing to move relatively to another, a maximum is reached. The friction at this point has been cleverly called "striction" and has been investigated by a well-known expert, Rennie, who succeeded in obtaining values as high as 0.3 to 0.4 for the co-efficient of striction for iron upon iron.

In the ordinary case of a greasy shaft lying in its bearings at rest, if it be assumed that the shaft be of smaller diameter than the brass bush, it would only touch it along a narrow line at its lowest point. As soon as rotation begins, the shaft no longer remains on the bottom of the bush, but rolls up the slope in a direction contrary to that of rotation and the point of contact changes according to the speed of the load. As the former increases, the oil will necessarily be carried round with the shaft until it forms a film separating it completely from the brass bush. The pressure is greatest immediately in front of the point of nearest approach between the shaft and the bush, and falls to nothing immediately that point is passed, maintaining a constant pressure through the remainder of the bearing. At still greater speeds it has been ascertained that the maximum oil pressure diminishes and that the shaft takes up a more central position in the bearing. If the speed were infinitely great, the shaft would run quite centrally in the bush and the positions of maximum fluid pressure would be vertically about and below the centre.

The important physical results of these observations are that they enable engineers to determine upon the best position in the circumference of the bearings at which the lubricant ought to be applied. With ordinary automatic lubrication by cup and syphon, or by ring, or centrifugal method of supply, the oil should obviously be made to flow on to the journal where pressure is least, that is to say, the oil should be fed from a point situated in the top rear quadrant of the bearing when the shaft is loaded by gravity only, and the point should be further back the slower the speed becomes. When the lubricant is supplied under pressure by mechanical means, it must be fed in at the points of greatest oil pressure, in the bearing. In engine bearings fitted with forced lubrication this has been found not to be usually done by the makers who did not threfore get the full advantage of the system.

The next point is a description of the nature and magnitude of the frictional resistance set up between the shaft and the bearing when there is an abundant supply of lubricant completely separating the two, thus preventing any metal to metal contact. In this case friction is due to the resistance of the oil to shearing or transverse distortion. With a film of oil of uniform thickness this friction depends only on the area of oil to be sheared, the viscosity of the oil, its temperature and the thickness of the film. Unfortunately there are very few cases in engineering practice where a shaft rotates at such a speed as would insure a uniform thickness of oil all round. In the case of turbines, motors and mill spindles this may happen, but in most cases the shaft moves to one side by an amount which depends on the speed and on the load.

With a film of uniform thickness the friction becomes less as the thickness of the film increases, and it would appear that in the case of a shaft rotating eccentrically in its bush, the increased thickness on one side must compensate for the thinning on the other side. This, however, is not the case, for it has been found from the Researches of Professor Osborne Reynolds, of Owen's College, and Mr. Sommerfield, another expert, that what is lost in friction due to thinning on one side is greater than what is gained by the thickening of the oil film on the other side. On the whole, therefore, the friction may be said to be increased by the eccentricity of the shaft in the bearing. Any increase of speed tends to reduce this eccentricity of the shaft and as a consequence to reduce the friction. On the other hand, as the speed increases, the oil resistance increases. There can be no doubt that the greater the pressure on the bearing, the greater the speed is at which the co-efficient of friction has a minimum value. The conclusions which may be drawn are that the ordinary assumption of a constant co-efficient of friction is incorrect and that, as a matter of experimental fact, it has been proved to be by no means constant but dependent on speed pressure and on temperature.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

ELECTRIC SEAM WELDER

THE Thomson Electric Welding Machine Co. of Lynn, Mass., have developed an electric welder for seamed goods of all kinds. It is particularly adapted to the welding of the longitudinal seam on pieces such as cans, stove parts flat pieces, and will also handle rectangular shapes such as metal boxes. Electric seam welding is faster than lock seaming or soldering and produces an airtight joint.

The piece to be welded is secured in a specially designed jig on the low horn or arbor; pressure on the foot treadle engages a clutch of the driving mechanism which causes the welding roller on the upper horn to move forward. This is actuated by the movement of a screw. When the welding roller comes in contact with the stock the current is automatically turned on. The current passes from the roller through the metal to be welded to the lower copper horn, thence to the transformer, thereby completing the electrical circuit. The resistance of the metal to be welded generates a welding heat so that the pressure caused by the roller makes a continuous weld the whole length of the seam. When the roller has reached the end of the seam the current is automatically turned off and the roller returns to its original position. The welded piece is then removed from the jig and the machine is ready to make another weld by repeating the operation.

Clean sheet iron or steel can be welded up to 16 gauge and up to 24 inches in length, and brass can be welded of lesser thickness depending on the character of the metal.

The machine is equipped with a 15 k.w. transformer which can be furnished for 220 or 440 volt, 60 cycle, single phase, a. c. circuit. Direct current cannot be used. One phase of a two- or three-phase circuit can equally well be used. The machine is equipped with a voltage regulator in order to obtain the different welding voltages for different kinds and thicknesses of stock. The automatic switch is adjustable for different lengths of seams. In order to overcome the electrical loss created by the increased distance of the welding roller from the transformer, and the effect of the inserted stock to be welded, the machine is equipped with an automatic variable reactance which consists of a coil wound on an open iron circuit. As the stroke of the welding roller increases in length the reactance of the coil is gradually reduced mechanically by lifting a closed copper cylinder over the coil. The movement of this cylinder is proportionate to the movement of the roller contact. The electric motor which operates the welding roller movement is of the variable speed type and can be furnished for either 110 or 220 volts, a. c. or d. c. power circuit. The welding roller bearing and the lower horn are water cooled.

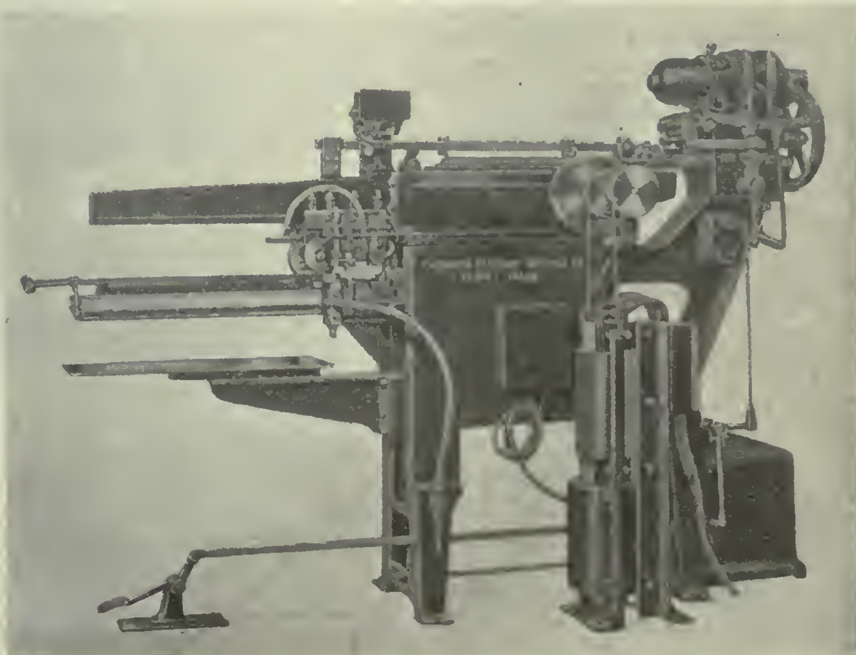
NEW MOTOR HEAD STOCK SPEED LATHE

The accompanying illustration shows a new four-speed alternating current motor headstock speed lathe, manufactured by the Oliver Machinery Co., Grand Rapids, Mich. This lathe is designed to operate on three phase two-twenty volt current.

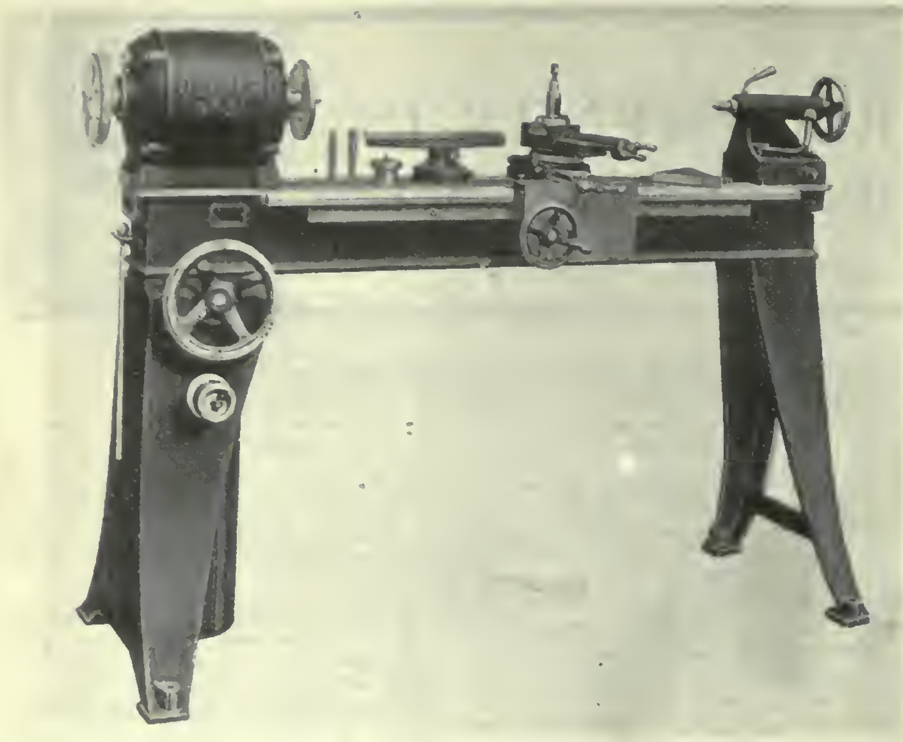
The lathe is shown with hand feeding carriage and compound swivel rest and may be furnished with plain bed in four or five foot lengths so as to turn twenty-four or thirty-six inches between centers respectively. The swing of this lathe is the same as that of the other motor head speed lathes manufactured by this company.

The motor headstock and ball bearings are totally enclosed in dustproof housings, thus being entirely dust and dirt proof. The rear end is fitted with a new feature, a combined hand wheel and faceplate. The edge is rounded off exactly like a handwheel and the inside face is curved in so as to give all the advantages of a handwheel while forming a perfect faceplate for rear end turning.

The controller of the motor has much the same shape as the standard street car controller but of course is much smaller in size and is mounted inside the left hand leg. This controller is operated by the hand wheel shown and this handwheel is marked with the various speeds possible, off, 570, 1,140, 1,725 and 3,450 revs. per min. Whenever any one of these marks is at the top the motor operates as indicated by the mark and the mechanism is arranged so as to prevent the operation of the controller in the wrong direction.



ELECTRIC WELDING MACHINE



MOTOR HEAD-STOCK SPEED LATHE.

ELECTRIC CENTRIFUGAL AUTOMATIC BOILER FEED PUMPS AND RECEIVERS

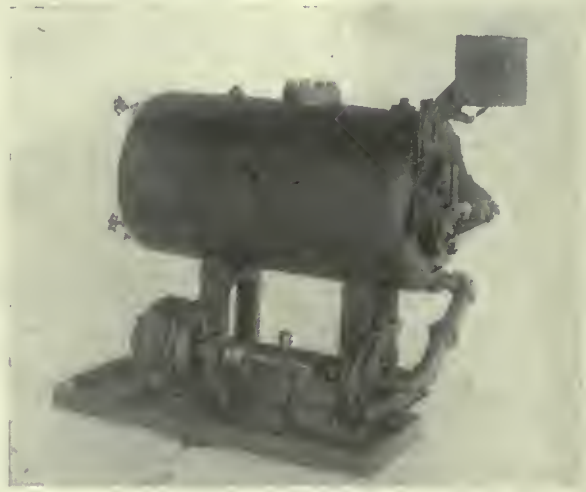
By F. C. P.

THE accompanying illustration shows a new electric centrifugal automatic boiler pump and receiver of particular use where it is not practical to operate a steam pump on account of low steam pressure carried, and where electric motor-driven centrifugal pump and receiver may be used to advantage. With this device the water of condensation flows by gravity into the receiver tank. As it accumulates, a copper ball float raises the control apparatus at end of tank which closes the circuit and automatically starts the motor. When the water is pumped out of the tank the float, of course, drops, thereby shutting off the current to the motor and stopping the pump.

As will be noted from the illustration, the pump and tank are mounted on a heavy cast iron drip pan, which catches the drips from the entire unit. The tank is made of close-grained cast iron, and is firmly mounted on two iron legs. The pump casing is of the overhanging type, and may be turned so that the discharge may be taken in any direction desired. The impeller is machined all over, and as the clearance between the heads and impeller is reduced to a minimum, the centrifugal pump is very efficient in operation. The pump and motor are connected by a flexible coupling and the bearing is babbitted and equipped with thrust collar.

The regulations relative to the use of starters or accelerating switches vary in different localities. Ordinary starters are not required on motors of 3-h.p. or less and compound wound motors are used for this service. When installing, the pump is placed as near to the boiler as possible and a globe valve as well as a check valve is placed in the discharge line to the boiler, the globe valve being placed between the check and the boiler.

This electric pump of the largest capacity for a radiation surface of 12,000 to 30,000 square feet delivers 60 gallons per minute, the maximum delivery pressure being 25 lbs. or 58 feet, the minimum speed being 1,905 revolutions and the maximum speed 3,600 revs. per minute. The 2½ h.p. motor weighs 1,200 lbs., and the receiver measures 20 inches in width and has a length of 41 inches. The motor is directly coupled to the pump.



BOILER FEED PUMP AND RECEIVER.

STRIKING HARD SPOTS SPOILS THE HOB

Not an Unusual Thing to Have a Tap Spoiled by a Slight Flaw

In threading the nose of the various types of shells the operation is generally performed in one of two ways, either by means of a collapsible tap or by using a solid hob. Many manufacturers are accomplishing this detail in the former manner, while others are holding to that of cutting the thread by the milling process.

Owing to the nature of the work it is necessary that considerable care be exercised to minimize the destruction of the taps or hobs utilized for this purpose. It is not alone in the actual threading of the nose that care should be taken but in the various details that are contingent to the heating and closing of the nose. Frequently during this operation, either through carelessness or neglect on the part of the furnace or press operators, conditions may arise that will result in the formation of local hard spots in the metal at the nose of the shell. In many instances these spots are unnoticeable until the thread is being cut and the hard spot will invariably have the effect of partially or wholly destroying the cutting qualities of the tap or hob. If a tap is used the possibility would be to wear away the forward or cutting teeth, the sizing of the thread being accomplished by the following teeth. The operation of a hob, however, is entirely different than that of the tap, inasmuch as every portion of the cutting length is responsible for producing the thread in the shell nose. The presence of a particularly hard spot very often results in the total destruction of the hob, as the speed of the latter does not permit of removing the same from the cut until the damage has been done. Just recently the writer was shown a British 14-thread hob that had been completely destroyed by one of these hard spotted shells. It appears that when the hob was being forced to its cutting depth the points of several teeth for a width of about one-half inch were broken off and imbedded in the metal of the shell, the obvious result being the destruction of the other teeth on the hob in the path of those first broken off. In the case of a tap the front teeth may be reground and serve until replaced with a new tap, but when a hob meets with such disaster the only remedy is to replace it immediately with a new hob.—J. H. R.

The Power Users Should Look Ahead Right Now

Ontario is Using and Calling For More Power Than is Available —The Steam Plant Should be Utilized For Power Where Steam is Necessary For Heating Purposes—Time to Take the Warning

By F. W. SUTHERLAND, Assoc. Editor Canadian Machinery.

RECENT reports concerning the available coal supply granted the Ontario district by the U.S. Fuel Administration point very strongly to the necessity for economy in coal consumption during the coming winter. It is extremely probable that only about 70 per cent. of last winter's supply will be available.

This will probably work greatly to the disadvantage of the manufacturer employed on the so-called non-essential industries and very little relief can be expected from Hydro-electric developments until the new year when the new penstock and turbines will be available at the Ontario Power Company's plant for the furnishing of about 50,000 additional horse-power.

The extent to which the consumption of electricity has increased may be judged from the demands made upon the Niagara system of the Hydro-Electric Power Commission. The Toronto system in November, 1917, had over 50.000 customers and a connected load of about 75,000 horsepower for which at that time only about 50 000 horsepower was available. The result of this power scarcity last winter was seen in the curtailment of street and storelighting and in the cutting off of feeders serving a purely residential load at times during the day when the peak load came on.

It it idle to expect any improvement in this condition during the coming winter, at least until new supplies of power are made available and in the distribution of the available power, munition plants, in the wider application of the term, must necessarily come first. Undoubtedly much power and light are absolutely wasted and the time is probably close at hand when drastic measures must be taken to curtail the use of electric energy now employed on luxuries and thus make it available for necessary purposes.

Niagara and the Munitions Industries

The diverse and extensive demands upon manufacturers for materials of war and of the necessity for ample supplies of power consequent upon this demand are sometimes overlooked. Of the immense amount of power generated in the Niagara district the greater part is used in manufacturing of munitions of war such as abrasives, aluminum, chemicals, steel and other electro-chemical and metallurgical products. The Niagara district supplies the bulk of the ferro-alloys, all-essential in the steel industry. Abrasives, cyanides, aluminum, carbon, electrodes, and many other products are urgently needed in the war game.

The average individual has little or no idea of the important part played by abrasives, to use the term in its widest sense. If asked concerning his knowledge of the subject, he would undoubtedly reply that it extended to the sharpening of the various cutting instruments with which he was familiar and that he possessed a vague idea that sometimes "grinding wheels were used in machine shops for various kinds of rough work.

So far is this from the truth that it need only be mentioned that modern grinding methods alone make possible the standardization and quantity production of munitions by means of the close limits in workmanship made available by their use. Not only are abrasives necessary in the making of munitions but their use is all essential in the manufacture of machine tools, textile machinery and other means whereby everything the soldier uses and wears is made. It is interesting to note that the artificial manufacture of corundum being carried on in the Niagara district has a direct and important bearing on the production of ferro-alloys, ferro-silicon being produced in quantities as a necessary part of the process.

1. One means whereby the power shortage may be somewhat minimized is by the use of steam power wherever available. This recommendation may seem somewhat futile in the face of the scarcity of coal but much can be done in the efficient utilization of the available supply. It is a notorious fact that central station energy can often be sold for a lower figure than that for which power can be generated in the isolated fact. This in a large measure is due solely to the inefficient operation of the smaller plant and when steam is used for heating or industrial processes it is not only cheaper to generate power from it and to use the exhaust steam, but it is a serious waste of the country's resources not to take advantage of this source of power. While the most efficient prime mover is only able to extract a small percentage of the total heat put into the working fluid, steam, when this power can be generated at a cost consisting of capital charges and maintainance only and the remaining heat utilized for industrial heating and other uses, the steam engine or turbine becomes a good investment and a direct aid to conservation.

Aside from the above means of deriving energy the more efficient operation of every steam plant or other means of using fuel for industrial uses or heating is a matter of some concern. The average power or industrial heating plant is after all no more economical than that notorious fuel consumer, the house furnace, and better operation ought to be rigorously enforced. It is an easy and not very costly thing to provide indicators, gas analysis apparatus and other means of testing fuel consumption and the benefits derived from their use more than balance the outlay involved. The elimination of soot and scale on boiler surfaces and proper methods of firing are also steps in the right direction.

2. The curtailment of power used for street and ornamental lighting has been of much benefit and the continuation of this means of saving energy may be expected for some time to come. It is probable that in addition further restrictions will be enforced tending to the limitation of power used in industries not essential to the winning of the war. This if put into effect would have a two-fold advantage in that it would also divert a certain amount of labor into very desirable channels.

3. The more efficient utilization of the capacity of existing plants in the Niagara district has been gone into rather carefully and much is being done along this line. Water is being used up to the limit fixed by international treaty and the excess capacity of the plants is thus being utilized. The new Chippawa project which the Hydro-Electric Commission has started will, with the more efficient utilization of the water, due to the greater head, provide about 200,000 horse-power, but this will not be available for about two to three years. The size of the individual units (50,000 horse-power) is larger than in any other hydraulic development in the world. While this plant is under construction the commission are moving as rapidly as possible to have additional equipment installed so as to have available in about ten months an additional 50,000 horse-power from the plant of the Ontario Power Company.

The situation as at present existing must necessarily work to the disadvantage of the places somewhat remote from the source at which power is generated and the recent action of the National Abrasives Company in moving to the Falls is explained when the engineering requirements in connection with the transmission of power are understood. Line and other transmission losses in this case amounting to possibly 10 per cent. are obviated and an equal amount of power saved for other essential industries.

Sane Action On Housing Problem

IN another section of this issue is an article dealing with the housing problem as it has been dealt with by a large manufacturing firm in United States. Anything that will act as a fingerpost to the solution of this problem is readable now.

Strange that people haven't gone at the thing long ago and cleaned up on it. It has been tinkered with and booted around the premises until the name tastes sour, and smacks of some money-grabbing scheme that aims to get a set of hooks on to the pay envelope of the man in the shop.

But there is a better setting now. The whole business is being taken up by men who don't care a hoot whether they make a cent or not, as long as a large number of people have decent homes in which to live and bring up their families.

Rightly or wrongly there has been a fair-sized touch of suspicion attached to housing "schemes" in the past. The "schemes" suggested the "schemers," and there lay the trouble. The man who was tempted to go in had a quick vision of the bailiff and a forced sale of his few sticks of furniture when his payments were not made. He had heard of others who paid high rates of interest, and who made life miserable for themselves and their families by camping nightly in front of the calendar watching for the day of interest to come due, and wondering how under the sun he could scrape up enough by then to meet the payment. And when the payment was met, the free-for-all started again in anticipation of the next date.

As long as the principal thing in a housing scheme is the making of money for some schemer behind the scene, just that long will the thing be the miserable failure it deserves to be.

A goodly number of Canadian cities are coming to their senses in this regard. They are fast moving away from that form of insanity that found outlet in all the fool community "boosting" stunts that some overly paid publicity man could name in order to justify the existence of his office. And it's high time that there was a period of calm deliberate consideration of the things that will in reality boost any city or town.

If a city aims at commercial supremacy it has to have a good labor market. What makes a good labor market? Let the cities sit down quietly and think the matter over, and they will find several things, some of them being:—

(1) A well-housed lot of people, owning their own homes, or renting them at prices within their means.

(2) A tax-rate that does not make it desirable or imperative for a man to keep his home in the shack class.

(3) Some provision for the man who honestly desires a little wholesome advice and assistance in regard to acquiring a home for himself.

(4) The providing of the assistance in such a way that the man seeking it is not tying a millstone around his neck, and the giving of a fair chance to recover what he has put in the property in case he is not able to keep up payments.

It is not necessary, when housing schemes are considered, to open up a new tract of land. That plan often kills the scheme before it gets a chance to sprout and grow. The opening of new districts means putting a large amount of money into utility services, such as water lines, gas and sewer pipes, electric light services, the building of roads and sidewalks. Bulk buying of vacant property, in some cases at expropriation prices, is the solution in some places. It is sometimes necessary and even desirable to use pressure to make certain residents see that it is not desirable or possible that they should continue to allow thistles and burdocks to grow on vacant land in the hope that some other person's enterprise may make it worth more money.

Manufacturers are considering housing problems now as part of the investment they make in their plant. They have all been through the mill and they have all heard good mechanics say, "I can't stay in your plant because I can't get a decent place to live." And the manufacturer has known beyond the chance of an argument that the man was telling the truth, and known also that his organization would be the poorer because that class of mechanic had the big obstacle of no houses in the way of entering and staying in his employ.

It's a hopeful sort of a sign that housing is being seriously considered now apart from those interested in the securing of six and seven per cent. on a first mortgage. A mortgage should be turned into the best friend the mechanic can have, rather than transformed into a horrible club and suspended over his head. These things are possible, and we believe that it will be amply demonstrated in a short time that they are.

Letting Trade Routes Slide

SIR JOSEPH MACLAY, controller of shipping in Britain, has brought forward a fact that should not be passed lightly over. Speaking of the fact that Britain has provided the protection for U.S. forces crossing the Atlantic, he said:—

"But I might add, since the fact may not be well known, that we are only able to face these new responsibilities by sacrificing for the time not only British, but Imperial interests. Ships, which under normal circumstances are engaged in the trades between the British Isles and the Far East, Australasia, and India, have had to be withdrawn from service, and we have been compelled to sacrifice to a large extent communication between the Mother Country and the Dominions and the Southern Seas."

This statement was not made as a complaint; Sir Joseph was not urging that Britain was making too great sacrifices—rather it was simply a statement of absolute fact with which the people should be made acquainted.

Britain is letting her foreign trade slide; she is taking off boat after boat from trade routes that have been, and will be, matters of commercial life and death to her. The Island country is sparing nothing—Britain is in it to the neck, and will stay in it to the neck till it's all over and cleared up.

At the same time it is well to look forward to the day when trade routes will have to be won back, and when commerce and industry will have to ply again. War not only breaks down the enemy, but it weakens the people waging it.

COSTS NOTHING TO HELP THE OTHER CHAP.

Charles Thurston Ironed Out a Little Matter That Had His Friends "Stumped"

CHARLES THURSTON, answering his telephone one Sunday morning, recognized the voice as that of a man whose real name is not Bill. "Sure," he said "come right on over. If I can help you, Bill, I'll be glad to."

Half an hour later Bill arrived. To Thurston he mentioned his new job and, somewhat diffidently, broached the matter troubling him.

"I never had much schooling," he said. "And now, not knowing decimals, I'm kind of stumped."

"How's that?" Thurston asked.

"Well, it's this," Bill said, producing a micrometer; "I don't know how to use this, and I got to use it."

CHARLES THURSTON

"That's easy," Thurston told him. "But who put decimals into your head?"

Bill mentioned the name of a mechanical engineer to whom he had appealed for help some time before.

"And he shot clean over your head," Thurston said, understandingly. "Just you remember this, Bill," he went on. "This 'mic' is for making measurements to one-thousandth of an inch. Instead of the inch being split into halves, quarters, eighths, and so on, it is split into one thousand equal parts. Now if there are a thousand of these parts in one inch, there are exactly half as many in half an inch; exactly a quarter as many in a quarter inch."

Bill readily caught on, and after a little further explanation in words and figures understandable to him, he gratefully thanked Thurston for showing him how to use the micrometer.

CANADIAN MACHINERY relates the foregoing incident more for what it illustrates than for any virtue in itself.

In the case of Bill, it serves to show a need for a little further practical education that could easily and quickly be acquired. Moreover, it raises the question: How many machinists at some time or other find themselves, as Bill said, "stumped?" How many bump into the thing they don't know and never get beyond it simply because they dislike to ask a fellow workman how it's done? You can be pretty sure on one thing; they are men who do not read any technical paper and who do not know that good technical papers are pleased to give easily understood answers to men's work problems.

In the case of Charles Thurston, the incident serves to show the universal willingness to help others of men who have worked hard and studied hard to push themselves upward. Indeed, their further success very much depends on willingness and ability to instruct men in their charge.

Mr. Thurston started as a lathe hand in the machine shop of the Polson Iron Works, Toronto, twelve years ago. He was soon promoted to assistant foreman, and for the last five years he has been general foreman of the shop and in charge of installations of all ship machinery.

"I got ahead by doing my very best by the firm," he told CANADIAN MACHINERY. "Before coming here I was leading man in the Canada Foundry Company's plant for one year and seven months. Prior to that I was the Rathburn Company's leading man at Deseronto for six years. For three years I had charge of all the machinery in the Charles Thompson paper mills—known as the Napanee Mills—at Strathcona. I resided in Rochester, N.Y., for five years, working for the Shipman Engine Company; W. P. Davis, tool makers; and the Knolton Beach Company, paper box machinery manufacturers. About 1890 I returned to the little town of Glenora, near Belleville and again tried my hand at work to which I was apprenticed when a lad of fourteen. J. C. Wilson owned the shop, and we made small turbine water wheels. I was there eleven years altogether."

JUST imagine the reception one of those little German bands would get in this musical zone just now.

* * *

ONE way of describing an alternating current is by pointing to a fat man fussing at 95 in the shade about his coal bin being empty.

* * *

A MAN who sits in front of an electric fan and stews about the heat should take a 12-hour shift at a mill rolling plates or sheets. After that his 90 degrees' office would seem like a day late in the fall.

* * *

THE Liverpool *Journal of Commerce*, speaking of British methods, refers to "the stupid bungling and the 'village pump' official methods, which for the last three years have prevailed in the official policy of dealing with our shipping and shipbuilding." Such an outburst in this land would surely cause the censors to reach for the muzzle loaders and an extra big charge of rock salt.

We're Stayin' On The Job This Year

Steel production is keeping up remarkably well on war work despite the hot weather. —News item.

OH, rollin' steel's a job, my boy, for days what's cool and fine, and when the weather man ain't stokin' nor workin' overtime; when sweat ain't drippin' from your beak nor tricklin' in a stream, and runnin' down in pints and quarts and coasting on your bean.

On days what's hot it's easy work to let the whistle blow, and let them work and sweat what will, and let them come and go. It's easy then to shirk the job, to let things drift along, and make yourself believe such stuff ain't slacker type nor wrong.

But things is diff'rent now, me boy, we've somethin' more to do than go and look for shady spots and skies what's clear and blue.

In the good old days when loafin' off was quite the proper thing, we didn't have no Kaiser a-campin' in the ring, and tryin' to turn things up on edge and rule the universe, and get us all in shape to live beneath the German curse.

And we didn't have no Western front, no storm-rent bloody skies, no cry goin' up to us at home, "For God sake, send supplies!"

We didn't have no brothers then, no sons across the sea, a-facin' death and shot and shell instead of you and me—no boys from home in khaki clad had marched away to fight, no mothers' hearts were rent and sore, no long and sleepless night.

We didn't have no German planes a-droppin' bombs and things, until the air is pierced with groans, until it fairly rings with cries of children and of babes, with groans of crippled folk, who've had a glimpse of hell on earth beneath the German yoke.

So we're stickin' on the job, me boy, when days are hot as fire, and we're workin' for a greater thing than just our job and hire.

We're workin' for our sons, me boy, we're workin' for our home, we're workin' for them lads of ours in yonder shell-swept zone—we're workin' for them brave chaps there, our own folk and our kin, to keep this little world of ours from bowin' to Berlin.—Ark.

MARKET DEVELOPMENTS

Allies Don't Need Barb Wire for Defences Now

Interesting Side Light on War Situation—Firms Handling War Contracts Having Trouble in Securing Deliveries—Progress Has Been Made in Settling Prices of Some Staples

THERE seems to be small chance for Canadian business talking of expansion, if such expansion depends in the first place upon their chances of going into the steel markets for increased supplies. The fact is that there is no chance of increased steel supplies coming to Canada. Taking that as the starting point, the only thing is to make the available supplies go to the points where the most essential work is being carried on from the viewpoint of the war officials. It has been a hard matter for the Canadian allotment of steel to be sustained week by week. In fact there have been times when there has been a falling off.

Conferences have been held between jobbers and the War Trade Board and in many staple lines prices are now recognized as standard, but there are a few lines that are not settled, the authorities holding that the warehousemen were doing business at too high a figure. The latter base their contention, in part at least, on the fact that their export trade is largely gone for the present, and that with this revenue cut off their overhead charges have not decreased at all.

The big problem for dealers in machine tools just now is not the securing of new business, but the filling of orders they already have on their books, and partial delivery of which has been made in a good many cases.

The situation in this regard is not all that could be desired by any means. This is not common to this country, but practically all over United States the same story is heard. There are going to be some delays in deliveries on new shell contracts. Contractors do not favor the plan of going ahead and working on one or two operations in a shell plant, waiting for the rest of the work to be done when the machines arrive. The shop gets clogged at this one stage. The only way is to get a steady flow through the shop on all operations, and the non-delivery of certain machines is delaying this.

An interesting little sidelight is brought to notice in a despatch from one of the big steel centres of United States. It announces that the call for barb-wire for defensive purposes is falling off tremendously among the Allied forces since Marshal Foch took the offensive on the West. Mills that were working on this are getting instructions to turn more to other war lines.

NOT MUCH BARB WIRE NEEDED SINCE FOCH TOOK THE OFFENSIVE

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Aug. 28.—Testimony given last week by departmental representatives to Congressional committees considering "manpower" or draft legislation, that the war can be completely won before the end of next year by America's whole force being put into the work, furnished the steel industry no new view of the situation. For some time past the preponderating view in the steel trade has been that the war would be won before the end of next year. This view obtained despite the fact that the steel trade well knew that the war machine is preparing for five years of war. Whether in holding this view the steel men were depending upon their judgment, based upon the vast weight of steel that is being thrown, and is to be thrown, into the war, or merely reflected the assurance given them by the military authorities, with whom they are in constant and close contact, is not known.

Secrecy in the Work

There is nothing that could pass muster as representing even a partial inventory of the applications of steel in the war, but the fact should always be borne in mind that this absence of detailed information is due solely to the secrecy imposed. The information exists, but only on the hands of those whose duty it is to know. It is never allowed to pass farther along the line than is necessary. One man, for instance, a prominent steel company official, distributes all the orders for shell steel. He knows to a ton how much has been furnished and how much is on order, and he knows approximately how much additional is to be called for in the near future. The mills with which he places orders, however, do not have the total figures either exactly or approximately. A committee of three distributes the sheet orders, though the chairman is chiefly responsible, and thus it is all along the line. These are men in the steel trade. They do not know, except approximately, what is coming in the way of requirements. In some commodities they are better informed than is the case in others, because some commodities are required regularly for continuous work, as in shell making, while in other commodities, as in structural shapes, the needs vary according to the different projects taken up. The War Industries Board, on the other hand, has much advance information of requirements.

Requirements Increasing

What is to be observed at the present moment is that the steel requirements for the war are increasing, as to the total. Few military purposes for which steel is required have been entirely fulfilled. Even the cantonments, for the preliminary training of men, while completed long ago according to the original plans, are now in some cases being enlarged. Shipbuilding grows constantly, of course. Many of the shipways are not completed yet. The furnishing of equipment for ships must increase greatly, as many ships recently launched are awaiting equipment. This includes engines, boilers and a thousand and one minor items. Shell manufacturing is increasing. Railroad operations in France contemplate a larger and larger scale. In addition to many small cars ordered in the past two or three months for the A. E. F. orders for 20,000 additional cars have just been approved and the distribution is now being made, while rumor has it that 30,000 or 40,000 more cars may be ordered in the near future as part of this program. For the rebuilding and enlarging of the two railroads across France allotted to the A. E. F. 150,000 tons of rails were ordered about a year ago. Other and smaller orders followed, and in the past few weeks 200,000 tons additional have been placed. Conferences as to price did not reach a conclusion and the orders are being filled subject to a price to be determined later. Including the light rails required for the narrow gauge trench railways the orders for the A. E. F. to date doubtless total more than 500,000 gross tons, this being entirely apart from rails furnished the French authorities

This is Splendid

Through the change in the character of the military operations the demands for barb wire have been lighter in recent months, and Marshall Foch's principle of keeping always on the go seems to preclude any large demand. It may be remarked parenthetically, however, that so precisely does the machinery for employing the steel industry for war purposes work that this does not make wire more plentiful for civilian use, since immediately there is provided an offset. Orders for a large tonnage of 82 mm. rounds for France have just been distributed, and a large part of the business has been given to wire plants, whereby such plants will change rolls on their small billet mills, to roll the rounds, and the small billets will no longer be available for the rod mills, so that wire production, lately no more than 60 per cent. of capacity, will be reduced further. The demands for pipe for war purposes are very heavy, much greater than was expected. Last year, when a very large order for large pipe for the British operations in Mesopotamia was completed, it was thought that not much more such pipe would be required, but large pipe is now being used by the A. E. F. on an important scale, while there is heavy demand for shipbuilding and for the equipping of various new war plants.

In Total Figures

Thus while available information is quite fragmentary and very far removed from being complete, it affords entirely satisfactory grounds for viewing with profound respect the current estimates of the War Industries Board that 20,000,000 to 22,000,000 net tons of finished rolled steel is required for the present half year, and not less than 20,000,000 tons for the first half of next year. The estimates, of course, include some allowances, perhaps rather meager, for the commercial industries at home that must be maintained to keep up the country's war efficiency.

POINTS IN WEEK'S MARKETING NOTES

Production at United States mills has been showing a marked improvement in the last few days.

—

Shipments to jobbers of finished steel are much lighter than for some time past, and it looks as though they would be cut down still more.

—

Information from big steel centres of United States says the belief is firmly held that the war will be won by the Allies before the end of 1919. Whether this is so or not, all business there touched by the war is being planned on five years of war.

—

The demand for barb wire for defensive purposes has fallen off in United States mills since Foch took and maintained the offensive.

—

Wire manufacturers in United States have been ordered by the government to turn over to the making of shell bars, large orders of which are for shipment to France.

—

Canadian customers having occasion to enter the steel market at present are finding that they have little chance unless their claims are particularly urgent.

—

New lists out on wrought iron pipes place the prices quoted at a higher figure.

Production

Production has been somewhat heavier in the past ten days, through a partial recovery from the backset given by the extremely hot weather of the first fortnight in August, but the month as a whole will probably show smaller production than July. September, however, will probably see the restoration of the June rate or even a higher rate. There is more dissatisfaction with blast furnace performance. as the output is out of line with the large number of furnaces in blast. Questions of coke supply, coke quality and labor performance are being studied still more carefully. While new construction has been considered, it is held full performance of existing manufacturing facilities must first be attained. It may still be estimated that the output of finished rolled steel in the present half year should be fully 18,000,000 net tons.

Distribution to Jobbers

Jobbers are receiving even lighter shipments of finished steel than was expected as a result of the July orders relating to jobbers, which provide a B-4 priority rating, first for August shipments to an amount equal to one-sixth the tonnage received during the first half of the year, and then for subsequent months an amount equal to the tonnage distributed by jobbers the preceding month against priorities and the preference list. The jobbers have received scarcely any merchant steel bars or sheets, and their receipts of standard steel pipe and of wire products have been less than expected. This exemplifies the shortage of steel, since B-4 is a high degree of precedence. It yields to most of the priorities, but comes before the entire preference list.

BIG CALL NOW FOR SHELL STEEL BARS

U. S. Government Order Wire Drawers to Turn Capacity Now on This Material

Special to CANADIAN MACHINERY.

NEW YORK, August 29th.—Wire manufacturers have been called upon by the Government to produce shell steel bars in large tonnages. It will be recalled that a few months ago the wire drawers were instructed to cut their output 40 per cent. so that the crude steel they were making could be sent to other plants for the manufacture of ordnance and projectiles. The rail mills were largely utilized to roll shell steel bars.

Now, the pressing demand from domestic railroads makes it imperative that some of the rail mills, at least, be released to roll standard section rails. In this emergency the wire manufacturers were selected by the Government to render assistance so that there should be no decrease in the supply of shell steel to be sent abroad. For several weeks the Donora plant of the American Steel & Wire Co. has been adapting its machinery to roll shell bars and in the past ten days it has installed tables for this purpose. The first order given to the Donora mill is for 20,000 82 mm. rounds for shells to be exported to France; shipments begin this month.

Want More Shell Brass

Other wire manufacturers also have received similar orders from the Government so that 50,000 tons of rounds will be shipped to France this month. It is understood that orders for at least 100,000 tons of shell bars a month will be rolled by wire manufacturers. This is about one-fifth of the monthly tonnage required by the Government for domestic projectile makers and for export to the Allies.

The American Steel & Wire Co. has capacity to produce 200,000 tons of wire products a month but because of the shortage of wire steel its output was cut down to about 120,000 tons two months ago. If the 20.000 tons of shells which it must now roll for the Government are deducted from the tonnage available for conversion into wire products, its regular customers will be compelled to further curtail operations as only 100.000 tons a month will be available; that is, the largest wire drawers are now operating on 50 per cent. capacity. Large independent wire makers have also been obliged to cut down production. The Pittsburgh Steel & Wire Co. is now operating 50 per cent. capacity and the Jones & Laughlin Steel Co.

only 40 per cent. of their wire capacity.

To Be Sent to France

Orders for 21,000 tons of plain wire and for 2,600 tons of wire rods are now being distributed by the sub-committee of the Iron & Steel Institute for export to France in September-October-November. Allocations of 100,000 kegs of eight and tenpenny wire nails are also being made for army camps at home and for additional construction in France.

The War Industries Board has determined after conference with the Steel Committee of the Iron and Steel Institute to give preference of steel shipments, temporarily, to the railroads and to manufacturers of railroad equipment. Motive power, cars, rails, and other equipment must be furnished domestic railroads speedily to prevent a recurrence of the severe freight congestion that unsettled industry last winter. Railroad equipment is also urgently needed by the American expeditionary force in France and there are pressing demands from Italy and Japan.

Railroads in the Central West have finally succeeded in placing contracts for a large number of machine tools. The Monon at last has distributed orders on their list put out last May. The Rock-Island, Illinois Central and the St. Paul have ordered a number of lathes and boring mills and the Santa Fe is about to close on the list put out ten days ago.

The Foreign Trade

The Japanese Government is enquiring in the Cincinnati market for 100 24-inch lathes for prompt shipment and Japanese exporters are inquiring for a large number of portable electric drilling machines. The Tata Iron & Steel Co., Sakchi, India, has purchased eight magnets from the Electric Controlling & Manufacturing Co. The Tacony Ordnance Corporation is buying large boring and turning lathes for the manufacture of guns. There is great need of marine engines, boilers and other equipment and the Emergency Fleet Corporation is now concentrating efforts to secure such machinery.

WANTS TO HANDLE CANADIAN OR AMERICAN BUSINESS IN FRANCE

CANADIAN MACHINERY is in receipt of the following letter from M. Lacombe and A. Blachere, of Lyons, France. This company is open to do business with Canadian or American firms.

The letter translated follows:

Lyon, July 22, 1918.

We have been receiving your journal for some time and are greatly interested in it. Could we enter into business relations with some of the firms who advertise in it?

The firms which are of especial interest to us are those making screws (bits, augurs), raising or hoisting tackle and gear, conveying machinery, industrial oils and greases, ball bearings, automobile accessories, lifting jacks, etc.

We should like to become acquainted with a firm who on satisfying themselves with the references we would supply would treat us as their depository agents in France.

Correspondence would have to be in French. Such a firm might be either Canadian or U.S.

NEED GOOD REASON FOR BUYING STEEL

Canadian Trade Finding the War Pressure Becoming Harder All the Time

TORONTO. — Canadian customers have to show remarkably good reasons for going into the steel market now. This has been the case more or less for the past six or eight months, but the coming of each week brings a more pronounced change in the situation, and all the changes move in the same groove. As a matter of fact industries in Canada that have occasion to buy steel are up against more or less of a stone wall. There is a certain tonnage allotted to this country each week, or month, by the War Industries Board at Washington, and that is all that can be secured. This of course refers to imports, and not to steel produced in Canada, but it is on imports that we are largely dependent. So it is a case of making the material available go around rather than striving to get concerns to use more.

The licenses and priority orders that the mills require automatically expire if the obligations have not been met by the mills on the date mentioned in the papers. There is considerable confusion at times in connection with getting renewal privileges for these.

The demand for war machinery is quieter this week. In fact the big thing in the hands of the machine tool-dealers is the securing of the machines to fill contracts that have been on their books for some time.

Scrap Prices Firm

No changes are noticed in the scrap values this week. It might be imagined that there would be a lot of scrap in the way of turnings from shell plants because the volume of material going through these plants is very large at this moment. However, it does not reach the scrap metal trade, its disposition being arranged beforehand by the War Board authorities. Information received from outside points shows that there is a decided shortage in many foundry yards, and there is nothing in sight in the trade that is going to relieve it.

American points state that there is difficulty in securing transportation even when a lot of scrap is found, the carriers claiming that they are overloaded now with business that they consider to be more pressing.

Settled Price Matters

Through conferences with dealers the matter of prices has been settled in some of the principal lines. The biggest article in volume now is plate for ship work, and the Government recognize 10c per pound for this. Dealers are quite frank in advising the trade that it is useless to send in orders unless they are absolutely certain the work is of the most vital importance, and urgent enough to cause the War Board to put a very high rating on it.

As a matter of fact in the last eight weeks instead of getting 8,000 tons of plate this country has received about 5,000 tons, and working from this, it is easy to see that there is absolutely no chance at all for the man who wants steel, especially in the shape of plate, for anything but the most urgent purpose. There was a supposition some months ago that three months of concentration on war work would pile up such a heap of material that the commercial interests would be well treated at the expiration of that period. Whenever it looks at all hopeful for this coming true the war appetite doubles up, and the commercial chances go in a heap, and they are right now in a heap with poor chances of getting straightened out.

The prices on boiler tubes, it is understood, are somewhat of an open question, the War Board holding for a lower figure than asked at the moment by the warehouses.

The Matter of Ratings

The mills are in better shape than the customers in the matter of priorities. In case a mill accepts an order to deliver on a certain date their obligation for the work ceases when that date arrives and the order has not been rolled. On the other hand it is up to the dealer to apply to Washington to have his priority and license renewed to protect his business. There has been some confusion in regard to the working of this regulation.

A new list has been issued for iron pipe, an increase being noted in nearly every size. Dealers claim a shortage of skelp is responsible for the situation.

A Matter of Delivery

There is one inquiry this week regarding equipment for a shell plant but the contract in this case has not been secured yet, and the chances are that the contractor is hesitating over making promises regarding the delivery of shells. As a matter of fact there are a number of shops all over the country that are considerably embarrassed at the non-arrival of machine tools. Jobbers are having some interesting sessions explaining to the trade why deliveries are not made. This condition is not peculiar to this country, as reports from United States points indicate that much the same thing is holding up deliveries of finished shells there. Contractors hesitate to go ahead with first operations to any great extent, preferring to wait until their whole plant is in shape to get a steady and continuous flow of work through all the operations in proper sequence.

Machinery from United States points is having a hard time getting to its destination. One firm has an order six weeks on the road from Cincinnati. In this instance a customer from a point in Saskatchewan came to Toronto believing that the shipment would be here some time ahead of him. On his arrival he found that the goods he came to inspect for purchase were still on the road.

A traveller for a large American firm stated to CANADIAN MACHINERY this morning that buying of high speed steel had been carried on on an unprecedented scale during the last few weeks. Getting supplies for the Canadian buyer had been harder on this account. The American buyers had orders in very large quantities, and there had been a busy time in spots trying to keep pace with the call for hobs and reamers. In some of the work there it had been found in machining operations that the work of the forges had been rather indifferent. When the shells were put through some of the heat treating processes they had apparently been hardened to such an extent that some of the shops could hardly secure a tool point that would make a mark on them. Mechanics, this traveller stated, who had gone to United States from Canadian plants claimed that the forging that had been done to the specifications of the Imperial Munitions Board in Canada was much more uniform, and much easier to work in the machine shops. The result apparently has been that indifferent production results have been secured at some of the U. S. shops.

STOVE MANUFACTURERS HAVE BEEN GIVEN NO STANDING BY GOVERNMENT

IF one were to judge from reports of actual sales that are being made by the sales departments of iron at United States points it would appear that very little business was being done in any of the foundries. Of course quite the reverse is the case. The Government is practically handling the output of all the furnaces and the selling by them independent of Government control is being discouraged. Some of the industries of the United States that have not yet been listed are making big efforts to secure consideration at the hands of the Government but have so far met with rather indifferent success. The reports concerning the big iron situation from United States points are as follows:

Cleveland—A fair amount of selling for next year's deliveries is being done but it is all subject to Government restrictions. The new forms that are being sent out by the producers are now being distributed and it is found that they require considerable more data than has been given in the past.

Boston—The survey of the situation here would lead to the belief that there are a number of concerns all over this district who may not be able to do business in a few months because of the scarcity of iron. The stove business in particular is in danger of being considerably curtailed in this way. The latest reports state that some arrangement may be made whereby a certain number of stove concerns may be allowed to turn out material for the trade in limited quantities. No hope is held out whatever for unrestricted production.

New York—Dealers who in the past have been in the market years selling foundry iron are practically out of the way at the present time. Although many of these desire to take care of their own trade it is not possible for them to do so because Government places orders and these allocations have to be considered first. They simply keep on piling up and destroy any chance whatever of private business being considered.

Buffalo—The producers here are most swamped with orders from consumers all over the country for any grade of iron, but in almost every case the answer is the same, that the producer will do business only on allotments made by the Government.

Chicago—Contracting for pig iron for delivery during the first half of next year is in a very limited scope here at present. Only the requirements of regular customers engaged on war work are being considered and amounts are not booked over the rdinary purchases of the past.

Cincinnati—It is thought here that the production and the manufacture of automobiles will probably reduce the melt in some foundries so that they will have to seek work of the more essential nature.

St. Louis—The chances of obtaining a supply of pig iron for factories in this district that are not on war work appear to be more remote than ever. A few producers expect the belief that they may have something to sell after the first of the year, but they can promise nothing definite, and they are not willing to book any orders. Stove manufacturers and other makers of specialties outside of the war list are rapidly nearing the close of their supplies of raw material. The way in which they have gone after scrap iron has resulted in a pretty fair cleaning up of all the material suitable for their needs, and the scrap situation in the near future will not be much better than the supply of pig iron.

Philadelphia—In a good many cases here the Government allotment of foundry iron is quite up to the ability of the melters to turn it out, so in that case there is not going to be any selling done. Several of the furnaces are down for repairs on account of labor disabilities.

Pittsburgh—The return of cooler weather has not yet brought about any recoveries from the falling off in production. Stove makers are making strong efforts to secure iron, but the furnace interests are declining to ship to them until they have been given some standing by the Government.

CONDITIONS COULD HARDLY BE WORSE

Calgary Paper Prints Drab Picture of Conditions In Western Mining Town

The Calgary *Herald* is publishing reports of Bolshevist plots which contemplate interference in the mining industry of Drumheller and the *Albertan*, though careful to point out that there has been no confirmation of the reports of the *Herald's* correspondent, declares that if there is any place in Canada where Bolshevism might be expected to find a foothold, that place is Drumheller. Here is the picture of conditions at Drumheller as painted by the *Albertan*:

"Almost every condition conducive to unrest is to be found there. The conditions of labor are such that the population is largely transient; the town is new and the housing is indescribably bad; the community is poorly organized and there is an absence of any feeling of civic pride; the laws are loosely enforced and the liquor laws are not enforced at all; it is known as the freest center of illicit liquor traffic in Western Canada; it is the Mecca of bootleggers, thugs and drug fiends from all parts of the country, and there is little or no attempt either to restrain crime or to construct good social organization. A large part of the mining population is foreign, and the condition of the public mind at the present time is such that there is neither sympathy for nor understanding of these people. Almost every public policy in the last twelve months has tended to alienate, exasperate and rouse the foreign population. They have been disfranchised, suspected, and in some instances exploited; almost everything which could be done to alienate them has been done.

"The mining population of Drumheller is about 30 per cent. British and 70 per cent. foreign. Over 35 per cent. is Italian, between 15 and 20 per cent. is Austrian, Greek, Serb, Swede, negro, etc. Dangerous enemy elements are not likely to have the upper hand in such a population but the soil is such that seeds of trouble once planted, might thrive prodigiously."

The firm hand of authority is required, says the *Albertan*, not only for the suppression of inflammatory enemy propaganda, but for the enforcement of ordinary law and order. It observes that the mine operators realize some of the immediate dangers, as evidenced by plans they are now making for the improvement of housing conditions and the provision of educational facilities. The *Albertan*, however, holds that the provincial Government also should act and calls upon it, not only for the better enforcement of law, but also for the establishment in the district of a well-equipped hospital and the adoption of a suitable programme having regard to the health of the workers.

VERY KEEN DEMAND SUSTAINED FOR ALL GRADES OF SCRAP METAL

AUTHORITIES in the United States are beginning to wonder how with four million men in France they are going to double the ordnance programme. The production of pig iron is not keeping up with the excessive demands that are being made on it, and while at the moment the scrap iron situation appears a little easier the drain on this material will mean that the yards will soon again be near the stage of depletion. Detailed reports on the scrap iron situation for the week show the following:

Pittsburgh—A large number of the consumers in this district are short of old material, and they are not able to cover their requirements fully. Many of the dealers report that they are not able to get tonnages, and some yards have on hand only a small fraction of the stocks they had some months ago. There has been an increased demand for stove plate, which is being bought whenever available at the maximum price of $29. One consumer in this district recently bought up 2,000 tons of this grade for which he paid the top level.

New York—There has been a continued demand here for cast scrap during the past week, and as a result it is not very plentiful just now. At the present writing supplies of turnings and also low phosphorus scrap appear in better volume than the majority of other lines.

Cleveland—The scrap trade generally here is rather dull, as a result of the vacation season, and in nearly every case demand is nearly nominal. Stove plate and similar grades of scrap are in less demand of late, but the prices generally are holding at the old level.

Chicago—One thing that is very noticeable here is the small amount of scrap being brought out by any of the transportation companies. In fact 500 tons offered by the Chicago Great Western Railroad is the only thing available at the present time.

Cincinnati—There is a brisk demand here for almost every kind of scrap at present with the exception of stove plate. and cast iron borings. Neither of these lines are holding very firmly to old prices.

St. Louis—Although there is a very big demand here for nearly every line of scrap, there is not a very large volume of business passing. The reason for this seems to be that the yard men are holding out for very high prices which the consumers are not willing to pay. On top of this it must be noted that yard stocks here are not very heavy and the holders are not particularly anxious to part with them for fear that they cannot replace them at the old prices. The whole territory around here has been scraped pretty bare of everything that generally goes into the discard heap, and the general economy that is being practiced in almost every line has a decided tendency to cut down the amount of scrap material coming into the market.

Philadelphia—The fact of the thirty-day embargo on the shipment of turnings to brass furnaces is being watched with interest here, and the feeling is that the rolling mills will be able to buy large quantities as a result. In fact some of the mills are hoping to accumulate tonnages for future use.

Birmingham—There has been a very decided demand here for anything in the nature of heavy melting steel. One of the large home consumers was in the market here for a few days ago, offering from 50c to $1.50 per ton more for a large tonnage contract than for a few hundred tons. A decided improvement in the whole situation is looked for here.

TURNS OUT FIRST RIVETLESS SHIP

Electrical Welding Has Been Used In Putting the Plates Together

Building of a steel ship without rivets has been effected in a shipyard on the south coast of England, and its construction may mark a new era in the shipbuilding industry. A process of electrical welding was used for joining the plates, in place of the usual riveting and caulking. By means of an electric arc, the joints are submitted to intense heat, and the plates are fused together. The process is not entirely new, as auxiliary work has been done in the past by electric welding. During the last year, developments have been made which have permitted of the extension of this method in ship construction. A saving of between twenty and twenty-five per cent. is saved in both time and material, judging from experimental work done on the new vessel just launched.

The general adoption of electrical welding in shipbuilding would permit a material speeding-up of production. The electric process is particularly economical in the assembling of bulkheads, deck structures and other interior work. The United States is keeping in touch with the developments in this work in Great Britain, and arrangements are under way for the construction of several 10,000-ton standard ships by the same process. These large vessels will contain about 2½ per cent. of the number of rivets originally intended, while the British boat was absolutely rivetless.

CARGO STEAMER LAUNCHED AT VICKERS'

Marked Activity in Connection With Marine Work at Big Montreal Yards

The successful launch of the S. S. "Samnanger" took place at the works of Canadian Vickers, Limited, recently. This makes the third launch from Canadian Vickers yards since the present open season of navigation.

The dimensions of the "Samnaner," which is a 7,000 tonner, are as follows:

Length, 380 feet; breath, 49 feet; depth, 30 ft.

The "Samnanger" is a sister ship to the "Porsanger," which was recently delivered by Canadian Vickers, Limited, to Messrs. Furness, Withy & Co. of Montreal, who are acting as managers on behalf of the British Government.

It is expected that the "Samnanger" will be completed within two or three weeks.

The vessel was launched by Captain H. Jonassen, of Bergen, Norway. As in previous cases there was no ceremony.

The rapid production now going on at these works was strikingly evidenced during the launch. On the dock their latest ship, the "War Earl," was being painted after having run her steam trials last Thursday, while the sister ship, the "War Duchess," was lying in the basin with all machinery on board, getting ready for trials to take place in about two or three weeks.

There is, therefore, every indication that at the end of the present month Canadian Vickers' yard alone will have completed and handed over four 7,000-ton cargo steamers, while on the berths there will be five other vessels, several of them in an advanced stage of completion.

STEAMER WEXFORD PROBABLY LOCATED

Speculation Revived Concerning Fate of Vessel Lost in Big Storm

Goderich.—What is considered the first authentic information of the whereabouts of the steamer Wexford, lost in the great November storm of 1915, was brought to port by the captain of the steamer Mariska. On his course from Chicago to Goderich he sighted and passed within twenty feet of two spars, both at approximately the distance apart the spacing of the Wexford's spars would indicate. Both of these were seen distinctly in the fall of the water between seas, one shorter than the other, with the after spar slightly bent. His familiarity with the vessel when trading on the upper lakes strengthens his conclusion that this can be none other than the Wexford. The location is 15 miles northwest by north of Point Clark, and 16¾ miles northwest of Kincardine.

The last seen of this vessel was on the fateful Sunday when the Kaministiquia, which had left Goderich that morning, had met the Wexford about the middle of the afternoon, then on her course for Goderich. All that had previously been found was a lifeboat and several bodies which came ashore near Grand Bend, thirty miles below here. From the alleged location of the vessel it is apparent that she headed into the northerly storm, but had not made many miles before foundering. The vessel's spars now indicate that she was finally heading down the lake.

SHARP CRITICISM FOR U.S. AIR PLANTS

Senate Committee Talks Straight in Announcing Result of Investigations

Washington.—Recommending one man control of aircraft production, speeding up of production, encouragement of invention and reduction of profits on future contracts, the Senate air craft subcommittee submitted its report to the Military Affairs Committee.

The investigation disclosed a waste of money and lack of common sense policy early in the war, the committee declared. It said that while many "disappointing results" were disclosed, "much has been accomplished, and the committee is glad to report that while it believes there are many things yet to be remedied, nevertheless we are approaching a period when quantity production of planes may soon be hoped for."

Three primary causes of failure of the aircraft programme to measure up to the army's needs were set forth in the report which was read to the Senate today. They are:

1. That the airplane programme was largely placed in the control of the great automobile and other manufacturers, who were ignorant of aeronautical problems.

2. These manufacturers undertook the impossible task of creating a motor which could be adapted to all classes of flying craft. It is not too much to say that our airplane programme has been largely subordinated to the Liberty motor.

3. We failed at the beginning of the war to adopt the commonsense course of reproducing the most approved types of European machines in as great numbers as possible. This should have been carried on coincident with the production of the Liberty motor. This sound policy has very recently, but after a lamentable lapse of time, been adopted.

With the British navy in war time: Upper left hand, boat drill; upper right, fusing a shell; lower left, cutting with oxyacetylene torch; lower right, diver at work.

Strength of Materials an Interesting Study

Necessary That Mechanics Should "Know Why" and Take Nothing For Granted—A Man Who Knows Arithmetic Can go Ahead and Work Out All the Everyday Problems of the Trade

By DONALD A. HAMPSON, Assoc. Mem. Am. Soc. Mech. Eng.

THERE exists an erroneous impression that the subject of "Strength of Materials" is beyond the person of ordinary education and is very difficult at best. This belief has kept many mechanics from delving into the subject at all, believing that a long period of study of preliminaries is needed to prepare one to master the intricacies of strength of materials. As a matter of fact, any one with a good knowledge of arithmetic can follow and do all the problems encountered in everyday work. At the present time when men far past the usual studying age are having new responsibilities thrust upon them and unusual opportunities for advancement are all about, a knowledge of the theory underlying so much of construction work is of the greatest assistance.

And so it is with younger men and mechanics of all kinds. The machines they run and the materials they work—fundamental rules were the basis of the shapes and sizes; and, in repair work, an application of the same rules will tell why this part broke or that piece bent. Of course, we hear it said that "that rod ought to have been heavier to stand the strain," and "if I were making that bracket I would make it thicker in the top web," but could we tell why so much metal gives greater strength when so placed or just what size of rod is safe for a particular function and have our designs stand the scrutiny of the mechanical world, knowing our figures are correct and not based on snap judgment alone? It is very true that millions of parts are and can be designed without the application of theory; it is equally true that all major parts should be amply strong and safe—but that is no excuse for giving to them twice the weight that they need.

Two examples from the automobile manufacturing field serve as illustrations. First, the Ford car; the Ford has carried to an extreme the idea of making each part of material of the greatest strength and of scientifically distributing that material to offer the greatest strength with the least weight. Second, a New England firm that has now fallen into other hands; half a dozen fortunes were lost in the business in as many reorganizations in an effort to make and sell a car that was designed and built on "experience" without the aid of a single technically trained man, while the competing cars all had that advantage. The point we wish to make is that any person in the machine shop field can see the why and wherefore of a hundred things that he always took for granted, by a working knowledge of strength of materials, and one of the most valuable assets for promotion is an ability to cope with problems in that line.

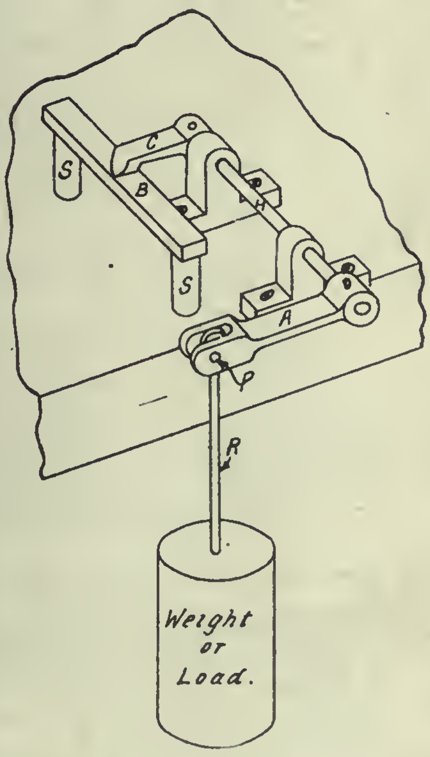

FIG. 1—DEVICE ILLUSTRATING SOME OF THE PRINCIPALS OF MECHANICS.

Experimental Model

Fig. 1 shows a device built for experimental purposes. It will be seen that the weight is suspended by the arm A and the rod R, the former pinned to the shaft H which also has an arm pinned at the far end. This arm bears on the bar B which rests on the blocks S, S standing on the bench. Any apprentice will tell you that the blocks finally transmit the effect of the weight to the bench and that if the blocks gave way the weight would drop. The same apprentice would tell you that if the blocks were of too weak material they would crush or squeeze together, that the bar B would bend if it were not stout enough, that the arm C would bend as would also the arm A, that the shaft H would twist if it were not strong enough, that the pin passing through the rod end and A would cut or shear off if it suspended too heavy a load.

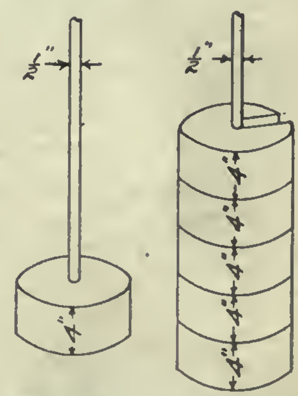

FIG. 2—THE RIGHT HAND ROD IS STRESSED TO FIVE TIMES THE LEFT.

Knowingly or not, the aforesaid apprentice has analyzed the forces and their effects in the various members of the device. Such analysis must precede most calculations in strength of materials or else the effect of the forces must be known or assumed. But in-

	Shaft H.	Torsion.	Twist.
	Bar B.	Flexure	Bend.
2	Posts S	Compression.	Squeeze Together.

TABLE I.

stead of saying that the rod would pull apart, we say that it is "stressed," and that the name of the stress is "tension." Just so with the other parts, there is a correct technical term for the lay term as applied to the stress in every part. Table 1 gives the technical term for each

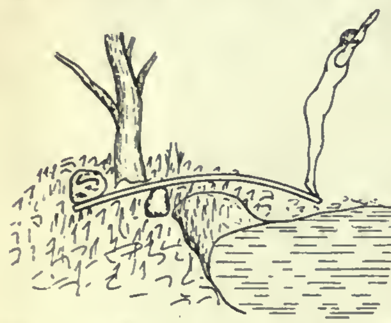

FIG. 4—STRESS IN BOARD DUE TO WEIGHT OF SWIMMER.

case and, for comparison, the lay term is added.

Loads and Stresses

In strength of materials we have to deal with the effects of weights, pressure, blows, etc., which are grouped under the term of "loads"; the term force is also used though there is a distinction which however we need not consider at the present moment. These loads, in forces, act in different ways, and, according to how they are applied to a part, tend to distort that part—that element in the part which resists the distortion is called a "stress," and the part itself is said to be stressed. Ordinarily there is no visible distortion, but the part is stressed nevertheless. In Fig. 2 one weight is suspended from the left hand rod and five from the right hand rod; both rods being of the same size, it is easily understood that the right hand rod is stressed five times as much as the other.

A stress is really an internal force resisting any change of form. A most excellent example of a stress as a force is seen in Fig. 3, the familiar spring board of the swimmer; normally straight, it bends under the swimmer's weight and the stress so set up loses no time in returning the board to original shape and incidentally giving the impetus for the dive. A body in repose usually is not stressed at all except from its own weight, as witness the spring board above which normally would extend right out straight.

In shop parlance and in conversation generally, the word "strain" is used for stress which is the correct term. If the load on a part is so great that it does not return to its original shape, the amount of the deformation would be the "strain." The correct engineering term should always be used, and as stresses are the most frequent and are a leading factor in the subject, the student ought to drop the incorrect term absolutely except when the infrequent strain is encountered.

Measuring Stresses

Stresses are measured in pounds per square inch, taking the area of the cross section for measurement. Thus in Fig. 1, if the area of the rod A is one-half square inch, and the weight is 1,000 lbs., the stress in the rod is 1,000 lbs., which is at the rate of 2,000 lbs. per sq. inch, and the latter is the value that would be used in computing or comparing with the known strength of the material in the rod. The steel in the rod has a strength of about 60,000 lbs. per sq. inch, and 60,000 and 2,000 (not 1,000) are the values used in determining the relative strength of the rod to bear the load of 1,000 lbs.

No matter what the nature of the stress—any of the five detailed in Table 1—the square inch basis is employed, and if one square inch (of area) will resist a given force then five square inches will resist five times that force if the force is applied in the same manner. If a compressive force were applied to each of the bars in Fig. 4 they would be stressed the same as would a bar of 2 square inch area.

It is a simple matter to determine the stress produced by a single force—whether it is tension or shear or torsion—acting in a machine or when the machine or structure is being designed. Though there are five of them named in Table 1 modern practice and theory reduces these to the three that are numbered, i.e., tension, compression, and shear. Torsion is considered as a shearing stress and flexure as a combination of tension and compression. A good illustration of the combination of stresses in flexure (bending) is shown by Fig. 5, A and B; the piece shown at A has a notch cut part way through each side; at B the same piece is shown bent, and, while the ends remain intact, the upper notch has closed and the lower one has opened wider proving that half of the fibers have stretched and the other half have compressed.

Some materials when stressed are very strong, while others are weak under the same kind of stress. Cast iron shows the widest difference in this respect as can be noted by referring to Table II, which shows that this metal is several times as strong in compression as in tension. Practical applications of this property are seen in countless designs—

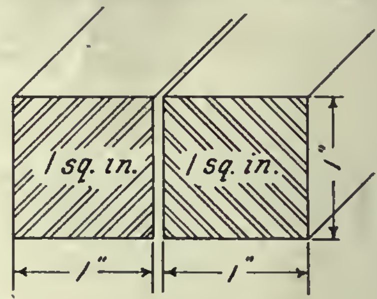

FIG. 4.

Fig. 6 is a frame for a punch with the stresses marked as they occur in working; the iron on the inside curve is in tension, "just what it should not be because there the load is greatest," you will say, and this is true, but to offset this the frame is made with a thick wide rib at the inside which adds enough metal so that the stress per square inch is within the safe limits of cast iron. The point where the stress changes from tension to compression is at the intersection of the two lines.

Fig. 7 shows the connecting rod of a steam engine. Any mechanic will tell you that this rod should be made of steel or wrought iron, never of cast iron, because cast iron would pull apart on the return stroke and wouldn't stand the jar—reference to the table again proves that cast iron is a poor material in tension. The connecting rod is an excellent example of a part that is stressed first one way and then another—compression on the forward stroke and tension on the

Cast Iron	6	20	16

TABLE III.—FACTORS OF SAFETY IN COMMON USE.

return. The table shows why steel is adapted to such uses, being practically as strong in one as the other.

Tension, Compression and Shear

Calculations for parts in tension, compression and shear are very simple. They are based entirely on the area of

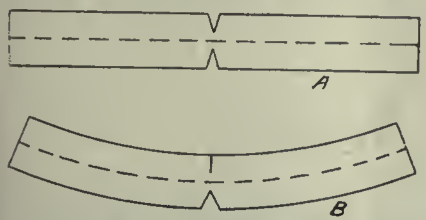

FIG. 5—SHOWING EFFECT OF LOAD IN STRESSING THE FIBRES OF A BEAM.

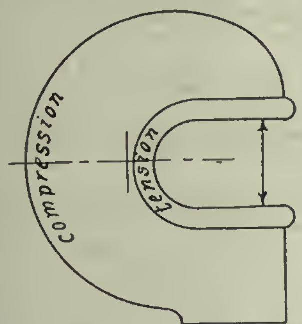

FIG. 6—FRAME FOR A PUNCH SHOWING STRESSES.

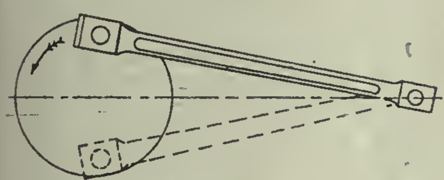

FIG. 7—CONNECTING ROD FOR STEAM ENGINE.

metal involved and the strength of that metal. As in Fig. 4, if one of the bars will resist a load of say 20,000 lbs. per square inch, two of the bars or any multiple of the unit area will resist just that many times 20,000 lbs. In the case at hand it happens that the area of section of the bars is 1 square inch, and no matter if the stress is tension, compression or shear, the two would resist 40,000 lbs., whether separate bars or joined in one of the same area.

In building construction we find parts in compression that do not come within the simple rule just stated. These are long members such as columns and supports which, because of their length have a tendency to bend in the middle under a load and have to be specially designed with this in view. They are covered by a more complicated formula.

Shear is a stress that takes its name from common household shears. The cutting of sheet metals and the numerous press punch operations are machine shop processes in which materials are so stressed on such work, the object is to sever the metal (not to have it strong enough to resist) and the mathematical side appears when it is desired to know how much resistance the part will offer to cutting and how powerful a machine will be required for the work; here again the area of the cut surface multiplied by the strength of the material gives the total resistance offered.

The commonest applications of machine parts under shear that are supposed to be amply safe against cutting off are found in forked joints such as at P in Fig. 1. Here if the pin were too light the eye end of the rod would cut it off at each side and the rod and weight would fall—the pin would be cut into three pieces, each of which would be left in the original hole. Pin connected bridges and the multitude of linkages found in machine construction all fall in this class. The arms A and C in Fig. 1 are connected to the shaft by taper pins; these pins resist a shearing stress, and if too small for the load they will cut off, the result as shown in the section at Fig. 8.

Table of Breaking Strengths

In construction and design it is customary to assume that the materials used have a certain strength per unit of area. The values given in Table II are fair average values, but different grades will show a wide variation each way from these averages. To the beginner this variation puts him all at sea and he thinks tables are worse than useless—the facts however are that steel (for instance) used for structural shapes is of such composition and manufacture that its strength does not vary more than one or two per cent from a known value, the same is true of steel used for shafting and for piano wire, and so on throughout a score of well-defined grades covering all the common uses. Engineers' handbooks gives these values in detail. In designing, steel of a certain strength is specified and the calculations for parts and sizes are made accordingly, then when the work gets to the shop the proper steel is selected, or if not in stock it is ordered from the mills to be of that strength.

The values in Table II are the "ultimate" or breaking strength of the materials. Naturally no one would want to load a piece to the breaking point, but this is the common way of stating the relative strengths and forms a more satisfactory basis for calculations than to try to table different materials under different kinds of forces with the safe loads they should bear. Common sense tells us to make a part safely strong, i.e., not to stress the part to its ultimate strength. In engineering we say the part is given "a factor of safety." Thus, if the load on a beam is going to be 2,400 lbs. and the beam is made heavy enough to hold 9,600 lbs (at which load it would be stressed to the point of failure) then we say the factor of safety is 4.

Safety Factors

The half inch rods in Fig. 2 serve as an illustration of the factor of safety. One of them holds five weights of equal size and the other one weight. Now the rod at the right does not break under its load but it is nearer breaking than the rod at the left because five times the weight puts five times the stress upon it and that stress is five times as near the ultimate strength of the steel: Assuming that ten of the weights would break the rod, then the right hand rod has a factor of safety of $10 \div 5 = 2$ and the left hand rod has a factor of safety of 10. A part that has a factor of safety as low as 2 is not considered safe for any purpose, and though there are millions of minor pieces so made, good design and safety coupled with a reasonable life of wearing surfaces demand a factor as high as 4 in all cases and often one much greater than that.

Table III gives factors of safety for a number of common uses. It will be noticed that where there is a steady load considered the factor is much lower than when the load is applied suddenly. Thus a part, as for instance a floor beam, is able to withstand a weight that is carefully placed and left there far better than the same weight if it is dumped off a truck on to the floor. A load suddenly applied puts twice the stress on any member that the same load would if existing merely as a weight. Stresses that alternate in direction need a larger factor of safety than when acting in one direction only; the connecting rod of Fig. 7 is a good example of a part so stressed and the pieces of wire that we see so often broken by bending back and forth in the hands is another. The designer sometimes chooses his own factor of safety arbitrarily, but it is better to use those given in Table III, which represent first-class practice. Every case may be resolved into one of the three classes named in the table.

Combination of Stresses

It has been stated that the stresses encountered in beams bending are but a combination of tension and compression; it should also be stated that the simple rules for these kinds of loading do not apply in the case of beams because un-

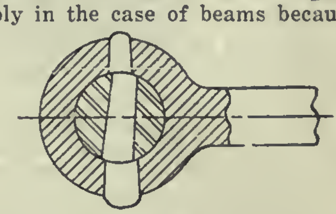

FIG. 8.

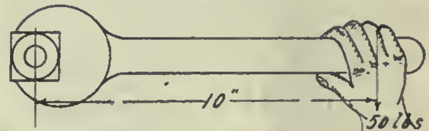

FIG. 9—ILLUSTRATION OF CANTILEVER LOADING.

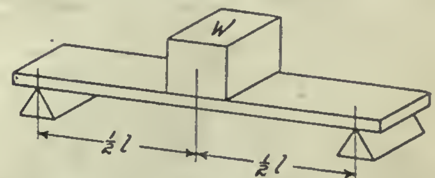

FIG. 10—BEAM WITH SIMPLEST LOADING.

der bending stresses certain parts of the beam offer greater resistance than others. The punch frame is an example of this.

The punch frame comes under the head of beams, even though it bears no resemblance to that term as used in carpentry. Any part under a bending stress is called a beam. The wrench in Fig. 9 is a cantilever beam, so is the nose of a lathe spindle, the bed of a lathe is a beam resisting the weight of parts and the pressure of the cut, a shaft is a beam supported at the hangers and loaded by pulleys and belt pulls. The plank shown in Fig. 10 represents one of the

The resisting value of each square is the product of its area by the square of the distance to its centre which gives for each square in A a value of ½ x ½ x 1 = ¼ and a total value for the entire section of 12 x ¼ = 3. The value of B is made up of the sum of the products similarly obtained — 4 x ½ x ½ x 1 (as

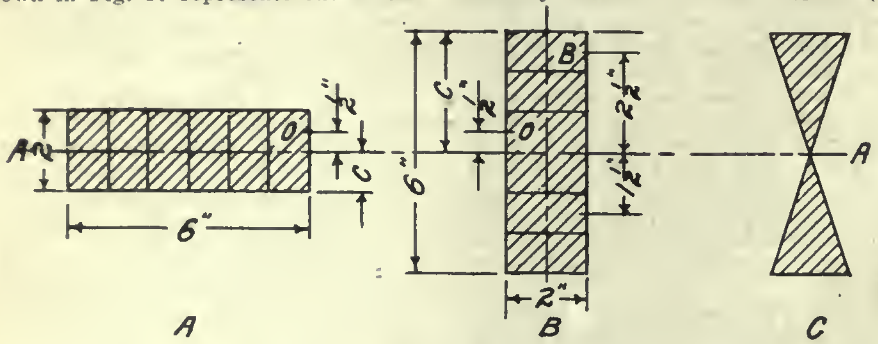

FIG. 11.

simplest beams typically loaded and supported; the length of this beam is the distance between the ridges of the triangular supports and the load W is placed midway of the supports.

Relative Strength of Beams

To show the method of determining the relative strength of beams and of the same beam in different positions, the three figures of Fig. 11 have been drawn. A and B are two views of the same 2 x 6 beam laid flat and on edge. The center line A, A, passes through the center of each; in beam calculations this line is called the "neutral axis"—the neutral axis passes through the center of gravity of any figure, which is also the horizontal center line of a symmetrical figure. There is a vertical as well as a horizontal neutral axis for every cross section but the usual method of calculating is to consider the beam laid so the working neutral axis is horizontal.

The "neutral plane" is the imaginary surface that would be formed if the neutral axis were continued throughout the entire length of the beam. The dash line in Fig. 5 indicate the position of the neutral plane as viewed from the side—it will be noted that the line is in the center of the beam both at A and B—it is the plane where the fibres are neither stretched nor compressed. An important fact in connection with the neutral plane is that none of the fibres of the material lying exactly on the plane have any value in resisting stresses, while those farthest from it have the greatest resisting value.

Turning again to Fig. 11, A and B, it will be seen that the sections have been divided into squares 1 inch on a side, a way that is made more accurate by decreasing the size of the squares. The area of the squares and the distance from the neutral axis to the center of each square are the factors in the calculation. In this example the area of all the squares is 1 sq. in.; at A, the distance of all the squares from the neutral axis is ½ in., while at B there are three distances and only four of the squares are ½ in. from the neutral axis.

before) plus 4 x 1½ x 1½ x 1 plus 4 x 2½ x 2½ x 1 = 35.

The sum of these products—3 in one case and 35 in the other—is called the "moment of inertia," a value of the highest importance in beam calculations (the words moment and inertia as here used have no connection with other meanings and applications). Another value frequently used is obtained by dividing the moment of inertia by the distance from the neutral axis to the extreme fibre of the section (as the distance C in Fig. 11). The result is called the "section modulus." The section modulus of A then would be 3 ÷ 1 = 3 and the section

FIG. 12—ANVIL AND MEANS FOR SUPPORTING.

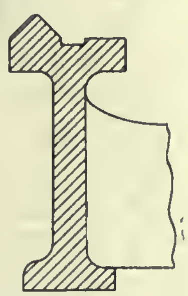

FIG. 13—SECTION THROUGH LATHE BED.

modulus of B would be 35 ÷ 3 = 11 2-3. The section modulus is often called the "resisting inches" and is a value more readily comprehended by referring to Fig. 11, C; C has much less area than B, but if each of the squares in B had an equal resisting value and that value was like the value of the extreme fibres in B, a beam of the size of C would be as strong as the beam B which is twice as heavy. The section modulus as shown at C is a graphic representation of the actual load-resisting value of every particle of material in the beam B—the fibers on the center line have no strength at all but as we move away their strength increases as rapidly as the increase of size of the triangles in C whose apexes are on the center line.

As shown in the preceding paragraph the section modulus of the beam on its side is 3 and of the same beam on edge is 11 2-3; this is the actual ratio of their strengths. If we could obtain the section modulus directly we would not need the moment of inertia, in fact the latter is chiefly useful as a means to an end. In using formulas for calculating the strength of beams we always find either the moment of inertia or the section modulus and we use the values for these according to the size and shape of the particular beam. Instead of having to divide each section into minute squares and obtain the moment of inertia in this way, there have been worked out brief formulas for all structural shapes and regular cross sections, and it is then only necessary to substitute actual sizes to get the resistance of the beam. In most engineering works the moment of inertia is represented by I, the distance from the neutral axis to the extreme fibers by c, and the section modulus by $\frac{I}{c}$—which fraction shows the division we have just been discussing.

Distribution of Metal

The applications of the proper distribution of material in beams are almost too numerous to select from. Fig. 13 is a partial section through a lathe bed showing one of the I-shaped sides which has a deep web and flanges at the extremes of the web—a shape that gives a high value to the section modulus with a comparatively light weight. The familiar U clamp used for fastening work on planers and drills and boring machines is a lowly example of a piece where we should stand the beam on edge to get greater stiffness, something the blacksmith should do when forging these necessaries.

Another instance, but one that is not rectangular, is shown in Fig. 14. It was desired to convert a solid spindle of a lathe into a hollow one but it was feared that cutting away the metal would weaken the spindle too much. The size of the spindle at the front bearing was 2 ins., at the rear bearing 1¼ ins., and a ⅞ in. hole was wanted. Substituting these values in the formulas for solid and for hollow rounds, the section modulus for the front bearing is found to be .785 and .756 respectively, showing the remarkable fact that the spindle is weakened but 3 per cent. by drilling the hole

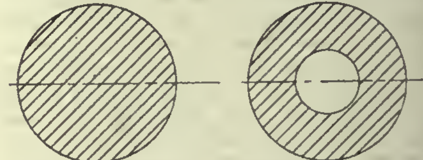

FIG. 14—SOLID AND HOLLOW ROUND SHAFTS.

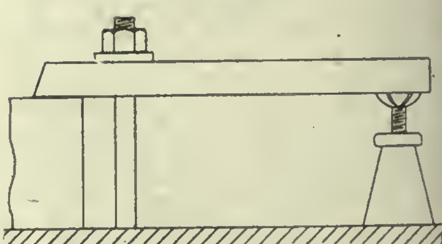

FIG. 15.

through. At the rear bearing the results are .122 and .076, which is a loss of strength of 37 per cent.; a greater proportionate loss because the diameter of the outside is nearer that of the hole but a loss that did not affect the strength of the spindle seriously because of the nature of the work and the distance of the rear end from the point of application of the load.

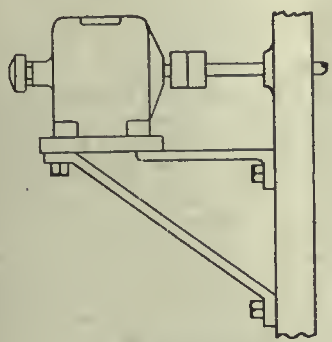

FIG. 16—MOTOR BRACKET

The example just cited is a typical one for tubular or box construction—the farther away from the center that the metal can be placed the stronger will the member be; also the metal at the exact center has no resisting value and very little within quite a distance of the center. There is a popular fallacy connected with tubing, however, that will bear correcting at this time. A tube is not stronger than a solid piece of the same outside shape and the same weight.

The matter of stiffness must also be considered in connection with beams. While a beam might be strong enough to carry all the load that ever will be put upon it and have a good margin of safety, it still might spring or vibrate so much as to give altogether unsatisfactory results. A good example of this is shown in Fig. 12 where an anvil is located on a floor that would be considered substantially constructed but which would vibrate too much for the blacksmithing to be done. The shop floor is located but a few feet above the ground and the natural footing therefore was to run a post down to a masonry foundation, the post bein gan example of a part in compression, subject to a steady load (the anvil, block and flooring) and to shocks from the hammering.

Stiffness, the proportioning of beams, the effects of loads differently placed—all these follow in easy succession when the elements become firmly placed in the mind. And the work is not hard to understand. Interesting examples are all about in shop work, factory construction, repairs and design—such as indicated by Fig. 16 where it was required to apply a motor weighing 900 lbs. to a special machine; it had to be located as shown and the designing of suitable brackets and frame was given to one of the shop men who had been "studying nights." The arrangement proved quite successful and earned complimentary remarks for the designer from engineers who later viewed the work. This is but an instance of the opportunities ever present for an application of Strength of Materials.

TEXTILE BELTINGS

By Mark Meredith

One of the effects of this, as of previous wars, has been to send up the price of leather. Prices, as a matter of fact, were advancing before the war, but they are now about 33½ per cent. above the normal. This has led to a big increase in the cost of all mill supplies derived from leather, and has also caused manufacturers and other users of power to prosecute inquiries as to the relative efficiency of other means of power transmission. Thus the various forms of textile beltings on the market have been given a unique opportunity of proving their efficiency and economy. No transmission can be termed cheap, no matter how low the initial cost, if it involves loss of power. Efficiency is the first requisite of any product that has to compete with the older style of power transmission by means of leather. As a matter of fact, textile belting has been in practical use for about half a century, and during that time has given abundant proof of its durability and efficiency.

The best types of textile belting on the market are made either of hair or balata. Hair belting, which is 50 per cent. cheaper than leather is simply a solid woven fabric made up in different thicknesses and composed of certain grades of hair and woolen yarns combined with cotton. Balata belting is about 25 per cent. cheaper than leather. It is made from very strong cotton cloth known as "duck," which is saturated with a soluation of balata, folded to the required width and ply under heat, and then stretched on powerful straining heads, where it is allowed to cool and set dead under tension. This prevents shrinkage, and except within the narrowest limits, any possibility of stretch afterwards. Balta, it may be explained, is a milky latex obtained in the same manner as rubber, by tapping. It is, indeed allied to both rubber and gutta-percha, but has certain properties peculiar to itself. It is waterproof, but has only enough elasticity to prevent brittleness. Sheet balata, which obtains the highest price, is obtained from the Guineas, and block balata from Venezuela. The hair belting is a very efficient form of transmission. One of its virtues is that it is not susceptable to atmospheric conditions as other forms, whilst its adaptability makes it particularly suitable for outdoor work. In textile factories it has long been used with success for mule down drives, top-straps and for ringspinning frames, but its grip has been found too positive for loom straps, which are required to slip off the fast pulley quickly when the loom stops. The condition of the loom, however, is exceptional, and what is a virtue for leather in the case of the loom would prove a serious loss of power in cases where regular driving is essential. Balata belting in consequence of its method of construction possesses a very good driving face. It is possible to add to the number of plies and thus increase the thickness so as to transmit the highest loads. In that, too, it has an advantage over leather. Moreover, it can be made to any length, of an even strength throughout, and it is therefore largely used where it is necessary to reverse the drive, or where guide pulleys are employ-d. The best practice is to use thin belts as there is less danger of rupture between the plies in bending round the pulleys. A thin belt clings to the pulley much better than a thick one. Balata belting is especially suitable for pulp and paper mills, engineering shops, and places where heavy continuous driving is necessary.

Future of Textile Belting

The prospects for making of textile beltings are exceedingly bright, seeing that the German and Austrian supplies are cut off by the war. The competition of German manufacturers was exceptionally keen, as they were content to work on the narrowest margins, while the usual German methods were employed on allowing consigned goods an exceptionally extended credit. This enabled them in markets such as Italy, Spain, and other continental countries practically to oust English manufacture in the ordinary qualities of belting. Not only is textile belting used to a greater extent for power transmission, but its serviceability for conveying loads from point to point is being proved in an increasing number of ways. In the large stores it is now the universal practice to send goods to be packed and afterwards to their delivery stations along conveyor belts. They are, however, put to much severer tests in quarries and collieries, and to-day textile beltings are being regularly employed for conveying coal, coke, limestone, cement, granite, quartz, chalk clay, sand, and many other materials. This is an age of enquiry, and the up-to-date head of a factory or workshop carefully figures out the cost of his coal bill in comparision with the steam power generated in the engine-room. Let him also look into the methods of transmitting that power, to see if some of the leakage that takes place cannot be lessened by up-to-date driving.

It has been shown by experiment that the sulphur contained in coal in the form of pyrites is not the chief source of spontaneous combustion, as was formerly supposed, but the oxidation of the sulphur in the coal may assist in breaking up the lumps of coal, and thus may increase the amount of fine coal which is particularly liable to rapid oxidation. Even this opinion is not unanimously endorced. In spite of experimental data showing that sulphur is not the determining element in spontaneous combustion, the opinion is widespread that, if possible, it is well for storage purposes to choose a coal with a low sulphur content.

How Hun Plotters Worked in U.S. Before the War

Did Everything Possible to Prevent the Export of Munitions to Allies—How the Whole Thing Has Been Exposed by the U.S. Authorities Who Investigated the Whole Performance

By EARL E. SPERRY and WILLIS WEST for U. S. Committee on Public Information.

ONE chief purpose of the German and Austrian ambassadors was to prevent the export from the United States of military supplies. Since Germany's shipping had been driven from the seas early in the war her overwhelming superiority in accumulated munitions and in power to manufacture was certain to be lost as the passing months brought to the Entente states an increasing volume of American products.

To strike at the very source of these supplies, the American factory, was obviously an effective means to prevent their export, and in a letter to Baron Burian, Foreign Minister of Austria-Hungary, Ambassador Dumba writes concerning this design:

> Besides, a private German employment office has been established which provides employment for persons who have voluntarily given up their places, and it is already working well. We shall also join in and the widest support is assured us.

This German employment bureau had a central office in New York City, Chicago and Cincinnati. It was established early in August, 1915, by the attaches and responsible agents of the German and Austrian embassies. Liebau, its manager, said that "among those who were active in opening this bureau were Professor Kuhnemann, exchange professor at Harvard University, Professor Munsterberg . . . and the German Club of New York City."

Its revenues consisted in part of gifts from private sources. These were solicited, among others, by Dr. Karl O. Bertling, who was provided with the following letter:

> Imperial German Embassy,
> Washington, Nov. 4, 1916.
>
> I hereby permit myself to recommend to you most warmly Dr. Karl O. Bertling, Direktor of the Amerika-Institute in Berlin. Dr. Bertling will take the liberty to lay before you some matters pertaining to the activity of the Central Bureau for German and Austro-Hungarian workmen. This work as well as the collection of funds for its further extension are worthy of all sympathy.
>
> Dr. Bertling is authorized to receive contributions in any amount. Checks are to be made payable to Hans Liebau, Treasurer.
>
> Yours with apecial respect,
> (Signed) J. von Bernstorff.

When gifts began to lessen in amount the two governments concerned had to contribute more liberally to the support of the bureau, and the arrangement made is thus described by Mr. R. H. Otto, former German consul at Kingston, Jamaica:

> I wrote to the German Embassy covering the whole matter and suggesting that the German Government subsidize the Bureau by a regular contribution of funds. I heard nothing of it for months, but one day received a telephone message from Dr. Heinrich F. Albert to see him at his office, 45 Broadway. When I arrived there, he told me the German Embassy had authorized him to supply our Bureau with funds up to $2,000 per month. He then gave me $2,000 in greenbacks, mostly in $100 bills. . . . . Whenever I learned from Mr. Liebau that money was needed for the Bureau, I gave Dr. Albert 24 hours' notice and went and got the money from him. . . . . In all, I must have turned over to Liebau between $24,000 and $30,000.

The pretended purpose of the bureau was to provide employment for German and Austrian subjects who had voluntarily left positions in factories supplying the allies.

Its real purpose is disclosed in the following letter from Liebau to a German employed in such a factory:

> Mr. ——— Sept. 24, 1915.
> Brooklyn.
>
> As we have heard that you are employed in one of the many factories which deliver war material to the enemies of Germany, we wish to call your attention to the fact that according to the notice published in many newspapers, under Section 89 of the German Criminal Code, you are guilty of treason if you are a German subject.

That coercion and intimidation were regularly used by the bureau to drive employees from munition factories has been proved by an examination of over 5,000 letters and other papers in its files. The Austrian government reinforced these efforts by circulating in this country, through the foreign language press, a proclamation which threatened with a penalty of ten to twenty years' imprisonment all subjects who after working in such plants returned to their native land. Captain von Papen also sent out a circular letter of similar import.

Success rewarded these energetic efforts to harass American manufacturers. Liebau's monthly report, made to the German Embassy for February, 1916, contains the following statements:

> Since the Bureau began its work in August, 1915, through February, 1916, 2,828 Germans and 1,638 subjects of the Austro-Hungarian monarchy have been provided for. The total number of applicants is now 8,000. Of these 60 per cent. came from factories producing munition and war material, and 40 per cent. would have been employed in such plants if the agency had not provided for them. . . .
>
> Engineers and persons in the better class of positions. . . . were persuaded by the propaganda of the Bureau to leave war material factories. . .
>
> The commercial employment bureaus of the country have no supply of unemployed technicians. . . . Many disturbances and suspensions which war material factories have had to suffer, and which it was not always possible to remove quickly, but which on the contrary often lead to long strikes, may be attributed to the energetic propaganda of the employment bureau.

Causing Strikes

The strike was a weapon which both the German and Austrian ambassadors intended to use with destructive effect on American industry. Ambassador Dumba, in a letter to his Foreign Office, thus expressed their fundamental purpose:

> It is my impression that we can disorganize and hold up for months, if not entirely prevent, the manufacture of munitions in Bethlehem and the Middle West, which in the opinion of the German Military Attache, is of importance and amply outweighs the comparatively small expenditure of money involved. . .

The most comprehensive and successful effort to provoke strikes was made by Labor's National Peace Council, an organization financed by Franz von Rintelen, who came to the United States early in April, 1915.

The alleged purpose of the council was to express the pacific sentiments of the workers and to prevent the United States from entering the war. At its first meeting, on June 22, 1915, it adopted among others the following resolution:

> Resolved, By the representatives of labor in Peace Congress assembled in the City of Washington, that an organization be and is hereby established, to be known as Labor's National Peace Council, having for its purpose the establishment and maintenance of peace universal by all honorable means. . . .

The president of the council, Congressman Frank Buchanan, wrote to President Wilson the next day, stating that a committee of the council desired an interview in order to acquaint him with the resolutions adopted. The President's secretary replied that, owing to business of urgent importance it had been impossible for President Wilson, during a brief stay in Washington, to see the committee. Buchanan then wrote the following letter, designed to express the pretended spirit and purposes of the council:

> Labor's National Peace Council,
> Chicago, Ill., July 28, 1915.
>
> Hon. J. P. Tumulty,
> The White House,
> Washington, D.C.
>
> My Dear Mr. Tumulty:—
>
> (Opening paragraph acknowledges letter).
>
> Your intimation that the President's time was so fully taken up with matters of pressing importance, that he could not grant an audience to the representatives of Labor, that has made the United States of America the proud nation that it is, in order to permit them in person to demonstrate that the subsidized press, representing organized dollars in America, which is seeking to serve as the volunteer adviser of the President, was misrepresenting Labor's attitude in the present crisis, is tantamount to a declaration that the President is more concerned about the desires of Big Business than he is to discover the heartfelt sentiment of the common people.
>
> As is well known, I, by the vote of the people, was taken from the ranks of America's toilers to serve them in the Hall

of Congress and as their representative to voice their opinion on national questions. As a Trades Unionist I found that the first lesson taught by Organized Labor was to implant in the heart and minds of its members "The Ethics of Humanity and the Sacredness of Human Life."

I thank you, Mr. Tumulty, for your candor. My duty to those I serve leaves me no alternative but to say that so long as they, the people whom I serve, continue to be united in their belief that progress and prosperity is dependent upon religious observance of the scriptural admonition, "and they shall beat their swords into ploughshares, and their spears into prunings hooks; nation shall not lift up sword against nation, neither shall they learn war any more;" just so long shall I continue to rap at the door of the President's private chambers to secure admittance for a delegation of workers "Who Not Only Desire Peace at Home But Peace Abroad as Well."

Awaiting your reply, I have the honor to be,

Very truly yours,

Frank Buchanan.

The pretended purposes of Labor's National Peace Council as stated by Congressman Buchanan were in striking contrast to its real purposes as stated to the jury by several witnesses. Among these was Ernest Bohm, its treasurer and a labor leader, who testified that he was asked by Henry Martin, one of the Council's organizers to assist in provoking strikes in munition factories, and if successful he was to receive $5,000 to $10,000. Labor agitators were hired who visited the munition centers in the eastern part of the United States and caused strikes in several cities, including Schenectady, N.Y., Ilion, N.Y., and Bridgeport, Conn.

The following telegram is a typical report from one of these men to his employer.

July 28, 1915.

H. B. Martin,
Hotel Sherman,
City Hall Square,
Chicago, Illinois.

Organizers from States where war munitions are manufactured were in session in Bridgeport last night. Talked with them. Strikes liable to occur. Reports show that workers are ready to enforce demands. Fresh trouble for makers of general war supplies will break out all over the country.

William Delehanty.

Strikes in other industries, also by railway employees and by marine engineers and firemen, were planned by the leaders of the council.

A serious attempt was made to paralyze America's foreign commerce by a strike of stevedores. One of Rintelen's men had an interview with the president of the International Longshoremen's Union, and other officials were approached. Rintelen agreed to pay the strikers ten dollars a week while idle, and asserted that he could command the $1,035,000 necessary for this purpose. He spent $10,000 on this project, but the strike did not occur.

Along with Lamar, Buchanan, ex-Congressman Fowler, Martin, Monett, and two others, all of whom had assisted in the work of the Council, Rintelen was indicted by the Grand Jury on December 28, 1915, for "conspiracy to restrain the manufacture, transportation, and export of munitions of war." Among the means employed to accomplish these purposes the indictment specifies the instigation of strikes by solicitation, by the dissemination of letters, circulars and newspaper articles, by bribery, and by the distribution of money to labor leaders. Rintelen, Lamar, and Martin were found guilty, and on May 21, 1917, were each sentenced to one year's imprisonment. The indictment against Monett was dismissed and the jury disagreed as to the others.

The amount of money which Rintelen had at his disposal was stated by George Plochman, treasurer of the Transatlantic Trust Co., where Rintelen kept his accounts, to be $508,000, which was transmitted from Germany through the Hamburg-American Line.

A photographic copy of Rintelen's accounts with the Transatlantic Trust Company shows that while Labor's National Peace Council was being organized and operated, he paid out the following sums of $1,000 or over:

April 10 (1915)	$1,000
" 12	1,000
" 13	3,500
" 17	1,000
" 22	2,100
" 28	12,500
May 3	3,500
" 5	2,000
" 11	15,000
" 13	2,000
" 20	1,000
June 4	70,000
July 14	2,500
" 16	10,600
" 20	25,000
" 23	1,000
" 27	20,000
" 31	25,000
Aug. 2	25,000

Under the name E. V. Gibbons & Co. he also paid out the following amounts:

April 22	$3,000
" 26	6,000
" 28	2,500
" 30	2,500
May 17	2,500
" 18	18,000
" 20	4,400
" 25	1,500
" 29	1,300
June 1	30,000
" 7	1,500
" 12	20,000
" 18	25,900
" 24	26,500
" 30	5,500
July 2	2,600
" 8	1,500
" 10	3,000
" 13	7,600

The total of his known expenditures was $468,000, and in return he received almost nothing except an occasional newspaper article attacking President Wilson. Nearly all the strikes which his hired men pretended they had started and for which they received thousands of dollars had quite other causes. Rintelen was shamelessly duped and swindled by his supposed tools.

Pressure on Congress

The hand of the German government was extended to America to influence members of Congress through German-American voters and their sympathizers. The German-American National Alliance had long endeavored to weld persons of German descent in the United States into a compact body, to be used, when desirable in the interests of Germany. After the war began in July, 1914, prominent German-Americans organized and supported other societies which aimed to persuade or intimidate members of Congress into adopting pro-German poilcies.

One of these organizations was the American Embargo Conference, established to prevent the export of munitions. That it was recognized as a valuable tool of the German government and probably received money from Berlin is shown by the following telegram (September 15, 1916) from Count Bernstorff to the German Foreign Office:

The Embargo Conference in regard to whose earlier fruitful co-operation Dr. Hale can give information is just about to enter a vigorous campaign to secure a majority in both houses of Congress favorable to Germany and request further support. There is no possibility of our being compromised. Request telegraphic reply.

The Embargo Conference distributed to voters over 5,000,000 telegrams demanding an embargo on munitions, and at a fixed date 250,000 of these identical messages poured into Washington. The conference paid to the telegraph companies in Chicago alone the sum of $20,000. It also distributed pamphlets and circular letters demanding an embargo and denouncing American makers of munitions.

Although the officers of the conference asserted that it was supported by small popular subscriptions, its cash book shows that the $57,000 received from July, 1915, to June, 1916, consisted of sums varying from $400 to $1,000, and given, as a rule by prominent German-Americans of New York, Chicago, Cincinnati, and Detroit. One gift of $5,000 came from an international banking firm in New York City.

The embargo conference apparently served the German government well, for Count von Bernstorff, in the following telegram to Berlin, requests $50,000 to be spent either on this or a similar organization aiming to force pro-German policies on Congress:

I request authority to pay out up to $50,000 (fifty thousand dollars) in order, as on former occasions, to influence Congress through the organization you know of, which can perhaps prevent war.

I am beginning in the meantime to act accordingly.

In the above circumstances a public official German declaration in favor of Ireland is highly desirable, in order to gain the support of the Irish influence here.

The actual bribery of Congressmen apparently was intended by Franz von Rintelen. According to Meloy, he supplied Lamar with money to be used in procuring the passage of resolutions by Congress which should embarrass the government in the conduct of its relations with Germany. Both Congressmen Buchanan and ex-Congressman Fowler received money for their assistance in attempting to bribe Congress. That such was Rintelen's intention was also stated explicitly by George Plochman, treasurer of the Transatlantic Trust Company where Rintelen kept his accounts.

Causing War With Mexico

Rintelen also tried to prevent the export of munitions by causing war between the United States and Mexico. During his trial at New York City (May, 1917), one of the witnesses, an advertising man with whom Rintelen advised concerning his pacifist propaganda, testified that Rintelen said:

That he came to the United States in order to embroil it with Mexico and Japan if necessary; that he was doing all he could and was going to do all he could to embroil this country with Mexico; that he believed that if the United States had a war with Mexico it would stop the shipment of ammunition to Europe; that he believed it would be only a matter of time until we were involved with Japan.

Rintelen also said that General Huerta was going to return to Mexico and start a revolution there which would cause the United States to intervene and so make it impossible to ship munitions to Europe. Intervention, he said, was one of his trump cards.

Within Mexico itself other German agents have been conducting for many months a powerful anti-American propaganda. Their aims are to destroy American prestige by teaching that the United States is impotent, unable even to prepare for war, and that Japan is its enemy; also to create implacable hostility to the United States by asserting that it aims to control or conquer Mexico.

The culmination of Germany's attempt to provoke war between the United States and Mexico is the following telegram sent by the German Foreign Office to Count von Bernstorff for transmission to the German Ambassador in Mexico, Heinrich von Eckhardt:

Berlin, January 19, 1917.

On the first of February we intend to begin submarine warfare unrestricted. In spite of this, it is our intention to endeavor to keep neutral the United States of America. If this attempt is not successful, we propose an alliance on the following basis with Mexico: That we shall make war together and together make peace. We shall give general financial support, and it is understood that Mexico is to reconquer the lost territory in New Mexico, Texas, and Arizona. The details are left to you for settlement. You are instructed to inform the President of Mexico of the above in the greatest confidence as soon as it is certain that there will be an outbreak of war with the United States, and suggest that the President of Mexico, on his own initiative, should communicate with Japan suggesting adherence at once to this plan; at the same time, offer to mediate between Germany and Japan.

Please call to the attention of the President of Mexico that the employment of ruthless submarine warfare now promises to compel England to make peace in a few months.

ZIMMERMANN.

Destruction of Ships and Their Cargoes

If strikes should fail to close American munition plants, if money were lacking to buy up all their products, and if the government refused an embargo, Germany's agents had yet another resource —to destroy war materials and other supplies for the Entente States while in course of shipment by sea. One project of this kind was carried out under the direction of Captain von Papen and Wolf von Igel. It consisted in placing in the holds of steamers incendiary bombs which, at a fixed time, would explode and ignite the surrounding cargo. The bomb shells were manufactured from designs by Dr. Walter T. Scheele, a German chemist of Hoboken, on the Friedrich der Grosse of the North German Lloyd line, and were then taken to Dr. Scheele's laboratory and filled with combustibles.

When the conspirators were tried, one of the witnesses called was a detective who belonged to the New York bomb squad and had worked on the case. Under the pretense that he was a German secret service man employed by Wolf von Igel, he had succeeded in making an appointment with Captain von Kleist, superintendent of Scheele's factory, and thus recounted the conversation with him:

We sat down and we spoke for about three hours. . . . I asked him the different things that he did, and said if he wanted an interview with Mr. von Igel, my boss, he would have to tell everything. So he told me that von Papen gave Dr. Scheele, the partner of von Kleist in this factory, a cheque for $10,000 to start this bomb factory. . . . He told me that he, Mr. von Kleist, and Dr. Scheele and a man by the name of Becker on the "Friedrich der Grosse," were making the bombs, and that Captain Wolpert, Captain Bode, and Captain Steinberg, had charge of putting these bombs on the ships; they put these bombs in cases and shipped them as merchandise on these steamers, and they would go away on the trip and the bombs would go off after the ship was out four or five days, causing a fire and causing the cargo to go up in flames. . . . He also told me that they have made quite a number of these bombs; that thirty of them were given to a party by the name of O'Leary, and that he took them down to New Orleans where he had charge of putting them on ships down there, this fellow O'Leary.

Between 300 and 400 bombs were manufactured, and fires were started by them on thirty-three ships sailing from New York alone.

Four of the bombs were found at Marseilles on a vessel which sailed from Brooklyn in May, 1915. The evidence collected in the case led to the indictment of the following men for feloniously transporting on the steamship Kirk Oswald a bomb or bombs filled with chemicals designed to cause incendiary fires: Rintelen, Wolpert, Bode, Schmidt, Becker, Garbade, Praedel, Paradies, von Kleist, Schimmel, Scheele, Steinberg, and others. The last three named fled from justice, Scheele being supplied with $1,000 for that purpose by Wolf von Igel. He eluded the Federal authorities until April, 1918, when he was found hiding in Cuba under the protection of German secret service agents. All the others except Schmidt were found guilty and sentenced, on February 5, 1918, to imprisonment for eighteen months and payment of a fine of $2,000 each. It was proved during the trial that Rintelen had hired Schimmel, a German lawyer, to see that bombs were placed on ships.

Schmidt, von Kleist, Becker, Garbade, Praedel and Paradies had already been tried for conspiracy to make bombs for concealment on ocean-going vessels with the purpose of setting the same on fire. All were found guilty, and on April 6, 1917, von Kleist and Schmidt were sentenced to two years' imprisonment and a fine of $5,000 each; the others to six months' imprisonment and a fine of $500 each. Wolpert and Bode, also indicted, obtained the privilege of a separate trial, which has not yet been held.

Robert Fay, a former officer in the German army, who came to the United States in April, 1915, endeavored to prevent the traffic in munitions by sinking the laden ships at sea. In recounting the circumstances of his arrival here to the chief of the United States Secret Service, Fay said:

. . . I had in the neighborhood $4,000. . . . This money came from a man who sent me over . . . (named) Jonnersen. The understanding was that it might be worth while to stop the shipment of artillery munitions from this country. . . I imagined Jonnersen to be in the (German) Secret Service.

After stating that he saw von Papen and Boy-Ed and that neither would have anything to do with him, apparently because suspicious of his identity, Fay continued:

I did not want to return (to Germany) without having carried out my intention, that it, the destruction of ships carrying munitions. I proceeded with my experiments and tried to get hold of as much explosive matter as in any way possible. . . .

Fay and two confederates were arrested in a lonely spot near Grantwood, New Jersey, while testing an explosive. During his examination at police headquarters in Weehawken immediately after the arrest he was questioned as follows:

Q—That large machine you have down stairs, what is that? A—That is a patent of mine. It is a new way of getting a time fuse. . . .

Q—Did you know where Scholz (Fay's brother-in-law) had this machine made? A—In different machine shops. . . .

Q—What material is it you wanted (from Daeche, an accomplice)? A—Trinitate of toluol (T. N. T.). . . .

Q—How much did the machinery cost? A—Roughly speaking, $150 or $200. . . .

Q—What would be the cost of making one and filling it with explosive? A—About $250 each. . . . If they had given me money enough I should simply have been able to block the shipping entirely.

Q—Do you mean you could have destroyed every ship that left the harbor by means of those bombs? A—I would have been able to stop so many that the authorities would not have dared (to send out any ships).

It was proved during Fay's trial that his bomb was a practical device and that its 40 pounds of explosive would sink any ship to which its was attached.

Fay and his accomplices, Scholz and Daeche, were convicted of conspiracy to attach explosive bombs to the rudders of vessels, with the intention of wrecking the same when at sea, and were sentenced on May 9, 1916, to terms of eight, four, and two years respectively in the Federal penitentiary at Atlanta. Dr. Herbert Kienzle and Max Breitung, who assisted Fay in procuring explosives, were indicted on the same charge, but have not been tried. Both are interned.

Another plan for disabling ships was suggested by a man who remained for some time unknown. He called one day at the German Military Information Bureau, maintained at 60 Wall Street by Captain von Papen, of the German Embassy, and there gave the following outline of his plan:

I intend to cause serious damage to vessels of the Allies leaving ports of the United States by placing bombs, which I am making myself, on board. These bombs resemble ordinary lumps of coal and I am planning to have them concealed in the coal to be laden on steamers of the Allies. I have already discussed this plan with . . . . at . . . . and he thinks favorably of my idea. I have been engaged on similar work in . . . after the outbreak of the war, together with Mr. von . . . .

The German secret service report from which the above exerpt is taken states that the maker of the bomb was paid by check No. 146 for $150 drawn on the Riggs National Bank of Washington. A photographic copy of this check shows that it was payable to Paul Koenig of the Hamburg-American Line and was signed by Captain von Papen. On the counterfoil is written this memorandum, "For F. J. Busse." Busse confessed later that he had discussed with Capt. von Papen at the German Club in New York City the plan of damaging the boilers of munition ships with bombs which resembled lumps of coal.

A similar scheme was conceived by Albert Kaltschmidt of Detroit, who hoped, however, not only to disable ships but to destroy them entirely. He hired Charles Respa, Richard Hermann, and a man known as "Frenchy," for $150 each to undertake this work. Provided with an ample supply of dynamite, painted to resemble coal, they went to New York City and tried by the use of a launch to approach coal barges and place the dynamite in the fuel intended for ocean going steamers. Guards were so vigilant, however, that nothing could be accomplished.

Germany's official representatives on the Pacific coast were engaged in similar enterprises. The leader was Franz Bopp, German Consul-General at San Francisco. His chief assistants were Baron Eckhardt von Schack, the vice-consul, Lieutenant Wilhelm von Brincken of the consulate, and Charles C. Crowley, a detective employed by Bopp as secret investigator.

Lewis J. Smith, a confederate, describes a part of their operations in a statement made to Federal officials. After he had told about his first meeting with Crowley, the United States Attorney asked him the following questions:

Q—When Crowley came to your house on Sunday (May 8, 1915) what was it he wanted? A—He asked me what I was doing. I told him that I had just left the Pinole Powder Works and was not doing anything at that time. He says, "Well, would you accept a job as watchman?" I looked at him for a second and says, "Watchman, what kind of a watchman?" "Well," he says, "kind of watching what is loaded on boats and so on." . . . I said, "What kind of a job is this?" "Well," he said, "there is some powder to leave here to-day or to-morrow, and we want you to leave here and be in Seattle." So I said, "What's in this job?" and he said, "Three hundred dollars a month and all expenses." So I said to myself, "I will try this." . . . . And Crowley paid me $250.

Smith went to Tacoma, and after his return to San Francisco had several conversations with Bopp, concerning which he testified as follows:

Q—What did he (Bopp) say he wanted you to do? A—He said it would be a matter of watching and spotting and if there was anything to blow up I was to help him.

Q—Bopp said that? A—Yes. . . .

Q—Well, then, Bopp told you that he wanted you to watch and also help blow up things? A—Whatever Crowley told me.

Q—Well, he mentioned blowing up things, did he? A—Yes.

Smith thus told about the payment which he and Crowley received for their services:

Q—How were you paid? A—Mr. Bopp paid.

Q—In currency? A—Yes; . . . and Crowley gave a receipt.

Q—Did you give a receipt? A—Yes.

Q—And was your receipt to Bopp? A—Yes.

Johannes H. van Koolbergen, born in Holland and naturalized in Canada, made a statement before British officials at San Francisco, concerning his relations with Consul-General Bopp. After describing a pretended attempt to blow up a tunnel on the Canadian-Pacific Railroad, van Koolbergen says that he was again summoned to meet von Brincken and that the following conversation occurred:

I went to the Palace Hotel in San Francisco. Von Brincken took me to his room . . . . and explained to me how an instrument could be made for the purpose of causing an explosion at the time set, and asked me if I was capable and willing to make such an Instrument, and asked me how much I would want for it. He explained to me that a club or association of fifteen Germans who all worked as longshoremen on the docks of San Francisco would have access to outgoing boats and could place one or more of these infernal machines on board boats of German enemies. . . .

The whole had to be small enough to go into a thermos bottle. The object of it being that a man at the harbor could carry a thermos bottle with him without being suspected of having anything injurious or dangerous with him.

Van Koolbergen then describes the making of a dummy bomb and proceeds thus:

I then went to see von Brincken in his room and showed him my work and he exclaimed that it was "famos." . . . Mr. Bopp (who saw it at the consulate) said that Mr. von Brincken was very satisfied with this machine and ordered the thermos bottle put in the safe, where I saw it yesterday, August 26, 1915.

Free access to Allied ships laden with supplies for Vladivostock would be invaluable to the conspirators, and in order to obtain it, Crowley resorted to the extraordinary scheme revealed in the following letter to Madam Bakhmeteff, wife of the Russian Ambassador to the United States:

Mme. J. Bakhmeteff, Care Imperial Russian Embassy, Newport, R.I.:

Dear Madam:—By direction of the Imperial Russian Consul General of San Francisco I beg to submit the following on behalf of several fruit growers of the State of California. As it is the wish of certain growers to contribute several tons of dried fruit to the Russian Red Cross they desire to have arrangements made to facilitate the transportation of this fruit from Tacoma, Washington, to Vladivostock, and we are advised that steamships are regularly plying between Tacoma and Vladivostock upon which government supplies are shipped and we would like to have arrangements made that these fruits as they might arrive would be regularly consigned to these steamers and forwarded. It would be necessary, therefore, that an understanding be had with the agents of these steamship lines at Tacoma that immediate shipments be made via whatever steamers might be sailing.

It is the desire of the donors that there be no delay in the shipments as delays would lessen the benefits to those for whom the fruit was provided. . . .

Respectfully yours,
C. C. CROWLEY.

The statements of Smith and van Koolbergen, combined with a mass of other evidence consisting in part of letters and telegrams, caused the Grand Jury to indict Consul-General Bopp, his staff and his hired agents for conspiracy to undertake a military enterprise against Canada. Among the purposes of this enterprise specified in the indictment was the following:

To blow up and destroy with their cargoes and crews any and all vessels belonging to Great Britain, France, Japan or Russia found within the limits of Canada, which were laden with horses, munitions of war, or articles of commerce in course of transportation to the above countries. . . .

In his charge to the jury the judge who presided at the trial reviewed the testimony given by the more important witnesses, among whom was Louis J. Smith. After describing how he was taken to Lieut. von Brincken by an employee of the German Consul-General, Smith testified:

Mr. von Brincken then asked me if I would take a job of following a barge of dynamite to Seattle, and exploding it in the harbor, to prevent it going on the boat. I told him I would.

Smith met Crowley the next day and the judge thus summarized Smith's testimony concerning their conversation:

Crowley (Smith says) told him that there would be other work, and wanted to know if he would put a few bombs on some of the ships up there; that quite a bit of ammunition was going to the Allies from Tacoma, and Smith told him he would. . . . He says that von Brincken came in a few minutes, and Crowley told him that he (Smith) was willing to take the job . . . and that von Brincken wanted to know if Smith would put bombs on boats as well as on the barge, and that he told von Brincken he would.

As the first ships marked for destruction sailed from Tacoma, Smith rented a house there with half cleared land attached, in order that he might have dynamite in his possession with the intended purpose of blowing up stumps. Crowley followed him to Tacoma within a day or two, and Smith's narrative of the events there is thus given in condensed form by the judge:

When the Talthybius (a British freighter) was ready to sail Smith says that he prepared the bomb made of 40 sticks of dynamite, put the sticks in the suit case. . . . He did not put dynamite either on the cars or on the boat, but told Crowley that he did.

At a later date, May 28 (1915), Crowley came and wanted another bomb prepared.

The Shinsei Maru was the ship which they looked for that Friday night, Crowley telling Smith that the bomb must be gotten off on the first string of cars off the wharf. . . . He says that Crowley left him and that after a time he drew the dynamite away; that he went to Crowley's hotel and deceived him in the belief that he had put a bomb on board the ship that night.

About the 29th of May, Saturday, Smith says they . . . (tried) to get a bomb into the cotton that the Hazel Dollar was loading and that he told Crowley that he had put the bomb in. Smith says he threw the dynamite away in a cesspool.

PULVERIZED FUEL COMBUSTION

By Frank C. Perkins.

THE use of pulverized coal is said to make practicable the highest efficiency obtainable in boiler operation. It makes coal burn like a gas, with a flame, the physical and chemical character of which is regulable—a flame that may be elongated or shortened, thus placing the zone of highest temperature where needed; a flame that may be made oxidizing, reducing or neutral, as occasion may require.

The coal is burned as pulverized, thus there is no storage of the powder with its attendant hazard. Artificial drying of the coal is not necessary if the supply be sheltered from rain and snow. Where the pulverizer is used, it is wholly a furnace question whether a dryer should be installed. It is not at all a pulverizing or storage question. The labor is reduced to a minimum and slack coal at low cost yields it last b.t.u.

The pulverizer described herewith approaches the subject of coal burning from the theoretical side, and, therefore, pulverizes the coal to an impalpable powder, and surrounds each of its minute particles with the amount of air which will furnish just the required oxygen. The fineness of the pulverization may be regulated by attention to the dampers which control the movement axially of the air within the machine. If that movement is slow, the centrifugal force keeps all coarse particles at the periphery, and they are drawn from one chamber to the next only as they become reduced to such fineness as to permit the axial current to overcome the centrifugal force, but if the movement axially is rapid, it in part overcomes centrifugal force and draws through the machine a coarser grade of material. The pulverizer utilizes air separation on thoroughly scientific lines. Powdered coal and air in regulable proportions are intimately mixed in the pulverizer, and the mixture reaches the furnace instantly it leaves the pulverizer.

The mixing operation commences at the feed end of the pulverizer, where coal and air enter together and the pulverizing and the mixing go on together until the mixture leaves the pulverizer having the appearance of a cloud of smoke. This impalpable powder, with its theoretical requirement of air, is conducted through a suitable pipe directly from the pulveriser to the furnace. There is no coal pulverized except for instant use. Every minute particle of coal is in the furnace and ablaze within one second from the time it leaves the pulverizer, and within one additional second is completely consumed. In a majority of cases the time is less than one-half a second in each case.

A condition is, therefore, created and maintained, in which each particle of coal is separated from every other particle when it enters the furnace, and no opportunity is offered for the powder to pack or for the particles to adhere one to another, but each particle is enveloped in air and, therefore, in contact with the oxygen necessary for combustion. Thus, this system is emancipated from not only the dryer, but the powdered coal conveyer apparatus, the storage bins, the mixing chambers and the feeding mechanisms with the power units required for the several operations. There is nothing between the coal bunker and the furnace except the pulverizer, its motor, and a plain pipe connection. When the mixture of coal and air reaches the furnace combustion proceeds with great rapidity, with no smoke, no carbon in the ash, no CO in the flue gases, and only a trace of O, and no appreciable excess air is admitted to reduce the temperature of the products of combustion.

There is no opening of doors, no intermittent firing, no banked fires, no delay in meeting a sudden overload. The pulverizer consists of three or more interiorly communicating chamber of successively increasing diameters, in which revolve paddles on arms of correspondingly increasing lengths. The separate chambers are, in fact, separate pulverizers on a single shaft, each succeeding pulverizer having greater diameter and, therefore, greater speed at its periphery and greater power for fine grinding, each receiving and treating the product of the preceding chamber and passing it on to the succeeding chamber for still further reduction.

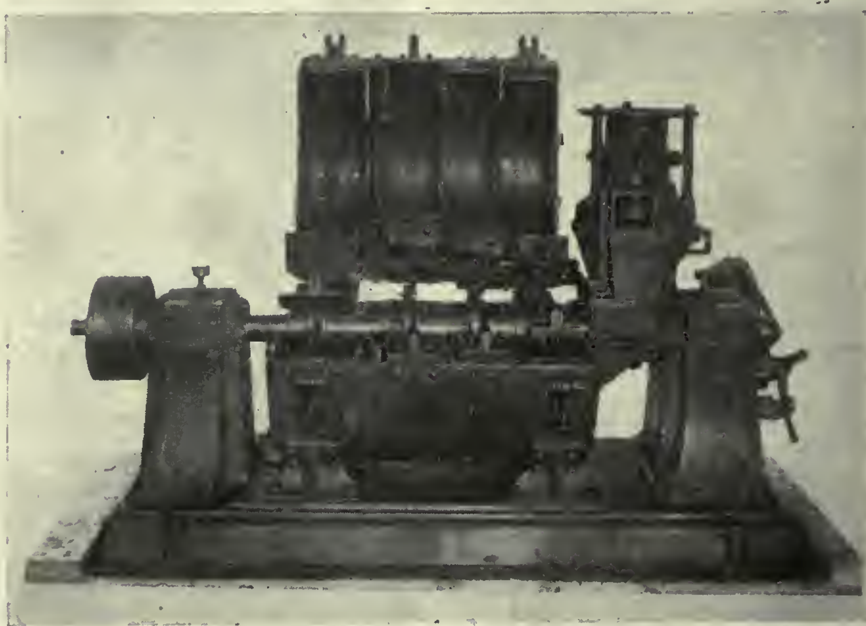
An additional chamber contains a fan, the function of which is to draw the finely pulverized material successively from one chamber to the next, and finally, to deliver it through a pipe connection to the furnace under the impetus of a forced draft. The separate pulverizers and fan are enclosed in one steel cylinder. A regulable feed mechanism accurately controls, and at the will of the operator varies the quantity of coal admitted to and delivered by the machine.

The feed mechanism is exact and uniform in its operation, and is easily adjusted to meet even minute variations in the fuel requirement. Two inlets in the feed mechanism admit the air required for fine grinding. An auxiliary inlet between the last work chamber and the fan, controlled by a damper, admits such additional air as is required for combustion. The air dampers with the feed mechanism give perfect regulation of the flame within a wide range.

Construction

The pulverizer runs at constant speed and the operator's attention and work is limited to observation of his fire and regulation of the feed mechanism. One operator can attend to a number of installations. The pulverizer is dust-proof, and is arranged for easy repair to the parts susceptible to wear, the cost of which is small. The paddles, which are subject to the greatest wear, are of cast manganese steel, heat-treated for ductility and to resist abrasion and are reversible. The shaft is of 40 carbon open hearth steel.

The spiders are in one piece, cut from ½-inch steel plate, and are bolted to cast iron hubs with shearing bolts of a size to withstand ordinary strain, but to shear with extraordinary and unusual strains. The linings are of steel plate, and there is a relief opening in the bottom of the first chamber for the automatic removal of any iron or other metal that may accidentally enter the machine.



COAL CRUSHER AND PULVERIZER.

This equipment may be located either in front of the furnace or at either side, or above or below, and may be set with the discharge opening toward the furnace or away from it, or in any intermediate position as convenience may dictate, and the drive may be by belt or by direct connected electric motor. The connection between the pulverizer and the furnace is usually a galvanized iron pipe from the pulverizer discharge to the furnace. No additional feeding or mixing apparatus could serve any useful purpose, for the powdered coal and air are intimately mixed in the pulverizer. The furnace end of the discharge pipe is made of such size and shape as the furnace condition requires.

Engineering at the Canadian Exhibition

Single Purpose and Standard Machines Are Shown — More Adequate Facilities Are Needed—Supply Houses and Transmission Specialists Also Have Interesting Exhibits on View

THE present trend of engineering manufacture is shown in the exhibits featured by the various manufacturers in Machinery Hall. Munition machinery, while still in evidence, is giving place to standard lines adapted to the more peaceful work expected as a result of after-war conditions. The exhibits compare favorably with those of former years, and granting more adequate facilities for exhibitors after the war, this portion of the exhibition should become one of the most interesting and attractive features on the grounds.

AS in past years the inadequate accommodation provided by machinery hall is very much in evidence, many exhibitors declaring their dissatisfaction with existing conditions and evincing a desire for better service and more room in which to display the various phases of mechanical industry. It is hardly just that the industrial arts, so all important in Canadian life and so essential to the successful prosecution of the war, should be limited by the accommodations provided while exhibits of a nature placing them in the non-essential category are given much more prominence in the many buildings of the Fair. It is hardly to be expected that any change for the better can take place until after peace is declared, but consideration should be given to the problem and the machinery exhibits given a location and buildings on the grounds where they would command the attention their importance deserves.

Cutting Tools

Recent progress in the field of cutting tools and metals is recorded in the display of Stellite by the Deloro Smelting and Refining Co. The makers of this well known cutting alloy have succeeded in perfecting methods by which formed tools of all shapes are readily cast and in such a manner that very little grinding or finishing is required. A display of welded cutters forms part of the exhibit, the cutters shown being stocking cutters used by the Hamilton

STELLITE FACED WELDED CUTTER BEFORE GRINDING

Gear Co. in operations on gear wheels. These welded cutters are formed of a soft steel centre on which the cutting edges of stellite are welded by the oxy-acetylene process. Built up cutters are also shown, the inserted blades of stellite being fastened to the steel centre by the usual methods. A recently discovered use for stellite is in the making of sand blast nozzles. These nozzles owing to the extreme hardness of the metal used usually last for about two weeks. This is an unusual length of time for nozzles of this purpose to last, the ordinary nozzle lasting for continuous work for about two hours.

Rough turning by the use of stellite is shown on an A. R. Williams Montreal lathe, six-inch shells being used. A Cisco lathe is also shown operating on cast iron.

The Cole Steam Trap

The effect of varying pressures and heads on the capacity of steam traps is clearly brought out by a working

COLE AUTOMATIC STEAM TRAP.

installation of the Cole automatic return trap. The trap used is of the high pressure type approved by the boiler inspection branch of the Department of Public Works; this trap is built to boiler specifications.

A typical double trap boiler feeding installation is also shown, draining both high and low pressure lines and returning the condensate from both as well as raw make-up water to the boiler. The balancing of return pressures by the use of high and low pressure traps is well shown by this exhibit. Cross-section models of the working parts of these traps are also on exhibit, one of which clearly shows the protector cage used on the steam valve, the disc being lifted into the protection afforded by a cage and removed from the paht of the steam, preventing its cutting by wire drawing.

Interesting literature is available at this booth dealing with various phases of power plant economy. Bulletin No. 7 treats of steam condensation, Bulletin 9 a reprint of an article appearing in *Power House*, by Wm. H. Rose, the representative, deals with the subject of automatic boiler feeding from the standpoint of economy compared to the use of feed pumps. Bulletin No. 11 is a publication of special interest to the plant or factory executive and treats of the steam plant as a factory which should be run on the same businesslike principles that govern factory management.

THE PNEUMATIC TOOL IN OPERATION.

Thor Pneumatic and Electric Tools

The Independent Pneumatic Tool Co., manufacturers of Thor tools, are represented by Mr. W. H. Rosevear, Canadian manager, and Mr. Gordon McCrea, Ontario manager. The various types of rivetting and chipping hammers and drills are shown in operation and an exhibit of the tools in sectional form shows the complete mechanism to advantage. The pneumatic drills are equipped with Corliss valves, roller bearings and pressed vanadium steel pistons and connecting rods. This latter construction results in very light yet strong working parts and removes much of the inertia load inseparable from reciprocating mechanisms.

Toledo Scales

Accuracy and dependability coupled with ease in manipulation mark the scales exhibited by the Toledo Scale Co., 335 Yonge St., Toronto, of whom C. H. Collins is the Canadian manager and W. E. Davies the Ontario special representative. The industrial scales manufactured by this company are on exhibit in machinery hall and the most interesting feature of the exhibit is the industrial 12,000-pound capacity, unit weight built in type dormant scale.

This scale has a large easily read dial graduated up to 2,000 pounds, and when heavier weights are to be weighed instead of adding weights to the beam by hand an automatic mechanism places the weights on the beam pan by the shifting of a lever. At the same time the weight in pounds which is to be added to the dial indications appears in large characters in a window on the dial face. This unit weight arrangement adds greatly to the sensitiveness of the scale, the dial indications reading to as small a figure for heavy loads as for small. Tare beams are also provided and if for any reason hand weighing is desired it is accomplished by unhooking the dial mechanism, placing a weight in an auxiliary scale pan and proceeding as usual in hand weighing.

The scale platform is not limited in size to any one set of fixed dimensions but may readily be adapted to any conditions likely to be encountered in practice. Industrial tracks may readily be used.

Baines and Peckover

The present developments in reinforced concrete construction for factory buildings and more especially the adaptation of this constructional material to the building of ships lend interest to the exhibit of concrete reinforcement featured by Baines and Peckover. A model of steps in concrete shows the steel reinforcement and the tie chain and bar ties to advantage. These steps also display to advantage another building material handled by this firm. Feralun anti-slip treads are incorporated in the steps and a Feralun plate and coal hole cover are shown at the bottom.

This product is formed by the integral incorporation of an abrasive substance into the iron body of the tread and the resulting surface prevents one of the most common causes of accidents, that of falling on stairs and the slipping on smooth cast iron surfaces. Steel-crete expanded metal machine guards are also featured, together with an excellent display of Triumph Suberb high speed tool steel, cold drawn and nickel steel bars.

S K F Ball Bearings

The Canadian S K F Co. of Toronto and Montreal, represented by Gordon Janes, H. N. Trumbull, A. G. Webster, H. Brown and Drummond Giles have an attractive display of S K F self-aligning ball-bearings and Hess-Bright ball and thrust bearings. Ball bearing hanger and bent shaft working models are seen in operation and loaded friction demonstration apparatus shows the comparative ease in operation of the ball-bearing over the ordinary journal. Numerous photographs, display literature, showing applications of ball-bearings, and the display of "Atlas" chrome alloy steel balls in various stages of manufacture form interesting features of the exhibit.

Boiler Protector Co.

The National Boiler Protector Company, 24 Lombard Building, have an exhibit showing their girth seam patch and blow-off pipe protectors, together with short elbows and long sleeves which go with the blow-off pipe protector. The exhibit consists of a complete girth seam protector attached to boiler plate and a complete blow-off pipe protector together with the separate units that go to make up the two items.

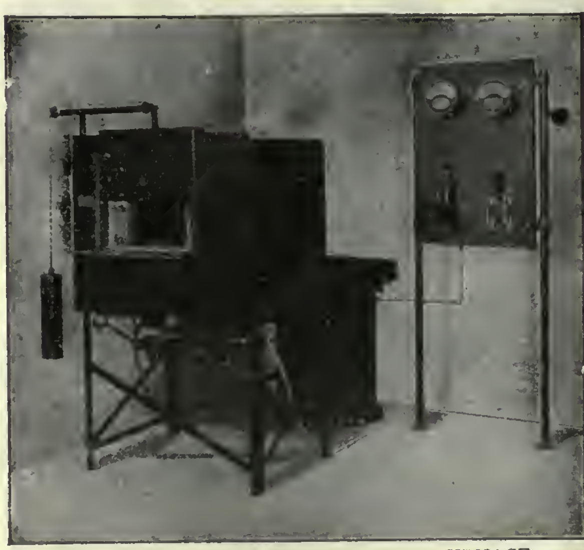
Oil Burners

The National Oil Burners and Systems Limited, Lombard Building, have a display of oil burners adaptable to high and low pressure boilers. These oil burners have been tried out for the last nine months and have given extremely good satisfaction on both boilers for the generation of steam and on metallurgical work such as case hardening furnaces, heat treating furnaces, and forging furnaces.

Hoskins Electric Furnaces

The increasing appreciation of the benefits of heat treatment and accurate temperature control is reflected in the exhibit of Hiram Walker and Sons, Walkerville, who are handling the well-known Hoskins line of electric and gas furnaces, pyrometers, pyrometer couples and laboratory apparatus. Their product also includes a unique product, Nichroloy, a non-ferrous alloy which possesses marked non-corrosive properties, especially under the influence of heat. These properties are due to the high melting point of chromium combined with the high resistance of nickel to oxidation. This metal does not soften appreciably under heat as does cast iron and has a life approximately 40 times as long. Applications already proven include carbonizing boxes, cyanide crucibles, lead pots, barium pots, etc.

It is of especial interest to know that this alloy is made in Canada, together with a special type of carbon resistance furnace which is also displayed. Its simplicity of construction and efficiency of operation render it particularly adapted to high temperature work.



HOSKIN ELECTRIC RESISTANCE FURNACE FOR THE HEAT TREATING OF STEEL

HAMMER IN OPERATION. CLEAVELAND CHIPPING

Pratt and Whitney

Special appeal is made to the skilled mechanic and fine tool maker by the Pratt & Whitney exhibit of Canadian-made cutters, reamers, taps, drills, shell tools and special articles of a similar nature. The prestige attached to the name is well upheld by this exhibit, which is convincing evidence of the possibility of producing such goods on a commercial scale within the Dominion.

Transmission Equipment

Transmission equipment and apparatus is featured by the Dodge line, one of the items of interest being an exhibit showing their wood pulley in different stages of construction; from the plain board of selected lumber to the perfectly finished wood-split pulley seen on the shafting.

Pneumatic Tools

The Cleveland Pneumatic Tool Co. of Canada, Ltd., are showing a complete line of pneumatic tools and appliances such as are used extensively in the shipyards of Canada and the United States. The new pocket in head riveting hammer shown by this firm has an improved valve arrangement which adds greatly to the effectiveness of the hammer and the pocket in head construction forms a reservoir for compressed air which increases the force of the blow. A line of compressed air drills, accessories and hose is also shown.

The Perfect Machinery Co.

The Perfect Machinery Co., Galt, have a display of gear-driven and sensitive drills, a full line of grinders equipped with both machine guards and exhaust hoods. Three types of hacksaws for various purposes are shown and an 18 inch double back geared quick change gear are shown. 12-inch and 14-inch lathes suitable for garage or engine work are also shown. These lathes are an example of accurate high grade workmanship and convenient design. It is a very convenient tool for machine shops, experimental shops, trade schools and manufacturing opticians. These lathes are made with 12 and 14-inch swing and a 6-foot bed.

Garlock-Walker Machinery Co.

The Garlock-Walker Co. have a representative display of woodworking and machine tools, band saws, surfacer saw filing machine, cutting off saws forming part of the exhibit. A Lodge and Shipley 20-inch selective head engine lathe is shown in operation. This lathe has been designed for quantity production and the mechanical arrangement of the operating details leave little to be desired in the way of ease in operation. A Leisy-Patton threading and screw machine is also shown.

Electric Motors

Jones and Moore have a representative display of their various motors and generators and of the American shoe machine for which they are the agents. This firm handles a large stock of Century motors for all conditions of service.

Belting

The Main Belting Co. of Canada, S. R. Walsh representative, have a display of Leviathan and Anaconda belts adapted both for power transmission and conveyor purposes. These belts are specially impregnated when required to handle extremely hot or abrasive materials and in combination with the conveyor rolls manufactured by the same firm give excellent service under severe conditions. A sample of belting taken from a belt 80 inches wide and of 300 feet run forms an interesting part of the exhibit. Belt fastenings, dressings and other materials used in the transmission of power are also shown.

L'AIR LIQUIDE SOCIETY

A standard line of oxy-acetylene welding and cutting apparatus is being shown by L'air Liquide Society. Examples are shown of manufactured articles fabricated by the welding process, among which are sheet steel welded transformer cases by the Packard Electric Co., bread racks by the Brantford Oven and Rack Co., steel furniture by the Office Specialty Co. and high pressure boiler by Damp Bros.

The manufacture of welded acetylene cylinders is being carried on and the welding demonstration of the soldiers' Civil Re-establishment exhibition is using apparatus of this company's make. A school for the instruction of the returned soldier in the art of welding and cutting metals is being carried on at the company's plant, the soldier being given a six months' course at the expense of the company for the materials used and the instruction given.

Canada Machinery Corporation

A fine exhibit of iron and wood-working tools is being shown by the Canada Machinery Corporation, a 26 in. 12 ft. bed heavy duty lathe with quick change gears is exhibited and a recent design is seen in a 20 in. crank shaper with power down feed to head. The drill presses comprise 20 in. back geared press and plain lever drill presses.

In the wood-working machinery branch are seen the new straight edging and jointing saw; a new tool on the Canadian market and which is being operated; a variety saw with band and a 6 in. four-sided sticker. This exhibit of made in Canada machinery is under the charge of Mr. King, who has the assistance of P. D. Burton, assisted by Mr. Preston and H. O'Donnel.

Canadian Ice Machine Co.

The Canadian Ice Machine Co. have an excellent exhibit of refrigerating supplies and materials; fittings, ammonia, calcium, chloride and other supplies being featured. This firm are the manufacturers of the York refrigerating systems and compressors, installations being made from ¼ ton up in the direct expansion, absorption or CO_2 systems, the latter being popular and of considerable adaptability for hospital and marine work.

The Carter Welding Co.

The Carter Welding Co. are showing the Beck-Todd spacing machine, a Canadian invention used for the elimination of recuts in nicking shell steel. This machine, by a suitable mechanism, divides the bar steel into a desired number of pieces, all of equal length, no matter what the length of the steel bar may be. By achieving this result no recutting of the last billet is necessary to eliminate a short end. This machine finds its greatest application in the nicking of shell steel by the oxy-acetylene torch.

The oxygraph is shown in operation cutting test pieces out of 6 in. shell billets at a time rate of about two minutes per test piece, the cost of the operation being about seven cents.

High pressure acetylene generators are on exhibition, acetylene being generated at from 50 to 200 lbs. pressure as may be desired. In addition to a complete line of Davis-Bournonville cutting and welding torches a standard government emergency outfit is shown. This outfit of cutting and welding torches is enclosed in a bullet deflecting case and large numbers are being used with the American army in France.

A water-cooled torch for heavy work is shown, the tip being water jacketed.

Belt Dressing

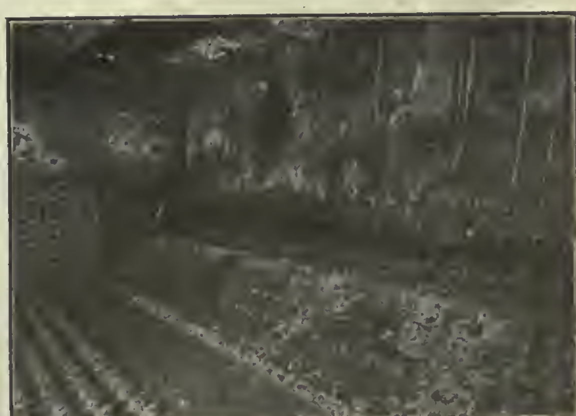
The present exhibition marks the tenth year for the Cling Surface Co. at Machinery Hall. The saving in power produced by this belt dressing and the longer life of the treated belt are of particular importance at the present time in view of the wide-spread necessity for the economical use of power. Aside from the economy effected in power the preservation and water-proofing of the belts, the saving in lacing and the lowering of the friction load consequent upon the permissible slackness of the belts are desirable features. The belt driving the lathe demonstrating Stellite has been treated with Cling-Surface. Mr. J. B. Faatz is the representative of the Cling Surface Co.

Mechanical Rubber Goods

The Dunlop Tire and Rubber Co. are exhibiting their mechanical rubber goods for the first time in Machinery Hall, Mr. H. C. Austen being the representative in charge. Engineers' supplies and rubber belting are featured.

A large demand has been created for Gibraltar Red friction covered belt, consequent upon the expansion of the munitions business. This belt is made of heavy canvas duck impregnated with a very strong friction. Valve discs hose for industrial purposes and the Gibraltar Red pneumatic tool hose, made to meet the demands of the shipbuilding industry, comprise a portion of the exhibit.

BOILER PREPARED FOR WELDING



BOILER AFTER WELD IS COMPLETED.

A. R. Williams Co.

The A. R. Williams Co. have an excellent exhibit of iron and woodworking tools. A variety of drill presses including bench drills is shown and A. R. Williams, Montreal lathes, and a Cisco lathe are being used to demonstrate the use of Stellite in the exhibit of the Deloro Smelting and Refining Co.

Marine interests are well represented in a line of marine gas and pumping engines and the wood working tools shown are particularly applicable to the needs of the marine industry. A 36 in. Preston bandsaw and 24 in. Eclipse planer are on exhibit together with a variety of tilting saw tables and a self feed ripsaw made by the Preston Machinery Co. The needs of the manual training schools for instruction lathes are met by a lathe also by the above firm with an attached motor. A Preston two-spindle shaper is shown which is self contained, the double countershaft and motor being installed in the base of the machine.

In the metal working department a universal Le Blond milling machine is shown and a demonstration is being given of the Racine metal-cutting saw; this machcine owing its excellent cutting abilities and economical use of saws to the arrangement whereby the saw is raised from the work during the return stroke. The excellent exhibit is under the care of Mr. Cronk and the arrangement is due to him. In connection with the A. R. Williams' exhibit a demonstration of the tungsten spark plug is arranged, the wearing qualities of the plug being due to the extremely hard and refractory material of which the points are made.

Canadian Consolidated Rubber Co.

One of the most interesting industrial processes is the turning of crude rubber received from the plantations and forests into the manifold articles met with in daily life and anything showing the various forms rubber assumes during its progress step by step through the factory is unusually interesting to anyone. The Canadian Consolidated Rubber Co. are showing an exhibit of this kind in the process building, each form assumed by the rubber being shown from the wild and plantation rubbers to the finished article.

This company are also showing an excellent exhibit of their mechanical rubber goods, featuring their engineers' supplies and belts. The Dominion belt shown is a belt made with extra strong friction and is designed for severe service both in the transmission of power and in conveying operations.

The Chapman Double Ball Bearing Co.

This company has, as usual, a most attractive exhibit of the various lines manufactured by them in the center row at Machinery Hall.

In addition to their ball-bearing shaft hangers used in the line shafting the exhibit includes bearings for all sizes of shafting up to six inches; also annular and thrust bearings for machinery, automobiles and trucks. This latter line is a new development for the company and supplies the Canadian market with a made-in-Canada product.

The various products are artistically arranged on pillars mounted on large turn table ball bearings which have been manufactured for the Grand Trunk Railway and as an illustration of the extremely light friction load of the ball bearings the turn tables and a length of ball bearing equipped shafting are turned by means of a fractional horsepower motor through thread belting.

The excellent qualities of these bearings has enabled the company to enter the export field and the United States market is supplied by their Buffalo plant.

Several sizes of the Universal truck for industrial and shop use are also shown.

Prest-O-Lite Co.

The many uses to which oxy-acetylene welding is put are well illustrated in the many types of apparatus shown in the Prest-O-Lite display. The exhibit comprises all their various welding and cutting torches, including a small instrument for jewellers' and dentists' use.

PREST-O-LITE EQUIPMENT BEING USED IN WELDING OPERATION.

Particular attention is drawn to the use of dissolved acetylene for welding purposes and the convenience of this apparatus for lighting large areas where construction work is being carried on is especially commended.

D. K. McLaren, Limited

This company represented by Mr. W. S. Hamilton, sales manager, are exhibiting their line of single and double leather beltings, together with the waterproof varieties. Canvas balata impregnated belting is also shown. D. K. Wood split pulleys, which are shown in various sizes, are constructed of carefully selected materials, air dried for months and kiln dried before being made up. The spokes are built up of white oak carefully secured into the rim.

The Philips pressed steel split pulley, for which this firm are the sole Canadian selling agents, is another line which has met with a wide sale. The hub is made of cast iron, bored to a perfect fit and is clamped by four hub bolts. The spider is heavy sheet steel and is riveted to the hub. The rim formed from sheet steel is flanged in on both edges the sheet extending back to the center where it is bent at right angles and forms a central rib to which the spider is riveted.

An interesting set of photographs of a leather belt recently completed for main drive purposes is on view. This belt is unusual in that it is made of four plies, the dimensions of the belt being 110 ft. x 24 in. width. The belt is waterproofed.

Mill supplies for the carding, spinning, weaving and hosiery trades are also featured.

Dodge Manufacturing Co.

This company have an excellent display of standard transmission machinery exhibiting their shaft hangers, conveying apparatus, wood and iron split pulleys. The various steps in the manufacture of the wood split pulley are shown. The method of jointing segments by means of dove-tailed glued joints, the building up of the laminations into the completed rim and the method of attaching the pulley arms to the rim being clearly shown. The construction adopted permits the turning of the inside of the rim. The rim is finished with a special filler and varnish which secure a very durable surface and one which reduces belt slip to a minimum.

The West Toronto Foundry

Eclipse shaking and dumping grater are being shown by this firm in Machinery Hall, the ease of operation and the fuel economy resulting from their use being especially commendable.

The Mac 8 syphon for isolated sewage disposal plants is another product shown that finds a particular application on farms or other places where septic tanks are installed. No moving parts are used, the intermittent action of the syphon depending on an air seal.

Thomas J. Brown has been reappointed to his former position as general superintendent of the Sydney Mines of the Nova Scotia Steel and Coal Co. This appointment was one of the first official acts of D. H. McDougall as president of the Nova Scotia Steel and Coal Co. His new duties will involve the management of the steel plant in addition to both collieries. It is understood that Thomas H. Hartigan will also resume his former position at the Scotia works as assistant to Mr. Brown.

Representation of Screw Threads and Dimensioning

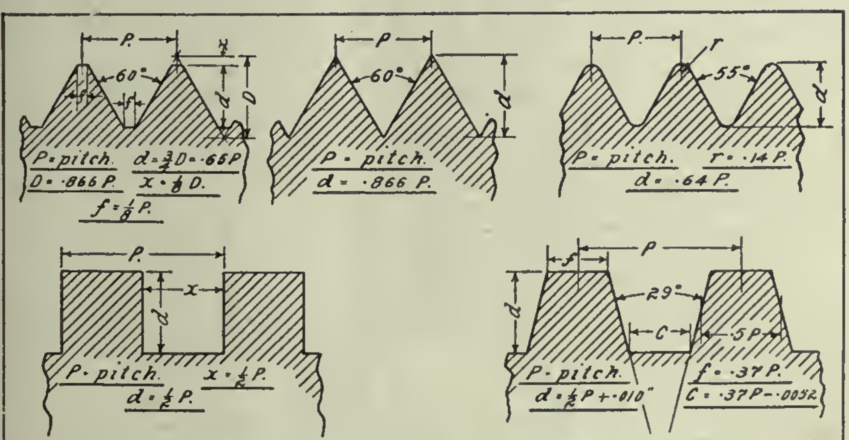
Proper Delineation of Screw Threads is an Important Detail in Connection With Mechanical Drawing, and Accurate Dimensions Are Very Essential

REPRESENTATION of screw threads in mechanical drawings is a subject worthy of rather detailed consideration. It is seldom that a mechanical drawing does not show thread of some sort or other. If a man who makes many drawings would reckon the number of screw threads which he renders in a year, he would find the value much greater than would be anticipated. It is, therefore, extremely desirable, both from the standpoint of good economics and good appearance, to learn at the start the best methods of showing screw threads on drawings.

The applications of the screw threads of the different types will not be considered in detail herein. That is, it is not proposed to discuss exhaustively the relative merits of the threads of the different designs. Treatises on machine design cover this subject. It will be assumed that the reader understands something of the applications of the different threads. Hence, in the following discussion, the methods of delineating will be given primary consideration.

Screw Thread Forms

The different forms of screw threads which are in common use are shown in Figs. 1 to 5 inclusive. Fig. 6 defines graphically the names of the parts of a thread. The pitch, P ((Fig. 6), is equal to 1 ÷ (number of threads per inch). For example, a 1-2 pitch on a screw means that it has 12 threads per inch. The ¼ pitch shown in Fig. 6 means that that screw has four threads per inch. Some of the important pictorial characteristics of the screw threads of the different types will be discussed in sections which follow.



FIGS. 1-5—FORMS OF THREADS IN GENERAL USE.

The United States standard thread (Fig. 1) is the one which is used much more frequently than any of the others and is, so it is ordinarily understood, the type to be used unless some other is definitely specified. This form is also known as the Franklin Institute standard and the Sellers standard. As detailed in Fig. 1, the sides of the groove cut from the material to form the thread are inclined to one another at an angle of 60 degrees. The crest of the thread is cut off for a distance equal to one-eighth of the height and the bottom or root is filled in for this distance. This flattening of the crest and root increases the strength of the thread and renders it less likely to become mutilated by rough treatment. While a true U. S. standard thread is actually turned with a flattened crest and root as shown in Fig. 1, these flat surfaces are seldom if ever shown on mechanical drawings.

The "Sharp" V thread is detailed in Fig. 2. The only difference between this and the U. S. standard is that the crest and root are not flattened. In spite of the fact that the U. S. standard is the better type from every standpoint, the "sharp" V thread is utilized frequently, although it is probable that its applications are continually decreasing in number.

The Square thread (Fig. 3) has all of its faces at right angles to one another. This type of threads finds its principal application in the transmission of motion or force for which purposes it is better adapted than are the V threads. Examples of applications of the square thread may be found on the feed screws of metal turning lathes and on the screw of an ordinary letter press. The "Acme" thread (Fig. 4) and the "Whitworth" thread (Fig. 5) are used occasionally.

Briggs pipe threads (Fig. 7) are standard in this country for threading the ends of pipes which screw into tapped holes or couplings. These threads may be represented by the conventional method detailed in Fig. 7 at I. Note that the parallel lines representing the crest and the root of the threads are not inclined at an angle but are horizontal. Also note that each line does *not* extend entirely across the pipe. On large drawings or where for some reason the time

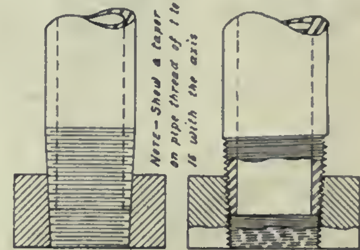


FIG. 7—PIPE THREAD.

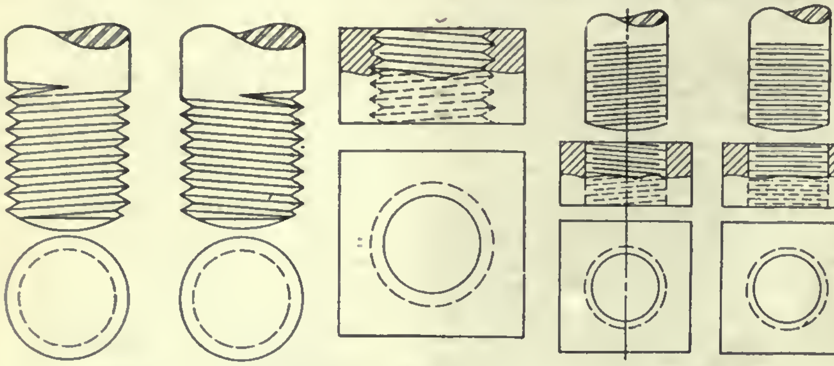
expenditure involved is justified Briggs pipe threads can be rendered as at II. in Fig. 7. It is seldom, however, that such a detailed picture is necessary on a mechanical drawing. It should be noted particularly that the pipe thread tapers so that as the thread is screwed into a coupling or tapped hole it wedges itself tightly. This taper should be shown on the drawing if it is large enough to warrant it.

Right-hand threads and left-hand threads differ from one another in that an object which is threaded with a right-hand thread moves longitudinally away from the person who is turning it when it is turned in the direction in which the hands of a clock rotate; that is, in a clockwise direction. A left-hand thread moves away when it is turned in a counterclockwise direction. The applications of left-hand threads are relatively very few. Where they occur on a drawing they should be marked distinctly LH, and the rendering of the thread should also, in accordance with one of the methods to be described, be such that it will indicate that it is a left-hand thread. Note that the lines representing a right-hand thread (assuming that the threaded rod lies in a vertical position) slope up from left to right as shown in Fig. 8, while the lines of a left-hand thread (Fig. 9) slope in the opposite direction.

Thread Representation

The methods of representing V threads will now be considered. When the diameter of a bolt or the diameter of the hole in a nut, as it is plotted on the sheet, scales more than 1 inch, the methods illustrated in Figs. 8 and 10 may be employed on drawings where attractive appearance is an important factor. Where the diameter (as it scales on the sheet) is less than 1 inch and greater than 3/16 inch, the method of Fig. 11 or 12 is employed. In fact, these methods (Figs. 11 and 12) are ordinarily used on shop drawings even where the diameter of the threaded part scales greater than 1 inch. The difference between the rendering of Figs. 11 and 12 is that in Fig. 11 the thread lines are inclined, while in Fig. 12 they are horizontal. Where threaded objects, which scale less than 3/16 inch in diameter on the sheet, are to be shown, the delineation suggested in Fig. 13 may be utilized. With this method, the thread lines do not extend entirely across the width of the object. A threaded rod with a tapped hole in its end can often be shown effectively in section, as detailed in Fig. 14.



FIGS. 8-12--CONVENTIONAL METHODS OF SHOWING THEADS.

The double thread is one which is really a combination of two threads on one screw (Fig. 15). A double-threaded bolt advances twice as far per revolution as does a similar single-threaded bolt. See also Fig. 22 for a double right-hand square thread.

In drawing pictures of V threads like that of Fig. 8 for example, there is a certain procedure (Fig. 16) which should be followed. At A is represented the first step. Note that the measurements for the thread lines are made only along one side of the rectangle upon which the thread lines are to be shown. Then by sliding a triangle along a straight-edge which has been sloped slightly, the parallel lines representing the thread crests can be drawn. The slope, as shown at A, of each crest line equals ½ of the pitch for a single thread. The next step is (B) to draw lines of 60 degrees in one direction from the end of each of the thread crest lines. Next, as at C, a 60-degree line is drawn in the other direction from the end of each thread crest line. Then to complete the screw, the lines representing the roots of the threads are drawn in.

The representation of square threads will now be considered. The actual appearance of the square thread bolt and nut is that given in Figs. 17 and 18. Two helices, one representing the outside face edge and the other the root of the thread, are required in this pictorial representation if it is to be rendered accurately. However, it is seldom that such procedure is desirable as the conventional rendering of Figs. 19 and 20 conveys the idea adequately. A left hand square thread can be rendered as diagrammed in Fig. 21 and double and triple right-hand square threads as in Figs. 22 and 23 respectively.

The representation of the Acme thread is given in detail in Fig. 24. A comparison of this with the data given in Fig. 4 will indicate why the representation of Fig. 24 is desirable. It is to be understood that the nut of Fig. 24 is threaded for part of its length for a right-hand thread and for the remainder of its length for a left-hand thread.

Importance of Dimensions

The dimensions are probably the most important element of a working drawing because without them the sheet would, obviously, be useless. A roughly-executed sketch, if properly dimensioned, will convey its story effectively. But if the most deftly-executed drawing is improperly dimensioned, it will be worthless and may make no end of trouble.

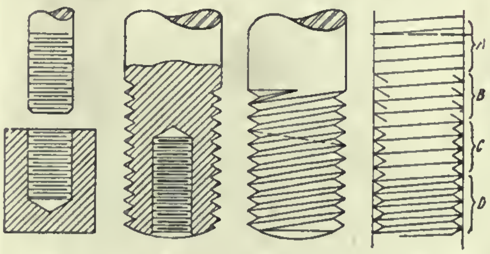


FIG. 13. FIG. 14. FIG. 15. FIG. 16.
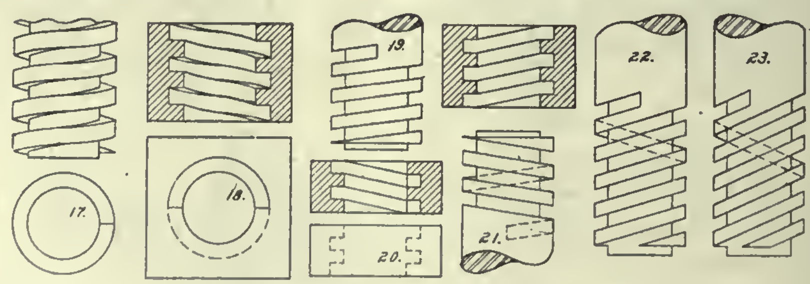
CONVENTIONAL METHOD OF ILLUSTRATING THREADS.

As used here, the term "dimension" comprehends not only the digits or figures indicating inches or other units of measurement, but also the arrow-heads (sometimes called barbs), the lines in which the dimensions are inserted and also frequently some notation. By notation is meant any symbol or sign which may be required to denote certain quantities. Examples of such symbols are: ′ (ft. or min.), ″ (in. or sec.), ° (deg.), etc., etc. Dimensions should be so placed that there can be no confusion in interpreting their meanings. Unfortunately this obvious rule is often violated. It is imperative that the figures be of such size and so located that they can be easily read. The arrow heads should be carefully placed so that there can be no mistake as to the extent of the dimension. Furthermore, the outline of the drawing should not be "marred" by any dimension. That is, no figure should touch or intersect the outline of the object. The dimension lines should be light so that there will be great contrast between the outline and the dimension lines, the outline lines being much more prominent. In general, it is desirable where possible to place the dimensions outside of the views. Opinion differs as to the most desirable form of arrowhead. The long slim form shown in Fig. 25 is preferred by some draftsmen and is probably as good as any, although a number of organizations insist on the use of an arrow-head which is "short and fat" resembling the Roman letter V.

Good and bad practice in dimensioning are pictured graphically in Figs. 25 and 26. From a superficial examination it is apparent that the drawing of Fig. 26 is much easier to "read" than is that of Fig. 25, although both of them show the same object and the same dimensions. "The List of Errors" given under Fig. 25 recites the features in which that illustration is incorrect. The number preceding each item in the list corresponds to an identification number located within a circle in Fig. 25.

Rules which should be observed in dimensioning drawings are given in the following list. While this is not complete, it certainly includes the more important cautions.

1. The dimension should represent the finished size of the piece.
2. The dimension should be written so as to be read from the bottom or right side of the sheet. Some drafting rooms follow the practice of writing all dimensions horizontally.
3. The figures of a dimension should when convenient be placed in a space near the centre of the dimension line.
4. The figures should be placed so that the line, if extended, would pass through the centre of them.
5. Fractions are to be made with a horizontal line between numerator and denominator. This division mark is to be made free-hand. The fraction should be about one and one-half times as high as the whole numbers, as shown in the example of Fig. 27a.
6. In general, give dimensions in



FIGS. 17-23—REPRESENTATION OF SQUARE THREADS.

inches up to 2 feet—over 2 feet, write 2 ft. 3" or 2' 3". The form 2 ft. 3" is the surest method and is to be recommended. 36-½ in. should be written 3 ft. ½".

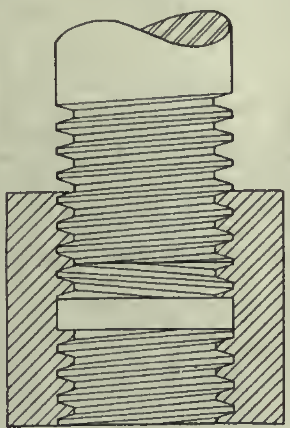


FIG. 24—THE ACME THREAD.

7. Make figures large enough to be read easily—distinctly plain and open.

8. The extension lines between which the dimension is placed should be a light line extending from corners, etc., between which the distance is desired. The extension line should not touch the object being dimensioned—leave space of 1/32" as in Fig. 27b.

9. A series of dimensions should be given in a straight line—not staggered. (See Fig. 27c and d respectively.)

10. With each series of dimensions, especially if they altogether total to the size of object, there should be given a corresponding over-all dimension.

11. It is well where possible to place dimensions between views. They are easily found there.

12. It is bad policy to repeat a dimension in two or more views; it might sometime be changed in one view and neglected in others.

13. When a circle is complete, the diameter is the better dimension to give. Radii should be given only for arcs.

14. When the diameter of a circle is given across the circle, the dimension line must pass through the centre of the circle.

15. The dimension of the radius of an arc must have the dimension line extending toward the pivot centre of the arc. (Fig. 27e, f, and g).

16. The arrow-head is on the end touching the curve—never on each end of the radius.

17. When a circular view is omitted, the diameter should be accompanied by "Dia." or "D". (Fig. 27h and i).

18. Never allow a dimension line to extend along a centre line.

19. Never allow a figure of the dimension to touch a line of the drawing.

20. Do not place a dimension on cross-hatching unless necessary. If necessary leave cross-hatching out around the figures. (Fig. 27j).

21. Dimensions should not be given between invisible outlines, since these lines are usually uncertain.

22. Do not crowd dimensions—they become confusing.

23. Never show a finished surface located from a rough cast surface.

24. In contemplated objects it is often advisable to give dimensions from centre lines.

25. Select dimensions so that the shop man will not have to add or subtract. He may make a mistake.

26. If it is possible to locate a required point from two finished surfaces, or centre lines, do so in preference to giving an angular dimension.

27. If too little room is allowed between extension lines for arrow-heads and figures, the arrow-heads should be placed on the outside of the extension line, or the figures may be placed outside.

28. All dimensions should be placed where they may be quickly and readily found.

29. The figures should be placed where they may be easily erased without disturbing the other lines of the drawing or where they may be duplicated with correction. (Fig. 27k).

30. Usually the scale of the drawing should be placed on the sheet.

31. Where very close work is required, the values of the limit dimensions should be decimals indicating the exact dimension or limits between which the work must caliper. (Fig. 271, n and m). (Refer to Sect. following on limits).

32. When a dimension is indicated by a leader, usually the leader ends with a half-arrow. The leader should be made mechanically, barb free-hand. (Fig. 27o and p).

33. The leader should be drawn in such a direction that the dimension or note may be horizontal or vertical, never oblique. (Fig. 27q and r).

34. The figures and notes should be kept uniform in size. ⅛-inch high is good height for ordinary work for the digits.

35. Figures along a diameter or radius change direction on a line sloping 60 deg. to the left through the centre of the circle. (Fig. 27s).

36. Never write figures, print them.

37. When there is a group of dimensions the shortest should be inside, longest outside. (Fig. 27t).

38. Check over-all dimensions by computation as well as by scaling.

39. When dimensioning a tapered object give taper per foot of length.

40. When threaded pieces and tapped holes are dimensioned by giving the diameter, the dimensions may be given by giving the diameter and the number of threads per inch. (Fig. 27u and v).

Limits and Tolerance

The specification of limits becomes of great importance on modern mechanical drawings of parts. Frequently the

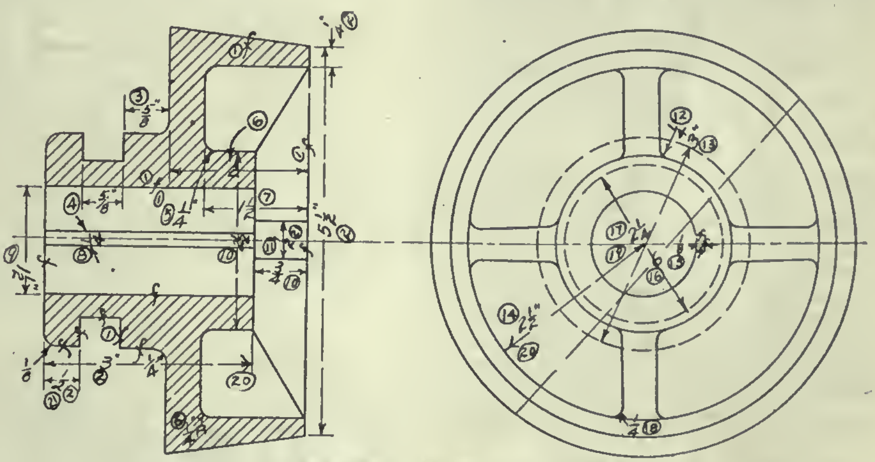

FIG. 25—INCORRECT METHOD OF DIMENSIONING.

LIST OF ERRORS IN DIMENSIONING FIG. 25.

1—Cross on "f" should be outside.
2—Extension line should not cross dimension line (Rule 37).
3—Measurement should not be taken from rough cast surface (Rule 23) and dimension too low (Rule 4).
4—Horizontal line should be between 5 and 8 (Rule 5).
5—End leader with half arrow (Rule 32). It would look better to extend in opposite direction.
6—Dimension should not be on cross hatching (Rule 20).
7—Awkward location.
8—Dimension line should be at right angles to boundaries under consideration.
9—Figures face wrong direction (Rule 2).
10—Figures crowded and touching outline (Rules 19 and 29).
11—Bad judgment in placing dimension. Should be on other view.
12—Radius line should point toward center (Rule 15).
13—Figure in poor location. Better near center (Rule 3). Dimension uncertain (Rule 21).
14—Dimension too high. Dimension line should be in line with center of fraction (Rule 4). Should be diameter (Rule 13).
15—Dimension line should not extend along center line (Rule 18).
16—Dimension line should pass through center of circle (Rule 14) and dimension misleading.
17—Figures should read with center line (Rules 4 and 35). Dimension uncertain (Rule 21).
18—Bad. Figures should not touch any line (Rule 19).
19—Arrow-head should be omitted (Rule 16).
20—Arrow-heads spread too much.
21—Written figures do not look well (Rule 36).

exact size of the parts which should fit together is not considered by the draftsman. For example, if a pulley is to run idle on a shaft, the diameter of the shaft may be specified as 1¼" and the hole in the pulley also as 1-¼". It is obvious, however, that if both the hole and the shaft are exactly 1-¼" the one cannot fit into the other, much less rotate on it without excessive friction. In fact, there should be a clearance of about 0.002" to insure satisfactory operation. Again, if a gear is to be fitted on to a shaft permanently, it may be desirable to have a "force fit." That is, it may be desirable to force the gear on to the shaft which is to carry it with a hydraulic press. If such is the case, the shaft should be at least 0.0005" larger than the hole.

Many concerns have standardized "limit" requirements which are always followed for their drawings and construction. Other concerns do not specify limits. Since, however, it is a fact that quantity production work cannot be absolutely exact as to dimension and that the different shop men have different opinions, it is certainly better to specify different limits or give "tolerances" for dimensions of parts that fit together. This is particularly true of important parts.

For example, for a running fit the shaft diameter should be a certain amount smaller than the hole diameter. Thus the shaft diameter dimension may read $\frac{1.2475''}{1.2485''}$. This means that the diameter of the shaft when measured with micrometer calipers must lie between these limits. Again for a "force fit" the shaft should be larger than the hole. Hence, for a force lift the limits for the diameter of the shaft might be $\frac{1.2505''}{1.2510''}$. It is assumed that the hole is to be reamed standard size—exactly 1-¼".

Another method of writing limits is to specify the permissible variation. On this basis the limits for $\frac{1.2475}{1.2485}$ might be written 1.2480" ± .0005", or 1.2480" $\begin{matrix}+.0005'' \\ —.0005''\end{matrix}$. If it is understood that the permissible variation was 0.0005", then 1.248" ∓ might be a sufficient specification. Sometimes it might be desirable that the dimension of a finished piece be greater rather than less than the dimension specified on the drawing. Such a preference might be expressed by 1-¼+ or vice versa 1-¼—.

It is always desirable that the limits be specified in the drafting room rather than to leave these things to the man in the shop. If limits are not specified on the drawing the shop man must, before he can proceed, have a knowledge of how the parts assemble. To acquire this knowledge may involve an expenditure of time which could, partially at any rate, have been saved if the limits were originally specified in the drawing room. Furthermore, the draftsman has for consultation his handbooks, references and standard specifications. He is in a much better position to determine the desirable tolerances than is the shop man The Brown and Sharpe Manufacturing Company of Providence, R.I., has developed a system of limits for various purposes which, in practice, work out very satisfactorily and which may be found in various handbooks. It is true that before limits can be specified intelligently the draftsman must have a good working knowledge of shop operations and of the accuracy of operation of which the various machine tools are capable. He must also understand something of the characteristics of the man in the plant where the piece is to be machined and of the shop equipment therein.

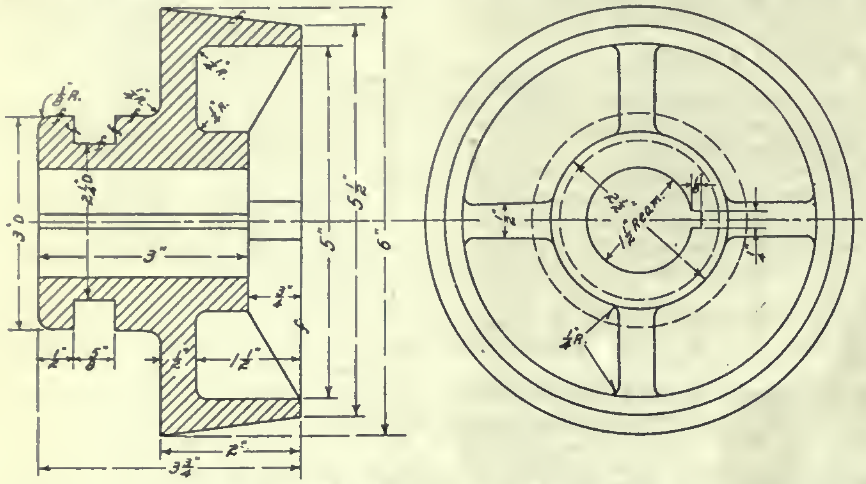

FIG. 26—CORRECT METHOD OF DIMENSIONING.

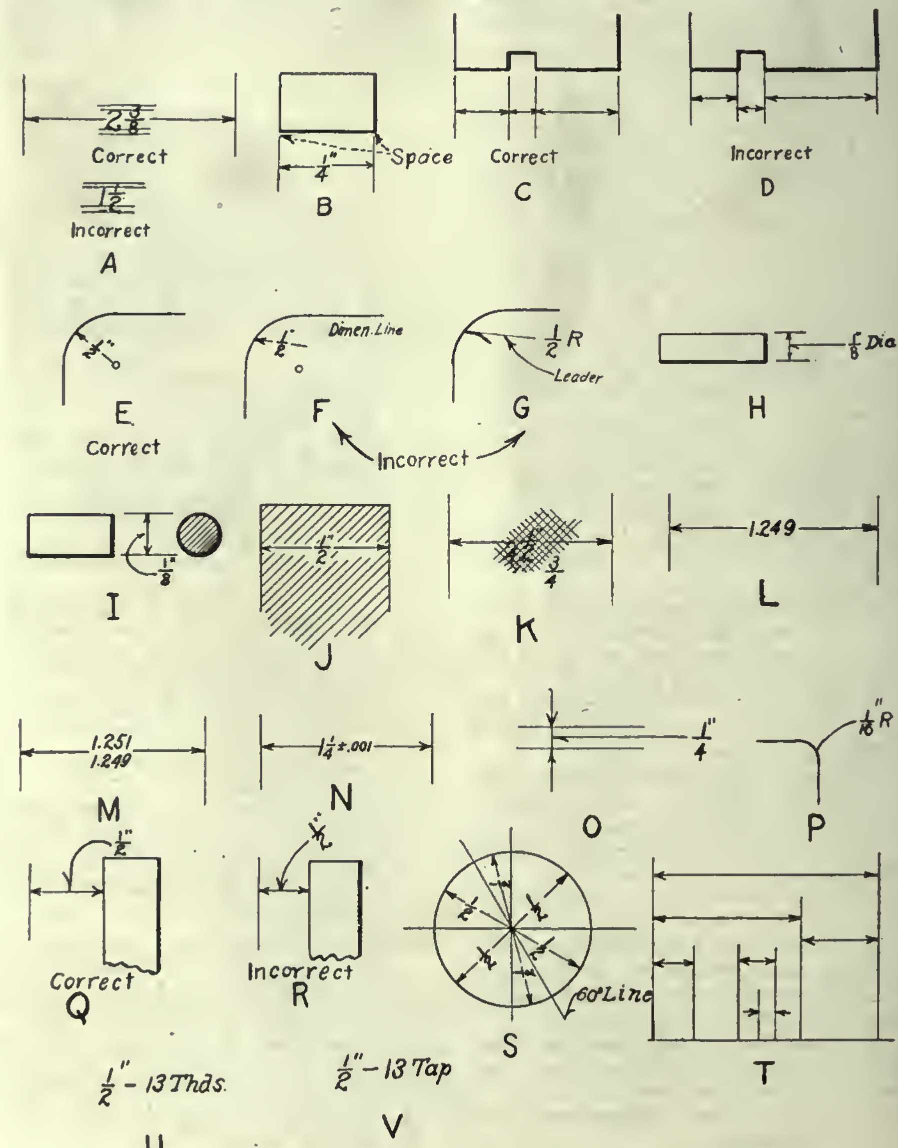

FIG. 27—FUNDAMENTALS OF DRAWING DIMENSIONING.

Vancouver Firms Pool Engine and Boiler Orders

One Order For Twelve Boilers and Twenty-four Engines Amounting to Well Over Half Million—Big Chance For Developing Carrying Trade Between Canada and Eastern Countries

BUSINESS amounting to between a half and three-quarters of a million dollars was placed with Eastern Canada concerns for contractors working on French merchant marine orders at the Pacific Coast. J. A. McCulloch, of Vancouver, acting for three firms at the coast, has been in Ontario for the past few days in connection with this work. His trip East had to do with a new form of buying that has been found satisfactory, viz., the pooling of orders and the appointing of one purchasing agent to place them all.

Mr. McCulloch has been closely connected with the munitions and shipbuilding business for some time in the West. His first experience was in the munitions business at Winnipeg, he having gone to the coast two years ago, and since then has followed the business of ship construction very closely from an engineering standpoint.

A Busy Place Now

"Shipbuilding has made the Pacific Coast a busy place," remarked Mr. McCulloch to this paper. "It looks right now as though the work in hand would guarantee that we would be well engaged for a year or eighteen months yet if nothing more turns up." Mr. McCulloch represented on his buying trip the Northern Construction Co., of Vancouver, the New Westminster Engineering and Construction Co., and the Pacific Construction Co. of Coquitlam. These companies have French orders now, 12 vessels in all. They are 1,500 ton French cargo boats, 205 feet long, 40 ft. beam, twin vertical, surface condensing engines of 275 indicated horse power. Mr. McCulloch's special business was the placing of the orders for the 12 boilers and the 24 engines needed for this work.

Can Buy Better

"We thought before, and we know now for sure that we can do better buying in this way than by each of the concerns sending a man down here to look for shop capacity to turn out the boilers and engines that will be required. If a man came into the East now with an order for a boiler and a couple of engines he would get a very scant hearing and delivery would be absolutely a matter of convenience to the shop handling the business. When a person can go to the makers of boilers and engines and say, 'Here is an order for twelve boilers and 24 engines,' we find that we can in this way secure the undivided attention of the shop and deliveries are better. This allows us to proceed at once with the construction of the vessels, and rush them along to the stage where they will be ready for the fittings to be placed in them. We know that a shipment will be coming along every month or so and this will fit in very nicely with our plans at the coast. Building ships is like making munitions. You don't want stuff piled up. You want to get a nice even flow of the necessary material to your yards just the same as keeping shells going through the various operations in a machine shop.

Who Gets the Work?

The contracts were placed by Mr. McCulloch as follows:

The Allis-Chalmers got 10 engines, of the type mentioned above, while Goldie-McCulloch of Galt will furnish 14 of the same type, 275 indicated horse power.

The first order for boilers was placed with the International Engineering Works of Amherst, N.S., the remainder having not been settled when Mr. McCulloch was preparing to leave, but this contract he expected to place before going west. In all the business was between a half and three-quarters of a million. Delivery will be made as far as possible to coincide with the progress of construction at the coast. The contractors with the French government rely on the fact that the work is for that government's war efforts to secure priority ratings that will enable them to get the material for the mechanical equipment needed.

A Great Work

"We have at the coast now six wooden and two steel yards, and there must be in the neighborhood of four thousand men working in these plants. It is estimated that a million a month is put into circulation through the operation of the shipbuilding plants. In the building of wooden vessels we are well situated at the coast in regard to timber. We can get practically everything that we need with the exception of some of the lignumvitae and other materials used for fitting."

In regard to the building of engines at the coast Mr. McCulloch considered that on the smaller types they could compete with the East, but on the larger ones it would be difficult. In fact this work has not been undertaken. The high freight rates worked against them to some extent. "But there is one thing of which I am tolerable certain," remarked Mr. McCulloch, "and that is that the Pacific coast could have had an engine building industry had they gone at it right at the start when there was plenty of work offering to give the industry the necessary work to keep going. The building of boilers could also have been established there as a good industry now. There was some uncertainty about the contracts at the start, when they did not appear to be of such a nature as to warrant much of an outlay. But the work that has been secured there lately both for wood and steel makes it certain that the boiler and engine proposition could have been established.

Looking to the Future

"What of the future? Will the shipbuilding industry be permanent in British Columbia?" asked CANADIAN MACHINERY.

"That all depends," remarked the westerner, "on whether they decide to go in and take advantage of the situation as it exists at the present time, and as it will undoubtedly exist for some time after the conclusion of the war. There is a great Pacific coast trade that is looking for some person to develop it. Some of the men at the coast claim it is the biggest opportunity that has ever opened, but it is going to take money and courage to develop it. The carrying trade from the Pacific coast of Canada to Japan and China is large and it is going to be larger. There are loads for bottoms both ways. If the Canadians don't get in and handle this trade it is going to be attended to by the people of Japan and China. That is the common belief of many of the men at the coast who pay a very great deal of attention to such matters, and there is very good reason for what they say. So far there has not been any movement made to meet this situation, but it should be handled by private interest. It is hardly a matter for direct Government action.

The Labor Situation

"How about the labor situation?"

"About the same as the East is," was Mr. McCulloch's opinion. "There have been too many strikes there on the coast. I regard the finding of Senator Robertson as a very fair and just one, although some of the labor men do not seem to see it that way. We have had no trouble in securing men for the work. Some of the men are beginning to see that high rate of pay generally brings everything along with it. It generally works out that way. Where wages run high the prices of commodities will not be far distant in the advance."

Prices for Material

In regard to prices for staple articles that go into the construction of steel ships, it is apparent that there is an advance of some size over prices here or at mills. In the matter of ship plate, it is sold from warehouse at the coast at 12 cents per pound. The Government at the present time recognize the price of 7½ cents at mills, while for points around here warehouses sell it at 10 cents per pound. Prices for all articles needed in brass trade are around the 40c mark. Mr. McCulloch believes that it is possible to establish a steel industry at the coast, and states that capacity could be secured the year around. "It is a fact, though," admitted Mr. McCulloch, "that Fernie coke has not secured the coast market, not because it is not good enough, but because the men who want it cannot depend on deliveries. There are fine ridges of iron ore near the coast. It will take capital and work to do it, but it is not impossible."

Mr. McCulloch is an Ontario boy, being born at Cornwall. He received his university course in Toronto, and has been working as a mechanical engineer in the West for some years, spending some time in Winnipeg with the Manitoba Bridge, after which he went to the coast.

A WORKING HYGROMETER

HYGROMETERS are used in factories for ascertaining the amount of water vapor in the air by means of a moving part in two forms—one employing a wet and a dry bulb thermometer, in which a fine thread of mercury is forced along a glass-tube by reason of the expansion of a small amount of mercury in a bulb. The other type owes its movement to the alteration of length of one or more hairs under the influence of a change in the moisture in the surrounding air. The movement of the hair actuates a small pointer moving along an index, and in the case of the thermometer the mercury moves parallel to the index. In each case the force represented by the movement is exceedingly small and the instruments as used in textile factories serve as a guide for the adjustment by hand of the humidifiers that furnish the additional atmospheric moisture that is required for the treatment of cotton in dry weather.

It has for many years been known that cotton is most easily spun or woven when it contains about 8½ per cent. of moisture; with less it is liable to be brittle and to have an increased loss in waste. The amount of moisture the fibre contains depends on the state of the air surrounding it, and as the dampness of the air is constantly changing, the cotton when exposed is constantly varying in weight. Along with this change of weight is a variation in thickness of each fibre, and this variation, when the fibre is spun or woven, results in a change of length in the fabric, although the loose fibre does not alter in length, nor does any vegetable fibre appear to do so.

As soon as moistening or humidifying appliances began to be used and the variation of atmosphere dampness from hour to hour during the working day was observed the need of an automatic regulator became evident, for no manual adjustment of water supply to the spraying apparatus could keep pace with the natural changes in the air. As a makeshift, the factory windows were closed and humidity was obtained at the cost of ventilation. The gain was, however, only a partial one, for excessive humidity produced lassitude among the operatives, resulting in bad work and irregular attendance.

Many inventions have been tried to obtain automatic adjustment of the moistening apparatus which used water at a pressure of about 100 pounds per square inch, but the resistance of the valves and stuffing boxes offered serious difficulties when attempts were made to control them by a movement due to the influence of moisture on organic fibrous material. A rope may be made to lift a hundredweight suspended on it by soaking it with moisture, but the operation would take so much time as to be of no use as a humidity regulator, and if it depended for moisture on the air it might take hours to show results. Promptitude is an essential in this case, for by carefully made experiments it has been found that loose cotton fibre is influenced in less than one minute by a change of moisture in the air around it.

The many failures of regulators controlling high pressure water supplies suggested a new departure, dealing with low pressure water which was atomized mechanically for air moistening. This invention was the subject of a recent patent obtained by Mr. John Wallace, of Bombay. The experimental regulator was a band of closely woven light canvas, 70 feet long, suspended by the edge beneath a roof and exposed to the influence of atmospheric change. The canvas was free of size and one was fixed, while the other was kept in tension by weight equal to four pounds per foot in width. The free end of the canvas was connected with a recording cylinder, on which a line was drawn that showed the movement of the canvas during every hour of the twenty-four. During a period of two years that the canvas remained in tension it showed no sign of fatigue, and it proved that a piece of canvas seventy feet long and three feet wide would indicate every change of atmospheric moisture in the air by a movement of 9-16 inch for each per cent. of moisture absorbed by the cotton while kept in tension by a weight of 12 pounds. The prompt sensitiveness of the canvas was due to its very large surface. Twelve pounds weight raised 9-16 of an inch thus represents the result of the absorption of 1 per cent. of its weight in moisture by the canvas band, and a test of the resistance to movement of a balance valve passing water full bore through a 1-inch pipe at one foot of pressure was 40 grammes, or about 1½ ounces.

This experiment points to the possibility of controlling automatically the supply of moisture in the air of a cotton mill, the regulator being of cotton. The canvas band has a certain length due to a content of 8½ per cent. of moisture within its fibres, and any increase or diminution of this moisture alters the length. Having a very large surface, absorption and evaporation take place very quickly, and with each change the movement acting on a balanced valve may control the water supply flowing to the vaporizers.

This device is applicable to public buildings, palaces and hospitals where electric current or other motive power is available.

CORK-LINED SHIPS

By D. Street

The efforts of all shipbuilders at the present day are directed towards making ships unsinkable by submarine action, and there are many and various means being considered as to how this can be done. However, all the deliberations have resulted in the conclusion being reached that more can be accomplished by increasing the reserve buoyancy of ships than by looking for means to divert the tremendous force of the torpedo aimed at the side of a ship. One of the methods of making ships unsinkable through the increase of their reserve buoyancy is that suggested by an Italian, whose method consists in lining all the available superficial parts of the ship's interior with a light substance such as cork. For instance, a steamer, a two-deck cargo boat, about 395 feet long and the usual lines, with a displacement of about 11,500 tons fully loaded, carries about 8,000 tons deadweight, and has about 423,000 cub. ft. of space available for cargo and bunkers under the main deck.

In order to render this vessel unsinkable it would be necessary to line the vessel internally with about 211,000 cub. ft. of cork composition having a specific weight of about 441 pounds to each 35 cub. ft. The cost of lining such a ship acording to this method would be about $200,000, whilst the capacity of such a ship would be decreased by 1,200 tons deadweight. The immediate objection to this scheme is that it is no easy matter at present to find cork in sufficient quantities to line ships. Now practicability and expediency are about the last things which enter the heads of those who propose means to safeguard ships against sinking after they have been struck by the deadly weapon known as the torpedo, against which nearly all schemes of protection adopted in the case of warships—which are not handicapped in the matter of internal subdivision through the necessity of reserving large compartments free from obstruction for the tonnage of cargo—have proved illusory, as is well demonstrated by the few instances on record of ships remaining for any length of time afloat after being struck in a vital spot by a well-aimed torpedo.

Still less commendable is a scheme put forward for increasing the buoyancy of ships by placing small watertight boxes in large numbers within the hull of a vessel and of distributing them in such a way as to interfere very little with the cargo capacity. The principle of the method proposed is that the aggregate floating capacity of the boxes will be sufficient to support the vessel and cargo after the hull is torn by a torpedo.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

RECTIFYING ROUGH BORED 155-MM. SHELLS

By M. H. Potter

INASMUCH as the most difficult operation in shell machining is the boring, considerable trouble and delay has of course been experienced in this particular operation. Moreover the government requirements upon this point are very rigid and exacting. Many shells have been temporarily turned down by the government inspectors owing to rough or scored bores. How this difficulty was overcome is fully described in this article.

The head illustrated in Fig. 1 can be used as shown in Fig. 2. The machine proper together with the shell carriage is illustrated by Fig. 5 and is described later on in this article.

The type of head shown in Fig. 1 was the outcome of considerable experimenting and produced first class results and shells rejected by the government inspecors were easily and readily rectified to their entire satisfaction.

The special shaped carborundum blocks A (see Fig. 1) are clamped in the jaws B as shown by the bolt C. The jaws B pivot at D. Naturally when the head is rotating centrifugal force throws the blocks A against the bore of the shell. This head was run at about 1,500 revolutions per minute.

The illustration, Fig. 3, although a different type of the head, is operated on the same principle. This head was designed to overcome the trouble and delays in production due to rough boring in the forward end of bore, after the nosing in operation. Owing to the rather small aperture a number of various designs were made up and tested, but the one herewith described was the only one which produced satisfactory results. Fig. 4 shows this head in the shell. The tubing A (Fig. 3) should be as large as permissible, the smaller tube B has an outside diameter that is about 1-32 in. to 1-16 in. smaller than the inside diameter of the tube A; in other words, when A is

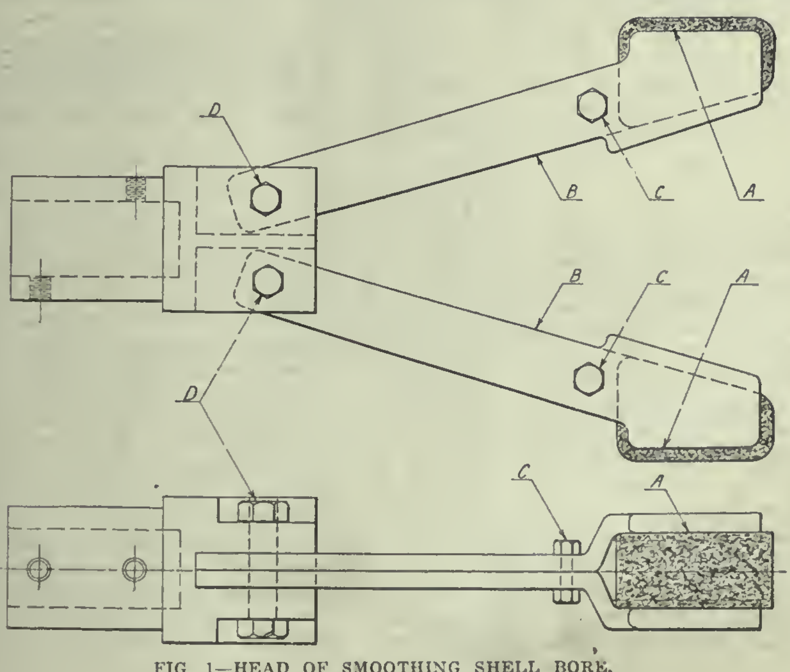

FIG. 1—HEAD OF SMOOTHING SHELL BORE.

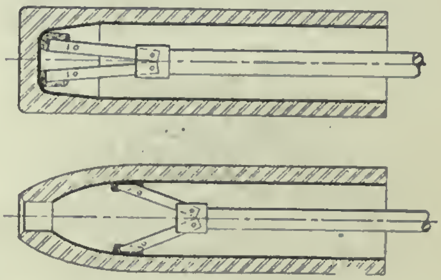

FIG. 2—OPERATION OF HEAD.

milled out half-ways B will just fit inside. The tube B is pivoted in the tube A at C. The carborundum block D is clamped by means of the bolt E. The flat arched spring G throws the jaw B outwards so that when the head is revolving it is subject to centrifugal force.

Fig. 5 shows the machine proper to which the heads previously described were used on. The shaft A (Fig. 5) is mounted on the two self-oiling rigid pillow blocks B and C. The tight and loose pulleys D and E are provided with an ordinary type of overhead belt shifter. The head stock casting G is bolted to the two structural steel "I" beams H, which form the bed. The legs I and K are also bolted to the "I" beams H. Owing to the excessive vibration rigid and heavy construction was maintained throughout. The carriage L, which supports the shell (shown by dotted lines) is mounted on flanged wheels and is reciprocated along the angle irons M. Two of the four shell carriage brackets N and O are hinged to permit rolling the shells in and out, the bench being in direct line with the shell carriage (at its back position, as shown in Fig. 5) to do away with unnecessary handling of the shells. The smaller sized shells (6 in. or under) will have to be clamped in the carriage to prevent them from rotating when being ground.

A NEW SHOCK RESISTING CONCRETE

By M. M.

Oil-mixed concrete we know; now comes an engineer and inventor (Mr. Lucien Linden) who patents a concrete composed mainly of Portland cement with particles of moss, turf, or wood (pulverized or pulped) and ores of metallic particles, with a binding liquid consisting of a soluble salt of alumina, lime and water. In addition, for concrete that will be much exposed to humidity (in foundations, for instance) or to violent shocks (in fortifications),

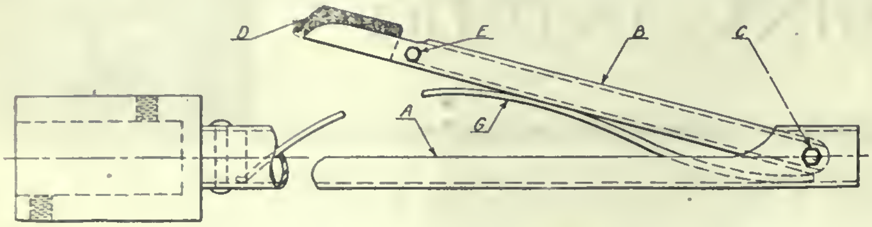

FIG. 3—ANOTHER TYPE OF HEAD.

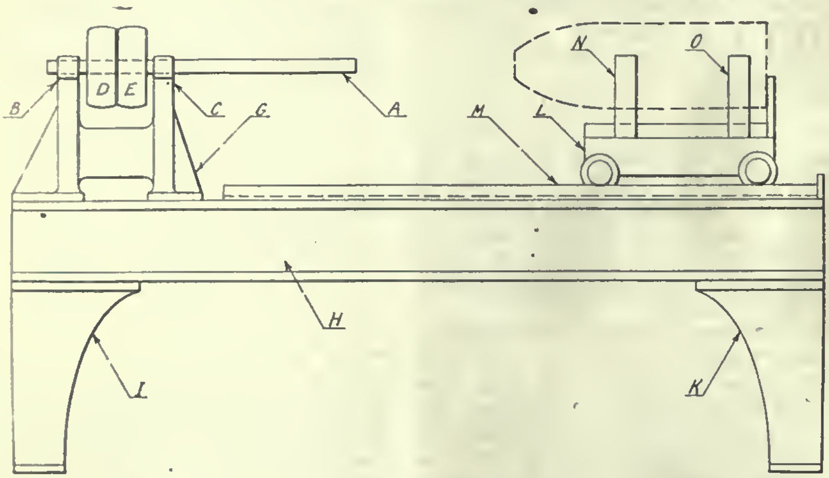

FIG. 5—SHELL CARRIAGE.

it may be advisable to add grease or oil, the fatty elements being introduced into the cement paste during the building operations.

The inventor advances the theory that the oil or grease will be progressively removed so soon as the paste becomes solid. They will spread all over, or progressively as oil stains in isolated spots, in the compound formed, so that greasy zones will be found encroaching upon hard and dry zones. The latter by acting in opposition, will impart to the thus formed bodies or structures a resiliency which will resist the disintegrating action of vibration or violent shocks. The fatty elements may be provided in the shape of pumice stone the size of peas, or of fragments of cork

FIG. 4—ACTION OF HEAD.

similar substances first dried and then soaked in fat, oil or grease.

The inventor states that the best method of producing such "grease zones" is to stretch through the soft cement paste straight layers of oil-soaked strings or cords. Generally a string provided in the centre of a body 3 in. thick, for instance, will suffice, many such strings, arranged net wise, to be used when forming concrete blocks. Similarly, strings that have not been oiled may also be used. The strings (greasy or otherwise) have also the effect of producing "isolated stretches" which arrest shocks, vibrations or other external or internal influnces which often cause ruptures. The strings or nets may be alone or arranged in conjunction with metal reinforcements.

The following, which the inventor gives by the way of exemplification, are said to yield excellent results:—

Formula No. 1.—(a) 100 parts of strong cement; (b) 5 parts of moss or turf well dried and finely cut and pulverized; (c) 20 parts of ore rich in iron in fine particles. These substances are formed into a paste by vigorous and prolonged mixing with a binding liquid, which liquid may consist of 5 kilograms of quicklime new from the kiln and broken up just before use, and of 3 kilograms of pulverized sulphate of alumina vigorously worked up in a cubic metre of clean water. This binding liquid plays an important part in the composition and amalgamation of the paste.

Formula No. 2.—(a) 100 parts strong cement; (b) 20 parts of soft wood (fine sawdust); (c) 10 parts of iron ore in particles, the whole being amalgamated with the same binding liquid as in formula No. 1. The above proportions (all by weight) and composition may vary according to the nature of the construction and use in view. Formula No. 1 is suitable for the construction of pipes, or ships; and Formula No. 2 can be used without any metallic truss rods or bars or wires, obtaining a material intended for doors, frames, packing cases, or rofing o rthe like.

Both of them may be adopted in a more diluted state, to make, when associated with gravels or fragments of bricks or stones, high class resilient concrete for foundations, walls or fortifications.

The reinforcement bars, rods, or wires, used with such compositions are preferably articulated, not fastened to one another, but indirectly connected together at the points of junction by means of insulating material capable of yielding.

Concrete made in accordance with formula No. 1 is so resistant and withstands expansions and contractions with such efficiency that it is also unnecessary to put hoops round the pipes even when the latter are liable to be subjected to high pressures. It is essential to work up vigorously and continuously the ingredients when they are mixed with the binding liquid.

The binding liquid is best prepared in a mechanical mixer, and the vegetable particles must be thrown into it and left for the former to act thereon, after which the cement is slowly introduced and then the metallic ore or ores pulverized or in small particles. The working up must be continued without interruption throughout the whole time during which it is formed and applied.

The successful use of the concrete depends on practice and experience. The material is especially adapted for high-grade construction such as ships. It can also be applied with advantage in the construction of pipes for water and gas, casks, boats, pontoons, reservoirs, railway sleepers, rail supports, floors, roofs, and walls.

MAY ESTABLISH LIGNITE PLANT

ESTABLISHMENT of a lignite briquetting plant, to be financed and operated by the Dominion, Manitoba and Saskatchewan governments, is recommended by the lignite committee of the Advisory Council for Scientific and Industrial Research. The committee report, which will be issued shortly, favors establishment of the plant in southern Saskatchewan at a locality where the lignites are of poor grade, with the idea that if it were successful at this point, it would be successful elsewhere in Saskatchewan and Alberta.

The report further states: "The art of producing carbonized briquettes has passed the laboratory stage and no further information can be got by laboratory methods. The producer must face the difficulties in commercial production, which are approximately of the same order as those within the smelting of certain ores. The road to success in the briquetting problem is strewn with the wrecks of amateur attempts to do this apparently simple thing, which accounts for the fact that private capital is so chary of such enterprises.

Labor Saving Washing Device Used on Shell Work

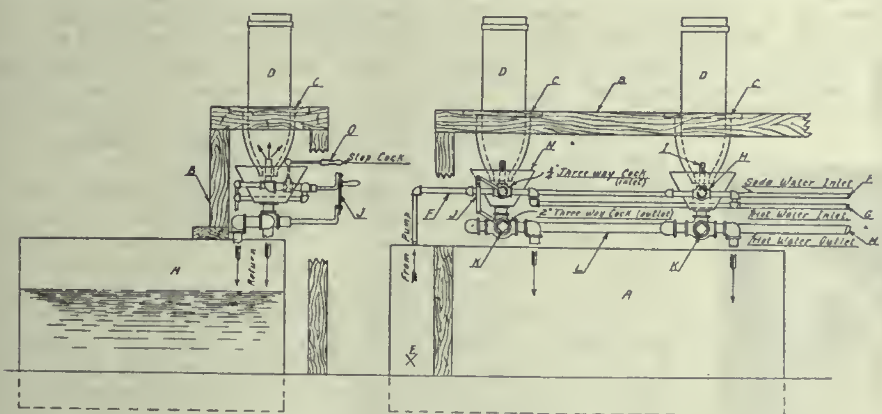
Absolutely Necessary to Have Interior of the Shell Perfectly Clean Before the Varnish is Applied—Various Methods Used and Good Results Not Hard to Obtain

By J. H. RODGERS, Assoc. Editor Canadian Machinery.

BEFORE the varnish can be applied to the interior walls of the shells it is necessary that every particle of foreign matter be removed to insure the adherence and uniformity of the coating. If this essential precaution is not taken the possibilities are that the varnish will not cling to the surface in a manner satisfactory to the inspectors, and invariably requiring the removal of the objectionable coating.

Various methods have been adopted for this purpose but the two more generally used are sand blasting and washing, or in some cases a combination of both. The device shown in the accompanying cut illustrates an arrangement for washing the six-inch shells, and one that has proved very efficient. As is usual by this method the shells are subjected to a spray wash of soda solution, followed by a rinsing with clear hot water. Little variation is made by different firms in the actual washing operation, but the method of application is seldom the same in any two plants.

Conservation of labor is one of the recognized factors in the operation of munition plants, so that the trend has been to eliminate all unnecessary handling of the work as it progresses through the shop. In many plants this washing operation is accomplished by placing the shell over two separate nozzles, one for the soda and the other for the clear water. With the device here shown these two washes are obtained with the one setting of the shell by a suitable arrangement of piping that permits almost instantaneous change from the soda to the clear water. The apparatus is so designed that washing of six shells can be proceeded with simultaneously, although this could be modified to suit any particular requirement.



DEVICE FOR SHELL WASHING.

Two adjoining tanks A are located in a convenient position with their bases placed below the floor level. The framework B is attached to the tanks and of ample height to support the shell above the nozzles. At intervals along the upper board are located bell-shaped castings C for holding the shell in an upright position. A small centrifugal pump E is placed on the floor at either end of the tank for forcing the liquid into the interior of the shell, the soda passing through the pipe F and the water through the pipe G. Three-way control valves H and K are operated in unison by the link J, this being connected to the valves by the levers shown. The soda return is by the pipe L and the hot water through the pipe M. Funnel pieces O are provided to avoid splash of the liquid.

THE SALVAGE OF SUNKEN MERCHANT SHIPS

By M. L.

There are now lying at the bottom of the sea with their valuable cargoes a great number of merchant ships, torpedoed by German submarines. Must they lie there forever or can they be refloated, as Germany is reported to have refloated and taken into Antwerp the North German Lloyd liner, "Gneisenau," which was sunk at the beginning of the war in the Scheldt? There appears to be very little doubt that many of the ships can be floated, and that a considerable quantity of cargo can be salved. The North Sea is sufficiently shallow for diving for cargoes, but there are a good many ships sunk in comparatively shallow water, which could be raised now if there were the men and the plant to do it.

There are few, if any salvage divers left. What salvage labor and machinery there was available in the British Isles has been requisitioned by the British Admiralty, and the same holds good in other countries as well. These men and plant are doing considerably more valuable work in helping the naval authorities than in looking after the commercial possibilities of salvage. In this, as in other matters, nothing can be done until after the end of the war. Then there will be possibilities for salvage work on a considerable scale, both in the North Sea and parts of the English Channel and other parts where the water is fairly shallow.

As to the question of deterioration, the fact is that neither ships nor cargoes, except perishable materials and foodstuffs. deteriorate very much in water. The chief damage that a ships suffers is when she is only half submerged and the engines are left to dry in the wind. Usually, when a vessel that has been wrecked is being refloated, a barrel of oil is poured on the surface of the water in order to leave a deposit over the machinery. Repairs are quickly effected, and sections torn by rock or torpedo present no great difficulties in the work of salvage, for they can be completely repaired. Valuable as are the ships themselves that now lie at the bottom of the sea, the cargoes of cotton, rubber, wool, cotton goods, machinery, and other materials are more valuable still.

The legal rights of salvage are those between the persons who are prepared to salve and the owners or underwriters of the vessels. A salvage company, for example, knowing that a vessel with a cargo of wool or cotton, has been sunk at a certain spot, will notify the underwriters that they are prepared to salve the cargo, and perhaps the ship, and they offer to do it. The question of the three-mile limit is not likely to arise. It depends on the terms of peace whether it will be possible for German companies to offer to salve the British ships they have sunk, and upon the feeling of British underwriters in the matter of whether they could consider them. There is no reason to suppose that Germany would be better equipped for the work than those of firms in other countries, but some of the German companies have more steamers but a much less amount of machinery. There are also good salvage plants in Holland, Sweden and Denmark, and doubtless they, too, will want a share of the valuable cargoes now strewn over "Davy Jones' locker."

Production costs at the plant for carbonized and briquetted fuel, covering operating costs and fixed charges, are estimated at not more than seven dollars per ton. In this estimate no finance allowance has been made for the recovery of by-products, which are stated to be large and valuable.

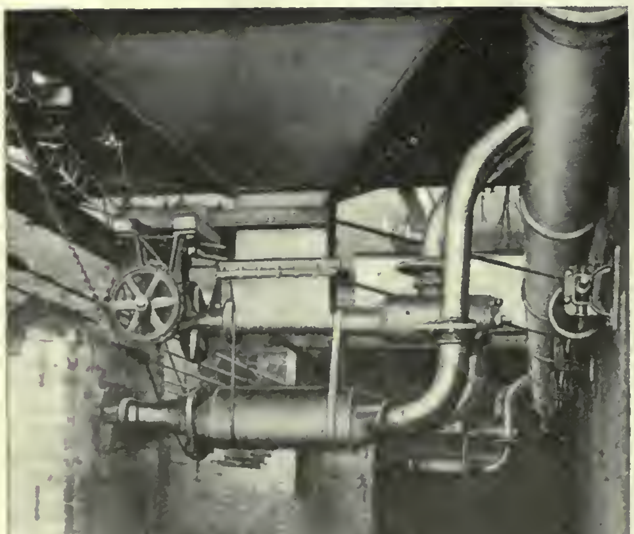
DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

POWDERED COAL CUTS COAL CONSUMPTION ON ANNEALING OVENS THIRTY PER PER CENT.

AT the present time when every effort is being made to spin out the energy of the coal pile and conserve our resources, the achievement of the American Radiator Company in very materially increasing its annealing oven capacity while at the same time effecting a startling economy in the consumption of fuel is of decided interest to industry in general.

The malleable iron plant of the American Radiator Company at Buffalo, N. Y., has long enjoyed the distinction of producing a superior grade of annealed castings under conditions of marked fuel economy. The annealing ovens have been equipped for burning powdered coal, the average consumption having been approximately one pound of coal to 3.5 pounds of castings annealed, the furnaces running about 96 hours per heat.



About the middle of November two annealing ovens, equipped with the Pruden carbureter, burning powdered coal under the carburization process, installed by the Powdered Coal Engineering & Equipment Company, Chicago, Ill., were fired and run for 96 hours. The first castings ran through the ovens before they had been dried out and the brick-work was extremely wet for the material had been lying in the open from three to four months and had become thoroughly saturated with water.

Mr. Harry E. Kies, manager of the malleable iron department, stated that upon completing the dumping of castings from the No. 4 oven he had never seen iron in quality and uniformity to equal it. Every piece had been perfectly annealed and these pieces were 25 per cent. tougher than anything that had ever been secured from the other furnaces equipped with the old burners. He stated that the saving in coal would be around 30 per cent., and that the next ovens would comethrough in 72 hours.

The burners ran all during the heat with no attention or adjustment, the operation was practically smokeless and observations made in the combustion chamber and flame passages showed that the ovens were heated to an absolutely uniform degree of temperature and that the flame circulated in every part of the ovens; on each side, around the bottoms and at the extreme back ends of the pots.

Examination of the ovens after the castings had been dumped showed that there had been no erosion or destruction of brick-work, indicating that with the new type of burners shut-downs for repair of brick-work would be reduced to a minimum, while the uniform degree of heating over the entire oven area, with consequent elimination of intensely hot zones indicated that pot losses (renewals) would be materially reduced.

Efficiency of coal consumption was increased from the previous record of one pound of coal to 3.5 pounds of castings to one pound of coal for 5.71 pounds of castings.

The coal used was a good grade of Kentucky bituminous, averaging about 12,500 B.T.U's.

		Carbon Briquettes.			
	Price of U.S. anthracite per ton f.o.b.*	Freight rate and switching from Bienfait	Estimated cost f.o.b. cars	Selling price profit of $1.00 per ton f.o.b. cars	Difference in favour of carbon briquettes
Winnipeg	$ 9.50 to $10.00	$1.90	$9.15	$10.15	$.... to $....
Portage la Prairie	10.00 to 10.50	1.80	9.05	10.05	.45
Carberry	10.55 to 11.15	1.60	8.85	9.85	.80 to 1.30
Brandon	10.60 to 10.85	1.50	8.75	9.75	.85 to 1.10
Virden	10.80 to 12.15	1.60	8.85	9.85	.95 to 2.30
Moosomin	11.00 to 12.25	1.80	9.05	10.05	.95 to 2.20
Wolseley	11.50 to 11.75	1.80	9.05	10.05	1.45 to 1.70
Regina	11.50 to 12.25	1.60	8.85	9.85	1.75 to 2.40
Moose Jaw	11.45 to 12.35	1.50	8.75	9.75	1.70 to 2.50

*Owing to the steady exhaustion of the anthracite resources of the United States, these prices will increase year by year.

VICTORIA, B.C.—Franklin Remington, president of the Foundation Company, wired Premier Oliver from New York as follows: "Have closed contract with the French Government for 20 wooden steamers. Will need our yard and also the Cameron-Genoa yard, as we have undertaken to lay down ten ways."

Optical Devices Aid Science and Industry

Combination of Optical Principles Enable Remarkably Interesting Results to be Achieved in Many Directions Impossible With the Telescope, Which Forms the Basis of all the Applications

IT seems hardly possible that the functions of a microscope, telescope and tele-photography could be united in one instrument, but the instrument herewith described accomplishes these things and in a maner which adds greatly to the usefulness of any standard microscope in the machine shop or other industrial plant.

Messrs. Davidson and Co., Great Portland St., London W., have recently produced a "micro-telescope" which is essentially an instrument consisting of a microscope of ordinary construction carrying a short focus telescope objective and tube below the stage. The ordinary terrestrial telescope consists of an object glass and an eyepiece which is nothing more nor less than a microscope of low power.

As well as supplying the instrument complete the makers manufacture two micro-telescope attachments, one for any distance from 3 feet to infinity and one of short focus for work from 12 to 24 inches. These attachments are made to fit the Abbe rim of any standard microscope and consist of a tube supporting a finely wrought object glass and a correctly graduated series of stops for the prevention of halation, the microscope becoming the eyepiece of the objective.

The focal range of the instrument complete is remarkably deep, the upstanding character of moss, lichen or fungus is clearly visible and in focus throughout. Dots on a card as close as 40 to the square inch are easily counted with this instrument at a distance of 3 feet. In the workshop, shafting, etc., or a part of a machine can be easily examined if light is thrown on it and with the use of a mirror to reflect light it is possible to inspect tubes of any length. Scales on thermometers can be easily read at a considerable distance and in ore smelting, glass, china, pottery and enamelling works and engineering shops, processes of firing and the action of furnaces used in heat treating, forging and other metallurgical operations can be closely observed at a comfortable distance.

One application of this attachment in the machine shop is the examination of the machining of a piece of metal that could not in the ordinary way be placed under the microscope.

With the use of a camera as shown in Fig. 3, it is possible to photograph whatever is seen by the use of the appliance and exposures as short as one-half second are possible. By means of the apparatus photographs of very distant objects can be secured.

FIG. 2—MICRO-TELESCOPE WITH SHORT FOCUS ATTACHMENT FOR OBSERVATIONS AT CLOSE RANGE, 12 IN. TO 3 FT.

In addition to the micro-telescope described the firm manufacture what is termed the super microscope for magnification up to 500 diameters at working distances of from 1½ to 1 inch. Ten times this magnification can be secured, but the working distance of the objective from the specimen is reduced in proportion. Up to 500 diameters the super-microscope can be employed without the mechanical stage for examination of objects too large for the stage.

The power of one microscope shown in Fig. 4 is in this instrument added to that of a secondary microscope the full combination being shown in Fig. 5. The primary shown to the left in Fig. 4 has a tube having stops and the micro objective to the right passes over the primary and carries a stage actuated by rack and pinion for vertical and lateral movements. Coarse adjustment of the secondary microscope forms fine adjustment for the super microscope, fine adjustment of the secondary then giving the extra fine adjustment.

An Abbe condenser can also be mounted and photographs are readily taken.

FIG. 1—MICRO-TELESCOPE FOR OBSERVATIONS 6 FT. TO INFINITY.

WATER POWER

By Mark Meredith

There can be no doubt that the nation would gain immensely by the cheap electricity which the promised sixteen pit-head power stations would make possible. But the setting up of these stations ought not to prevent us from giving every consideration such as, happily, is being given by the Ministry of Munitions to the developments of water power. We can never have too much power—the very lifeblood of industrial progress in this country; therefore we welcome every efficient addition to the resources of the nation in this direction of electric power production, whether that addition be coal produced gas-power or steam-power, or water-power.

There have been found in Egypt engravings of water wheels used by the ancient Egyptians on the Nile for grinding corn. The existence of such a machine is mentioned in the year 85 B.C., and Strabo records that Mithridates, King of Pontus, had a water mill. There were mills in Europe at the period of the Roman Justinian Code. The practice was often to moor barges in rivers, whose current in sweeping by slowly turned wheels on horizontal shafts projecting from the sides. This type of mill is to be found even at the present day in South Europe. Water power was used extensively in England over 1,000 years ago, the wheel being horizontal, and mounted on a vertical spindle carrying the mill stone.

The overshot wheel is the oldest and most extensively used. The water is led to the top of the wheel, in a direction almost tangential to the periphery through a chute called a "head race." The buckets become filled, and are carried down by the weight of the water. Actually, as the buckets tilt in descending, a considerable part of the water is lost en route. Thus the work which could be got from the water in falling from the head race to the exhaust, or "tail race," cannot be utilised. The wheel has to be nearly as high as the total fall of water, which should not fall more than 2 feet from the head race to the first bucket. It has also to be made just to clear the tail race water, which would otherwise retard its motion in flowing away. The diameter of wheel is thus only a few feet less than the height through which the water falls. Wheels of 80 feet diameter have been constructed. The loss due to water leaving the buckets may be minimized by careful design of their shape. With a well designed wheel as much as 85 per cent of the work available in the water can be utilised. An important point is that the machine is more efficient at low speeds, when less water falls out than at high speeds.

FIG. 5—SUPERR-MICROSCOPE COMPLETE FOR VISUAL OBSERVATIONS.

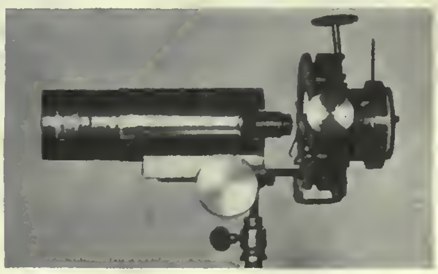


FIG. 4—THE PRIMARY MICROSCOPE WHICH ADDED TO THE SECONDARY OR REGULAR MICROSCOPE FORMS THE SUPER MICROSCOPE.

In the breast wheel the water enters at about the level of the axle, and is conveyed to the buckets by a circular arc of masonry or wood which fits closely to the edge of the wheel. Here the propulsion is partly by virtue of the weight of falling water, and partly due to the velocity in the tail race into which the buckets dip, the direction of motion being the same in this case. The flow from the head race is regulated by an adjustable sluice with passages so designed as to lead the water on to the wheel smoothly without shock. In some wheels, called "high breast" wheels the fall is almost as great as the diameter, and the efficiency is much the same as that of an overshot wheel. With a "low breast" wheel where the fall is less, the efficiency may be about 50 per cent. With the under shot wheel the water is confined against a lock gate and issues underneath through a sluice, impinging on radial vanes on the wheel. The wheel is moved solely by the impact of the water, whose dead weight plays no part. The wheels of Southern Europe are of this type and their efficiency is only 20 to 25 per cent.

The water turbine can be constructed for the largest powers and is immensely superior to all its rivals for efficiency. A gas engine of the best type will not yield more than 40 per cent of the energy of combustion of the fuel: a steam engine will yield less than 20 per cent of the energy in the steam supplied (neglecting foregoing losses in furnaces, boilers, pipes, etc); but a hydraulic turbine will give an overall efficiency of 75 per cent

A "House Organ" Sliced Up and Gazed Upon

And it is Shown How the Little Paper Puts the Millstone Around the Neck of a Whole Lot of Good Business Prospects—A Power For Good Kicked Into the Scrap Heap

Written by the Coroner Himself.

ARE house organs a paying investment? The writer will have the courage of his convictions and say, decidedly yes, providing they are run properly.

Because they are not run properly, it does not mean the idea is wrong. The idea is sound enough, it's execution that is usually faulty, hence the high mortality rate.

The large percentage of house organ failures is principally due to one particular fault, and that fault most always lies with the actual producer, or in other words the editor. He is prone to lose sight of the fact that there are, or should be, two distinct kinds of house organs, the internal and external, and because of this fact, the inevitable catastrophe happens, and mostly in this way.

A man or firm decides to publish a house organ with the idea of reaching their customers in a more direct and intimate manner. Fine. They spend plenty of money in securing the right kind of booklet. Fine again. They get the very best printer and engraver to combine their efforts so far as the appearance of the booklet is concerned. First rate. Then what do they do? They commence to assemble the reading matter. Watch out now, this is where the internal and external house organ are liable to get mixed. This is where the distortion of viewpoint comes in, and incidentally, where the label is affixed for the morgue.

Your editor maybe is first rate, in some respects, the only thing he lacks is experience in editing house organs. He may be a high class advertising man, full of pep, brilliant of inspiration, but he does not know house organs, or their funny little ways, therefore, he sets to work to entertain and interest his readers. And this is what he usually does, minus the diagnosis of his readers' needs.

He Heads For The Swamp

He will write a snappy and witty editorial, outlining the policy of his house and explaining the purpose of the publication. Great! He will then proceed in terms couched in sarcasm and satire, to give his opinion, not even the opinion of his house, mind you, but his personal opinion on some predominating political subject that might at the moment be worrying the country. Utterly wrong. He's paving the way for some enemies anyway. Then he will sandwich in a couple of pages devoted to his product. Fine again, so long as he only uses two pages and does not try to bulldoze his prospect.

And then—oh yes, he has a few good (?) jokes on hand—he uses these. They are bright but questionable; they have a distinct double meaning, and do not by any means reflect the dignity of the house. But still, our editor is a live wire, full of pep, and in they go. Wrong again; he loses more friends. If people want this sort of thing, they can buy books that contain it served up even more deliciously.

Goes Absolutely To Seed

And then he proceeds to put his foot in it still further; he commences a long-winded story about Bill Jones who has been in the service of his house for a number of years. More than likely Bill is a friend of his and does not object to reading nice things about himself, particularly if the article is adorned with a half-tone cut and amply retouched. Bad judgment again. The customer does not want to be informed regarding Bill Jones, even if he is the superman he is painted. Bill never entered into the customer's life, and in all probability the customer does not want him to.

Neither is the customer interested in George Giles who has worked for the company for sixty years, and is the head of three generations. That's not original, neither is it news; there are thousands of this type and our editor has absolutely no monopoly. Bill Jones and George Giles distinctly belong to the internal house organ and it's doubtful even then, because the other employees of the house have known it for years and are sick of hearing about it, especially of Bill Jones the superman, for the reason that they see Bill from the other side of the fence in his morning wrapper and boudoir cap, and with his hair in curl papers as it were.

Draws Deep On Imagination

So having committed himself so far, our editor continues to his doom. He selects a "real" sales story written by a man who couldn't sell goods if he tried, who tells how he entered the presence of a prospective customer with his hat on and a cigar in his mouth at an angle of forty-five degrees and sold him to the extent of $25,000. He tells all this not from experience, but from imagination and for sake of argument from some back garret situated in New York City. He omits to say, however, that his own ability as a salesman would be on a par with the memory professor who forgot his umbrella when calling upon a client.

And so our editor jogs along. He continues to do these things until the dummy is ready to submit to his president or manager. And the manager, he takes it for granted that it's all right for the simple reason that the editor had previously told him it was "easy to run a house organ." So it is mailed to the customer.

And What Does The Dealer Do?

And the customer? It's a new publication, therefore he'll likely read it. He gets through the editorial and on the strength of it reads further along. He comes to the expression of opinion on politics—and frowns. Out of curiosity he proceeds to the jokes—and rips out the page because he has several lady stenographers around. The mention of products is sidetracked for future reference, taking care that there are no more jokes on the other side of the page; and then he comes to the history of the superman, Bill Jones. At this he sneers, actually sneers, mind you, and says under his breath: "What the devil has Bill Jones got to do with me?"

About here he will be getting impatient, therefore poor old Giles gets short shrift, in fact nearly gets thrown into the paper basket; would have been in fact, only that a heading on the next page saves the situation. "How to improve your sales staff" is what meets his eye. He reads, he still reads, because utter rot is sometimes fascinating and then, "Hell, can you beat that?" And into the waste paper basket goes the child of our editor's brain.

THE majority of power plants of to-day have adopted CO_2 recording or indicating instruments in some form or another. These with other means of checking plant performance go a long way in the conservation of fuel.

When Is a Gamble Not a Gamble?

LAW is a sort of a funny thing after all. A merchant in Brandon is in a peck of trouble. He had a window with grab-bags in it. Some of them had something worth while, while others had not. The person who was willing to pay 25 cents took the chance of getting little or much. He might emerge from the scramble with a diamond that would sparkle like a new barn lantern, or again he might draw a prize that would look cheap in a bag of popcorn. At any rate the police got after the man and he's now up to explain his conduct on the charge of gambling.

At almost any large fair, exhibition or travelling circus there are a number of things go on that would make this practice look as flat as a well-made buckwheat pancake. There are straight games of chance run at all these affairs. Money is taken where only one in ten persons has a chance of winning. They toss balls and throw rings and try to beat sharpers at their own games. In fact, the stuff that is allowed to get by would make the wee sinner from Brandon look like a miserable amateur when it comes to real gambling.

But did you ever hear of many convictions against the circus people, or against the sideshow ilk that operate the large fairs or circuses? No, you did not. Occasionally there is a bit of a protest against the practice, but when it is made it is a lame duck and gets nowhere at all. The authorities reserve their powers of domination until they round up a few poor harmless Chinamen who are having a game of fan-tan and amusing themselves in this way. They are not out to bamboozle the public, but the authorities become wonderfully interested in the protection of the few Chinese who may lose their week's laundry cheques in this way.

The interpretation that is placed upon the meaning of "gambling" by the law interpreters is a gloriously vague and peculiar thing.

Larger Place Needed For Machinery

IT is quite evident that the Machinery Hall at the Toronto National Exhibition is quite out of keeping with the importance that the machine tool business and other lines of engineering product are taking on in the Dominion. There is small encouragement for the men who are in the business to go ahead and make a display truly representative of the industries in the building at their disposal.

There would have been a splendid chance this year to demonstrate at the fair the manner in which war work is carried on. True in some cases a few rough turning operations were in the course of actual work, but they gave no idea of the magnitude of the industry that has meant more to Canada in a commercial way than anything that has happened in her history.

There were great displays of material and processes that by the War Board would be ranked as non-essential in these times. There should be a determination on the part of the management to have the exhibits truly representative of the real things that are happening right at the time.

Of course, there are dealers, and many of them, who do not see any return for the expense of exhibiting at the Toronto fair. They claim that they can get better results in straight advertising, and that if they do put in a display in operation it is simply clogged with spectators who would never have any more occasion to buy a lathe than a barber would a bread mixer. The present facilities and the location of the building tends to encourage the manufacturers in this belief.

The Merchant Marine Should Be Recognized

THE week from September 1 to 7 is to be set aside in the Dominion as Sailors' Week, with the special purpose of raising money for the support of the dependents of those who have lost their lives while serving on the British Merchant Marine.

With the object there can be no quarrel. There is not even room for a good argument concerning the wonderful service performed on the trade routes by the gallant men of the Merchant Marine.

But with the system that allows the dependents of these men to be made the objects of a week's pity and hat-in-hand giving there is every fault to be found.

Why should there be no pensions for those left behind by these men? Is their service not as worthy of recognition as that of any other branch? Is the work they perform less honorable and less vital to the existence of the nation?

Not a bit of it. The great bulk of the hardships on the seas in this war have been endured by the men of the Merchant Marine. They have seen more of the submarine than any other branch of the service, and they have been instrumental in carrying men, supplies, ammunition—in fact everything that has enabled the Allied armies to carry on the war in the different fields.

In the face of the submarines, of the floating mine and the sunken mine, the men of the Merchant Marine went ahead, and with a courage that was wonderful and a tenacity of purpose that was traditional, turned an adverse balance in 1913 into a trade balance in 1917.

If the men of the Merchant Marine had shirked, this work would not have been done. The men in the front could not have been fed. The supplies and munitions could not have been sent across. The commercial supremacy of Britain could not have been maintained.

The service of the Merchant Marine is not a mean service. It is deserving of real and substantial recognition. It is not enough to depend upon "Sailors' Week," or tag days or voluntary giving. It should be recognized and rewarded on a straight and decent basis. There should be pensions and allowances for dependents of those who lost their lives in the service of the Merchant Marine, and it is high time the matter was put on the permanent basis that it deserves.

STEEL is quite an aristocrat. It has elbowed and fisted its way to the top of the price heap. Time was in days of old Pittsburgh production when as low as $1.05 per hundred was the market price. But prices in Canada are far removed from such lowly circumstances now. Price advances have came, but Steel has romped over the hurdle with ease in each case, and shows small tendency toward getting its heels going the other way. The man who pays the maximum $10 per hundred for plate now must regard the chap who used to pass it out around the $1 mark as a poor prune when it comes to a matter of salesmanship.

GREAT VOLUME OF BUSINESS PLACED

Big Overflow of American Orders Will Keep Plants Busy In Dominion

Canadian makers of munitions in recent months have secured American orders to the amount of nearly one hundred million dollars, and the prospects for the orders being doubled and trebled in the near future are said to be most promising.

The United States campaign of expansion of war effort as has been pointed out, is on such an elaborate scale as to tax all of their own industries and cause a big overflow to Canada. There are consequently the greatest possibilities for Canadian manufacturers benefitting with orders to an extent much in excess of the past.

The discrepancy in prices paid for munitions in the United States and Canada in certain cases is explained by the fact that on the other side manufacturers new to the business have, on the initial orders, been allowed a rate having regard to their capital outlay as was the case at the inception of the shell business here. When the industry is fully established the situation is different, and no allowance is made for the primary outlays on plant.

The appeal of the Munitions Board for increased output has met with a splendid response by munition makers all over the country. The prescribed limit is being fully lived up to, and the prices allowed are regarded as wholly satisfactory.

Cabinet Studying Matter

After discussing the matter with Mr. Harris, a sub-committee of the Cabinet was appointed to confer with him and the War Trade Board and work out details of a plan which will combine effective aid in the war, and at the same time stimulate the trade and industry of the country. The ground will be gone over and the capacity of Canada to do its part will be fully investigated.

One effect of the proposed plan will be to reduce the adverse balance of trade by greatly increasing the volume of Canadian exports. It is presumed also that restrictions applied by the United States on the export of certain raw materials will be moved in order to facilitate Canadian manufacturers in turning out munition and equipment orders designed for the common purposes of the war.

Upwards of a hundred million dollars of American munition orders have already come to Canada. There is some complaint, now the subject of negotiation, that the prices paid by the Imperial Munitions Board for the British army is considerably below those which rule in the States for similar work, and also below what is paid by the States to certain Canadian manufacturers who have secured orders independently of the channel of the Munitions Board.

CAPE BRETON GIRL WAR WORKERS BUILDING BOATS

Fourteen Are Now So Employed by Dr. Graham Bell at Beinn Bhreagh, Baddeck

The first that Cape Breton has seen of the real work of women as regards war work in the actual and practical labor side of it is in shipbuilding. Many of the young women in the city have read of the activities of women in the United Kingdom, the United States and in Upper Canada as farmers and munition workers, but here in Cape Breton they are building boats and for Government purposes at that.

Down on the Bras d'Or Lakes, where Dr. Alexander Graham Bell has a summer home and where he has been conducting many experiments, is a new one in women labor. Prof. Bell has started a boatbuilding plant and he has as far as possible employed women to do some of the work. In charge of the plant is Walter Pinaud, and under his supervision about fourteen young women and a number of men for the harder parts of the work and for instruction purposes are at work on dories and lifeboats which will be used by the navy. Already about fourteen of these boats have been completed and they have been tested and found to be up to the standard in every respect.

Columbus Was a Sticker

OCTOBER 12, long years ago, Columbus heaved a sigh, and pulled his boat on Yankee shore and landed high and dry—and so he got his name in print, we've read it forty times, in histr'y's prosy narrative, or else in jingling rhymes.

Columbus was a sticker, by heck he surely was, to put a kink ten inches through in all their sailin' laws.

Folks used to hold that if they sailed at some mad, killing pace, their tub some day would disappear and drop off into space—that big black men and wunks and things and wizzled witches, too, would pulverize the captain and feast upon the crew.

But old Chris C., he didn't give a rip for all their lore, so he hired a boat one sunny day and started to explore.

You know the story, course you do, of how the crew kicked up, and said he had a flattened head, and was a wall-eyed pup. They planned to hand to Chris a deal that was both cruel and raw—they'd kick his shin bones with their boots and whack him on the jaw.

But he kept sailin' straight ahead, chuck full of hope and trust—to find some new untaken place, or in the effort bust.

And when the thing looked just all in a sailor climbed a mast, and opened up his speaking tubes with one almighty blast—he'd seen some land right straight ahead, they'd hit it with a bump, and then they 'llowed that Christopher was not one all-fired chump.

It's been the same thing ever since, the man who don't get blue, but sticks right to his diggin' just like a hunk of glue—he gets there with both feet on top, in city or on farm—but there ain't much prospect for the man who crawls beneath the barn.—ARK.

Demand for Steel Still Away Beyond Capacity

Rather Serious Situation Developing—War Industries Calling For Steel in Greater Quantities Than Ever—Canadian Plants Are Going to Get More United States Shell Business

BUSINESS is going to be brisk in Canadian circles for some time to come if present indications are anything to go by. Dealers in the Dominion are purchasing again in large quantities. The renewal and placing of new business in Canada for the American government means that the munitions business is good for some time to come.

The developments of certain lines in Canada can proceed only along circumscribed lines at present. The real seriousness of the situation is not generally apparent. The War Industries Board of Washington is calling for steel at a rate that is startling. Right now the call is for five million more tons for first half 1919 than the present capacity of the furnaces and mills can show. Where the extra material is coming from is a question that is a very serious one for all concerns that look to U. S. production centres for their supplies. It means that restrictions placed upon the Canadian market will be strictly adhered to, and there will be a tendency to make these tighter than in the past.

Pittsburg reports indicate that it is almost useless to go to the mills armed with priority certificates and licenses and preferences. In fact all such documents look alike now. It is generally found that all the mills have plenty of customers who have been armed with similar documents, and the preferences, etc., are simply placed on the books together with plenty of other preferences just as good.

British Columbia is placing large orders in the East this week. Just a few days ago a purchaser representing three shipbuilding concerns on French orders was in Ontario placing orders for 12 boilers and 24 engines. He claimed that in this way he could secure much better terms and delivery dates than by the three companies going into the market individually with smaller orders. His total buying represented about three-quarters of a million dollars.

The scrap metal situation is more serious in United States than in Canada. A larger amount of scrap than usual is finding its way into foundry mixture. Some of the dealers are inclined to hold that there is plenty of material in the consumers' yards, and that the talk of a shortage is being kept up to keep shipments from being allowed to United States points, there having been an embargo against this for some time past.

IT IS SMALL USE TO GET ARMED WITH PREFERENCES OR PRIORITIES

Special to CANADIAN MACHINERY.

Pittsburgh, Pa., Sept. 5.—The very brief statement that was given out in New York to the press relative to last week's meeting in New York to consider conditions as to steel supply evidently does not begin to cover the proceedings. The meeting was attended by representatives of the War Industries Board, the producers of pig iron and steel and some consumers of steel. Evidently the situation is so delicate that publicity as to precise measures to be taken is not considered desirable.

The situation is that there is a wide gap between the steel requirements and the prospective output. The War Industries Board some two or three months ago estimated the steel requirements for the current half year at 20,000,000 net tons. Now it places the amount at not under 23,000,000 tons, and intimates that 25,000,000 tons might be more accurate. Furthermore it has furnished the steel makers such details of the items composing the total as to leave no doubt in the minds of the steel makers that the amount ought to be provided if at all possible.

On the other hand production will do moderately well if it exceeds 18,000,000 tons, and quite well if it reaches 19,000,000 or 20,000,000 tons. About 6,000,000 was produced in the past two hot months, and while a moderate increase is to be expected this month, and quite a heavy production in October, there are the usual dangers of curtailed output in the winter.

Steel for Offensive

The increase in the War Industries Board's estimate of total steel requirements shows that there have been additions to the list. As to the general character of these additions there is no uncertainty. They represent distinctly steel to be used in offensive warfare, and thus the increase in the total estimate can be linked directly with the remarkable change that occurred in July in the character of the operations on the western front, whereby Marshal Foch assumed not merely the offensive but the initiative, an attitude which has been continued with increasing vigor. The alignment is reflected in a very large increase in the shell steel requirements and in the demand for large numbers of rolling field kitchens. For the latter there has been a rapid canvas of the possibilities of furnishing merchant bars for axles and framework, sheets for bodies and tin plate for tinware equipment, besides many minor items in finished steel. There have been increases in the war steel demand along other lines, details not being given yet.

New Shell Steel Producers

Two important wire departments are to be converted for the rolling of shell rounds, chiefly 82 mm., a large part of the tonnage to go to French shell factories. These are the Donora works of the American Steel & Wire Company and the wire department of the Jones & Laughlin Steel Company's works at Aliquippa, both near Pittsburgh. The small billet mills in these departments, hitherto used to roll billets for the rod mills, are to be replaced by equipment for rolling large rounds. The rumored cost of the changes is so large as to suggest that some changes may be contemplated in the steel making departments at these plants.

All the additional shell steel that is to be rolled at various plants, however, does not represent a net addition to the shell steel supply, for the reason that at one rail mill at least the production of shell steel has had to be decreased in order to provide the larger tonnage of rails required. There is the 200,000 tons recently allotted for shipment to the A.E.F., and there is heavier rolling of rails on old orders of domestic roads. So much tonnage is due the domestic roads on their old contracts that little if any new buying will be required by domestic roads for this year.

Less Steel for Some Finishing Departments

The shutting off of wire production at the two wire plants just mentioned will hardly be made up by increased wire production at other plants, hence a net decrease in the production of wire is in prospect. Other decreases will likely occur. The production of merchant bars, which has probably ranged between 60 and 70 per cent. of capacity, is likely to come down, even though question has been raised whether the previous production has been sufficient to maintain important industries more or less helpful in winning the war. It is almost certain that in the not distant future the supply of sheet bars will be further restricted, but whether this will fall upon tin plate mills or upon sheet mills, or upon both, remains to be seen.

Of Very Little Value

With the wider gap between steel requirements and steel supply, a mere place upon the preference list is of relatively little value. Substantially all the war activities have their place, in order, upon the preference list, also all the commercial activities that have been recognized as contributing to the success of the country's war work. The priorities in favor of direct war material, first specifically granted in each instance, but lately made the subject of "automatic priority" by the buyer certifying the purpose, are, however, so heavy that they leave little steel for such purposes on the preference list as do not also have priorities. As to class D steel, which is steel that might be left after priorities and preferences were taken care of, that is practically forgotten. Many mills concluded long ago, by the way, that there was a sort of "catch" in this class D stetel, in that if they should apply for the required permit to ship steel as class D the application would be interpreted as an acknowledgement that the tonnage was actually to spare, and the War Industries Board would call for the steel for a required purpose instead of granting the permit sought.

Production

Attention has lately been focused upon the fact that some blast furnaces are not making their normal output by reason of coke shortage, and the Fuel Administration is insisting that the Railroad Administration furnish absolutely full transportation facilities for the movement of coal to by-product ovens. Of late several furnaces in the Chicago district have been forced to bank, their attendant by-product coke ovens not being fully supplied with coal. The weekly reports of coke production would seem to suggest that there ought to be an ample supply of coke for blast furnaces, but there must be a loose end somewhere, either a distribution to some purposes not so essential as pig iron manufacture, or a deficiency in quality requiring the use of too much coke per ton of pig iron. The furnaces in blast ought to be good for a production of 42,000,000 to 43,000,000 tons of pig iron a year, instead of the 40,000,000 to 41,000,000 tons actually being turned out.

POINTS IN WEEK'S MARKETING NOTES

Field kitchens of the mobile variety for the use of the allied armies on the west give some indication of the way the trend of the war affects the making of steel.

—

Pittsburgh mills report that there is very little use having preferences and priorities, as the mills are clogged with orders all made up in this manner.

—

The Baldwin Locomotive Co. is out with a list looking for the purchase of 1,049 machine tools, probably the biggest single demand ever brought on the market.

—

The government demands in U. S. are so heavy for steel that no plans are being made to manufacture pleasure cars after January 1, 1919.

—

Scrap dealers in some cases hold the view that the talk of a shortage of scrap material in Canada is for the purpose of keeping up the embargoes against shipping material from this country across the border.

—

A purchasing agent from the coast representing three shipbuilding concerns, placed orders in the east this week for twelve boilers and twenty-four engines, the coast firms believing that they could buy to better advantage by pooling their business.

—

There is good reason to believe that shell contracts that expire about the end of September will be renewed, and that they will run well over the first half of 1919.

—

Dealers in machine tools in Canada believe that there will be many months yet of activity in the selling of machine tools for munitions work, as well as supplies.

—

The call for plate is greater than ever, and on this account the usual allotment of ingots for other lines is being curtailed to increase the rollings on plate.

—

The War Industries Board of United States places its first half 1919 requirements of steel at almost 5,000 tons past the present capacity of the plants.

—

Steel output is recovering from the hot weather curtailments, but it will only be a matter of a few months, the trade fears, until the troubles of cold weather and poor transportation become prevalent.

SEE GOOD BUSINESS FOR MACHINE TOOLS

Renewal of Contracts Will Mean Steady Demand for Equipment in This Country

TORONTO, Sept. 5.

BUSINESS has been brisk in the machinery trade for several years in Canada. It is brisk right now, and from indications that can hardly be questioned or doubted it looks as though it would continue brisk for some months to come. There has been a large volume of trade moving apart from the equipping of plants for war work. Orders come in for odd lots from all parts of the country, and in the aggregate they amount to a big item. In some cases war contractors are adding a few extra tools to their equipment to get the best results, while in some cases domestic business finds it necessary to add to their plants. The trouble is that business in Canada that calls for a supply of steel is up against a stone wall in the matter of supply. There are all sorts of large contracts that are waiting patiently to get a chance at the allotment of steel that is made to Canada by the War Industries Board at Ottawa. Were it possible to get all the steel and iron required at the moment there would be an industrial development and expansion that would be startling, to put the case mildly.

The Call is for Plate

The call for plate is loud and insistent. In fact there seems to be a growing belief that everything that comes from the open hearths will have to be flattened out into ship plate or boiler material. There seems to be no possibility of the capacity of the rollers catching up to the demands that are being made on the output.

Dealers in this district are having some trouble satisfying the trade that their orders are getting the consideration due them. Priorities and ratings may be secured, but that is no sure indication that delivery will follow, because plenty of other concerns have been armed with just such documents, and the later orders are simply placed on the books to wait their turn.

Pooling Their Orders

Vancouver firms having orders for the French government are pooling their business, and this week a purchasing agent from the coast was in the east representing three of the companies that will handle twelve carrying boats on French order. He placed orders for twelve boilers and twenty-four engines, the business going to the Allis-Chalmers and GoldieMcCulloch for engines, and to the International Engineering Co. for a good part of the boiler work. The purchaser claimed that he was satisfied that by the pooling of orders in this way he had done much better than had the three firms in question gone out into the market and placed their orders individually.

Scrap Piling Up

Dealers in second hand material claim

that there is accumulating a large amount of material in the yards in the Dominion, and they also say that in some cases the larger users have a good supply on hand and are to all intents and purposes out of the market for some weeks. Users in many quarters, on the other hand, claim that they cannot get supplies necessary, but in many cases it will be found that these places are not on war work. Some of the dealers are inclined to claim that users of scrap keep up the reports of shortage of material in order to keep up the embargo on shipments from Canada across the border.

As a matter of fact domestic trade is rather slow because munitions business has first call on the scrap yards the same as it has any place else. On this account there are grades of second-hand materials that are not being called for to any great extent.

Machine Tool Business

Dealers in Toronto have met a large number of out-of-town users of machine tools and equipment during the week. A large number of sales have been made, although in some cases promises of delivery have of necessity been very vague. The advantage of dealers having their work well laid out and planned before they promise deliveries has been amply demonstrated several times during the past year. There are cases right now where contractors have received good deliveries, almost on time, while for other parts of their plant the delivery schedule is simply shot to pieces. The result is that no progress is being made.

The munitions business is being well handled now, and CANADIAN MACHINERY understands that contracts with shops that have been obtaining good results are going to be renewed. This refers especially to the 75 m.m. work, some first contracts for which expire about the end of September. In fact it is believed that arrangements are well under way for the carrying on of orders well in 1919. This means more business for machine tool dealers, for supply houses, in fact for all the various branches that have been influenced in their volume of business by the carrying on of the munitions business in Canada. There is a brisk demand for makers of machine tools to get out goods for the Canadian market, the dealers here being confident of their ability to handle almost anything that they can arrange for.

The situation here in many lines, as pointed out before, rests largely on the ability of U.S. production. The authorities at Washington have no small matter on their hand. Their desire is to bring output to as near the 100 per cent. standard as possible, and at the same time they are confronted with the necessity of meeting the calls of the draft for men at the front. Between the two there must be a fine adjustment, and one that will call for keen foresight and fearlessness. At the present moment the supply of coal is a big problem, as several large furnaces have been banked lately because the output of coke was not sufficient to keep them all in operation. In such a case the authorities simply direct the available supply to be turned to the plants making the materials most urgently needed at the moment.

WANT TO USE MORE SCRAP TO SAVE PIG IRON, BUT CANNOT SECURE SUPPLY

THE scrap metal situation, in a broad sense, is a peculiar one just now. In some cases the authorities in United States are urging the foundry interests to use larger amounts of scrap in their mixtures, with the idea of making the supply of pig iron go farther. These shops claim now, and apparently with good reason, that they would do so if they could get the scrap they require. There is a shortage of scrap in United States, while in Canada fairly large stocks are on hand. Reports from U. S. points are as follows:

Chicago: Rolling mills grades are in fairly good demand, otherwise there is a keen and a decided shortage. Heavy melting steel is not coming out in the usual volume, and users stand ready to make large purchases. Those who refuse to pay commissions are having more trouble in securing supplies than those who remunerate the dealers.

Pittsburgh: Demand for all grades of scrap continues strong. There is scarcely a large consumer who would not take heavy tonnages could they be secured. Heavy melting is much demanded as well as low phos. scrap, but machine shop turnings are also inquired after. Stocks in the yards of the dealers are not as large as they were a year ago, and dealers see no chance in many cases of making replacements. The labor situation is also a factor as yard men are scarce.

Cleveland: In ability to get sorters for the yards in some cases here has caused dealers to turn down business as they claim they would be doing the trade a poor service by sending out material at random.

Cincinnati: From all reports that come to this centre there is a shortage of scrap material that is unprecedented. Dealers state that they have not enough material coming in to fill orders and are constantly forced to draw on their reserves, while these reserves are being depleted at a very rapid rate.

St. Louis: Dealers here charge that the usual sources of supply for old material have been dried up, and there is nothing where big tonnages used to originate. Stocks of consumers have been sadly depleted and they are willing to buy anything they can secure at reasonable prices. The labor situation is described as the worst since the war, and it is becoming worse instead of showing the expected improvement.

New York: Offering supplies here in scrap are at a rather low point, and it looks are though they would remain in that condition for some time. Labor is scarce and material moves slowly through the yards.

Philadelphia: The trade here has come across several cases where foundymen have been requested to use a larger proportion of scrap in their mixture to ease up on the iron situation. They can't do it because the scrap necessary for such a movement is not available.

PRODUCTION OF PIG IRON DOES NOT GROW FAST ENOUGH TO MEET NEED

THE production of pig iron seems to have reached a point past which it is hard to force it, according to reports from United States producing centres. There is a shortage of coke because there is not enough coal coming to the ovens. Steps are being taken to remedy this, but it is not an easy matter, as it comes largely to a question of man-power, and both the army and the industrial world are now calling for the men most fitted to do this class of work. Reports from some of the larger United States points show the following:

Chicago: The total sales made for 1919 delivery are not large. In fact they are small. There is no encouragement to tieing up for next year delivery.

New York: One maker of pig iron made inquiry of the War Board regarding the taking on of 1919 business, and was advised that such a course could not possibly be sanctioned. The result is that his output is to be left entirely to the allocation of the authorities at Washington. The belief is growing that some non-essential users of pig iron will be eliminated or severely curtailed, and that there will be enough iron only to take care of the shops that are working on government-sanctioned orders.

Buffalo: Shortage of coke is hampering a few of the producers in this district. It is a generally understood thing now that it is not much use approaching the mills for 1919 bookings, as they are quite content to let the bookings take place after the allotment has been made by the government authorities.

Cleveland: One of the large furnaces here that has been changed over to basic will be turned back to foundry iron for a short period to provide relief for some of the users who have been almost shut off from a supply for necessary work. The British Government has a large order for basic in this district and it will have to wait for a few days until relief is secured for the foundrymen.

St. Louis: Interests hereabouts have

had men in New York and Washington to canvass the situation, and they report that there is going to be no surplus of pig iron. The demands for domestic work are simply colossal, but there is not even a remote chance of any of these being considered for some time to come.

Philadelphia: The discussion of costs and the fixing of values for the fourth quarter are interesting the men in the trade here just now. It had been planned to bring in a large tonnage of low phosphorus iron from Spain. This would have relieved the situation, but the question of bottoms had not been fully reckoned with. It is impossible for the present to get shipment from Spain, and the plan has been for the time being abandoned.

Pittsburgh: Some of the pig iron makers here, discussing prices for the fourth quarter, claim that higher rates should be paid, owing to the increased costs from labor charges and transportation. They state that their earnings have been whittled down to a fine point. Although the weather has improved for furnace and rolling mill work, there has not been a decided gain in production figures owing to a shortage of coke. This is the first time in many months that production in this district has been interfered with on this account.

CUTTING OFF THE PLEASURE AUTOS

U. S. Government In Market for All the Steel There Is In Sight At Present

Special to CANADIAN MACHINERY.

New York, Sept. 4.—The Baldwin Locomotive Co. has come into the market for several million dollars worth of machinery to be installed in plant which it is building at Chicago, reference to which was made in this report about the middle of July. The list just issued calls for 1,049 tools, being the largest single inquiry ever placed before the machine tool industry in this country. Inquiries for cranes, also to be installed in this plant, are expected to be put out soon. Other manufacturers of railroad motive power are expected to come into the market in the near future. The Davenport Locomotive Co. has just purchased $30,000 worth of tools in the Chicago market.

Several railroads that put out inquiries some weeks ago have now made purchases of machine tools, including the Monon and the Rock Island; the St. Paul and Sante Fe are also in the market. The Elgin, Joliet & Eastern has closed bids on a large lot of shop equipment. The Pennsylvania, the Erie and the Central of New Jersey are about to place orders for cranes.

In the last few days, interest in the machinery trade has been centered in the placing of large Government orders for motors for airplanes and tractors; several of the companies that have received such contracts have been buying machine tools. These orders are of significance because they have immediately followed the unfavorable report of the Sub-committee of Military Affairs concerning the airplane program of the Government. The Willys-Overland Co., Toledo, has just received a contract for 5,000 Liberty airplane motors and for 3,000 tractor motors of 12 and 8 cylinders.

The Locomobile Co., of Bridgeport, which is making Liberty tank motors, has completed purchases of tools for the equipment of its new shop. This company has also taken over the motor contracts of the Trego Motor Corp. of New Haven. The Pierce-Arrow Motor Car Co., which is making Hispano-Suiza motors, has made additional purchases of tools to carry out its contract. The Union Switch & Signal Co., Pittsburg, to increase its output of Lerhone Airplane motors, is buying additional shop equipment. The H. H. Franklin Manufacturing Co., Syracuse, is purchasing additional machine tools to manufacture motor crank shafts for the Wright-Martin Aircraft Corp.

Using Automobile Shops.

Government contracts for airplane motors in large quantity and for motor parts to be used in repair work are expected almost immediately. The intention is to utilize as much of the capacity of the automobile shops as is possible. The heavy Government demand for steel will leave so little metal available for making passenger automobiles that no plans for making pleasure cars after Jan. 1st, 1919, are being made. The Velie Motor Vehicle Co., Moline, Ill., has received a Government order for tractors. The Ford Motor Co., Detroit, is to make a large number of "whippets" or small tanks for military service in France. Another Detroit automobile maker is already manufacturing large fighting tanks. The Willys-Overland Co. is manufacturing shells and gun carriages as well as motors for the Government.

Several Government departments have pooled their locomotive crane requirements for a year, the Crane Section of the War Industries Board having allocated orders for 600 cranes of such type for the War and Navy Depts., for the Director of Military Railways, for the Railroad Administration and for the Emergency Fleet Corp. The capacity of the plants manufacturing locomotive cranes, which amounts to 108 cranes a month, has been absorbed for six months. As a result of these large Government orders, delivery dates on other contracts for locomotive cranes have been postponed until next March.

Water-power engineering has suffered in the past from an unfortunate concatenation of circumstances which have led to its comparative neglect. Great Britain is the home of inventive genius and of mechanical skill, and consequently the trend of engineering development all over the world has been largely along the lines dictated by British conditions. There is no generator of energy which is more efficient than the water turbine properly designed; there is probably no more wasteful device than a steam boiler and engine. There is waste from start to finish; much of the heat of the coal passes away through the chimney, more is lost by conduction and radiation from the steam in boiler and pipes, and still more, in fact the greater part, is wastefully expelled with the exhaust from the engine. But the engineer found to hand a great store of coal, and natural water power is comparatively absent, so the generation of power from the combustion of coal or other fuels has received the greater part of his attention.

CAPTAIN JOSEPH O. GRAY

Capt. Joseph Osteers Gray has been appointed shipping master for the port of Montreal. Capt. Gray is well known in Montreal as the founder of a pioneer school of navigation and seamanship.

CAPTAIN J. MURRAY WATTS.

J. Murray Watts, naval architect and engineer, of Philadelphia, has been commissioned captain in the 57h Engineers (Inland Waterways).

Uses of Compressed Air in the Modern Shop

Least Possible Amount of Clearance, Efficient Cooling of the Air Cylinders and Rapid Action of the Valves Are Points That Come Largely Into the Question of Efficiency in Operation

By P. C. FRANK

FIG. 2—ENGLISH PNEUMATIC TOOLS IN SERVICE CHIPPING RAIROAD TIRES AT THE BOLTON IRON AND STEEL PLANT.

IN the modern shop the pneumatic tool is almost universally used and the air compressor whether operated by the electric motor, by gasoline or other internal combustion engines or by the steam engine or steam turbine, is now considered practically indispensable. The accompanying illustrations Figs. 1 and 2 show the use of pneumatic hammers at work on English castings and pneumatic tools in service chipping railway tires at the Bolton Iron and Steel Plant, at Bolton, England, the Boyer hammers noted in use having been supplied by the Consolidated Pneumatic Tool Co., Ltd., of Westminster, London, England.

The drawings Fig. 3, 4, 5 and 6 show the air compressors of the single simple stage types, and series of intercooling types, belt, rope, motor or steam driven with electric pneumatic control as developed by Isaac Storey & Sons, Ltd., at Manchester, England.

These engineers point out that the history of modern air compressors has followed in line with that of the steam engine, the old compressors and steam engines being made with a very long stroke and running at a moderate speed, modern ones with a shorter stroke and higher speed. The development in the direction of a much higher speed of revolution has been very much assisted, in the case of the air compressor, by the numerous electric installations which have been put in, a compressor running at a high speed being eminently suitable for driving by electric motor. The vital constructional points, according to these English engineers, for a compressor which shall give the highest efficiency include the least possible amount of clearance, efficient cooling of the air cylinders, efficient intercooling, and rapid action of the valves.

As to cooling and intercooling it is pointed out that, during compression, heat is generated, and that some method must be employed to cool the heated air, and thus ensure that the air is maintained at its greatest possible density during compression. The only practicable method of withdrawing the heat, and that generally adopted, is to water-cool the cylinder and its ends, and to employ intercoolers, through which the air is directed in its passage from one cylinder to the other.

It is claimed by these English engineers that the system of cooling in the Scott compressor presents great advantages, and is more efficient than that of the many types of jacket-cooled compressors These latter types rely solely on water jackets or chambers of small capacity cast on the cylinder or cover, and, owing to the various ribs, inlet and outlet ports,

FIG. 1—PNEUMATIC HAMMERS AT WORK IN AN ENGLISH SHOP.

joints and branches, the water space is broken up into a number of pockets containing only a small volume of water in each, thus greatly reducing the effective cooling surface and efficiency.

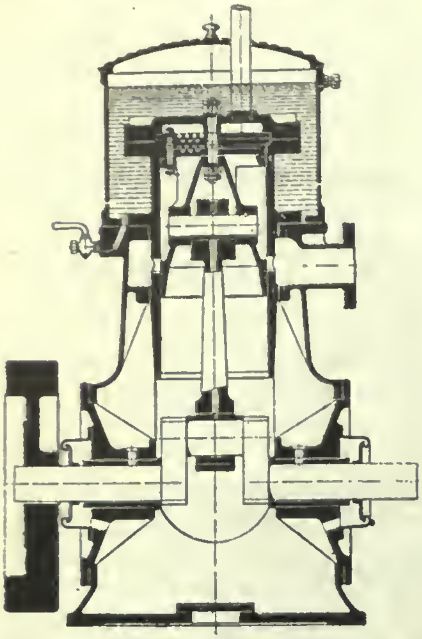

FIG. 3—ENGLISH SINGLE CRANK AIR COMPRESSOR DEVELOPED AT MANCHESTER AT THE PLANT OF ISAAC STOREY & SONS, LTD.

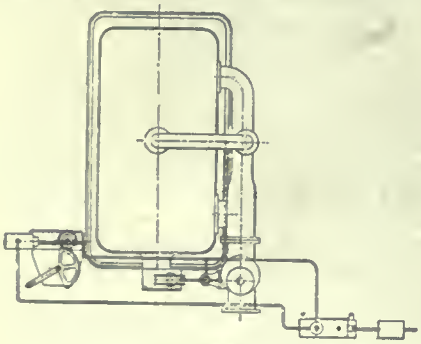
In the English compressor, noted in the drawings, a far greater cooling efficiency is obtained by the arrangement of totally immersed air cylinders, which, owing to the fact that they have no large piston valve or other chambers cast on, are perfectly cylindrical, and lend themse



PNEUMATIC ELECTRIC CONTROL

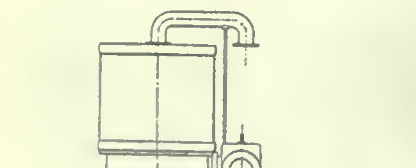


FIG. 5 ENGLISH COMPRESSOR CONTROLLING DEVICE.

peculiarly to this system of cooling. The cylinders and intercoolers are completely surrounded by a steel tank through which a large volume of water is circulated, the connections for this purpose being made in the frame and not in the tank, so that the tank can be lifted off without disturbing any of them, and the whole of the joints and surfaces of the cylinders and intercoolers are then exposed to view.

It will be seen that as usual the air after being compressed in the low pressure cylinders, passes through intercoolers to the high pressure cylinder, These intercoolers consist of a set of brass tubes expanded into tube plates in the ordinary way. The air is however passed through the tubes, instead of being passed outside, as usual, while the intercoolers are immersed in the cooling tank. The result is that the air is divided up into a number of small streams, so that this form of intercooling is much more efficient than any other method. In ad-

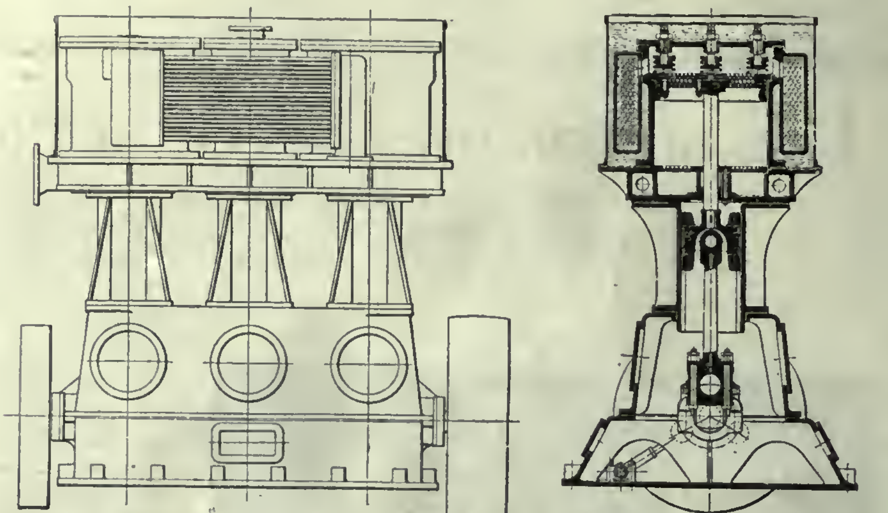

FIG. 4—SCOTT INTERCOOLER COMPRESSOR DEVELOPED AT STOREY WORKS, MANCHESTER.

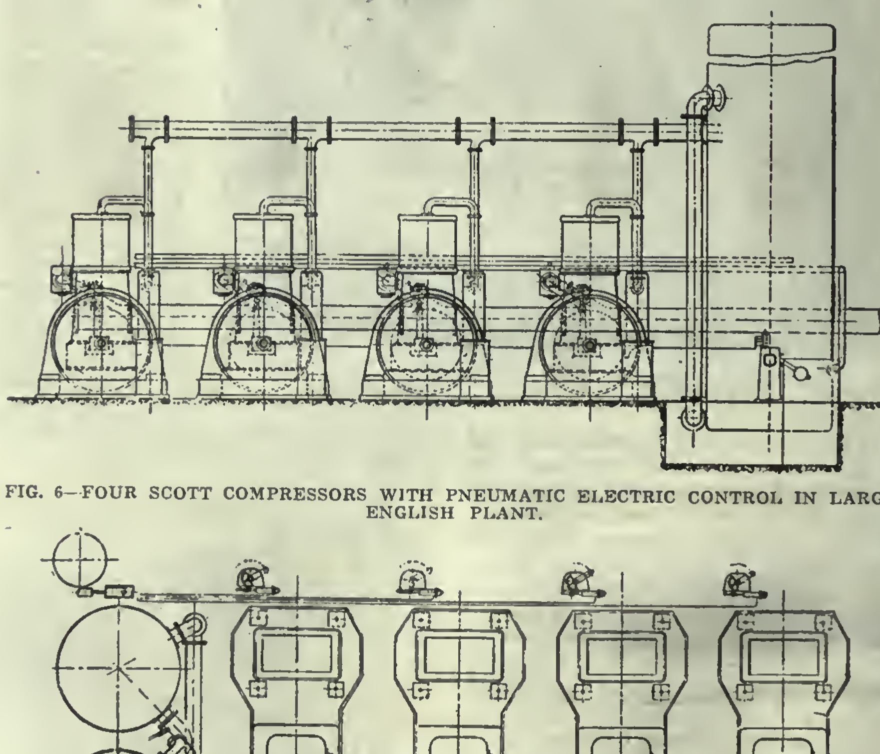

FIG. 6—FOUR SCOTT COMPRESSORS WITH PNEUMATIC ELECTRIC CONTROL IN LARGE ENGLISH PLANT.

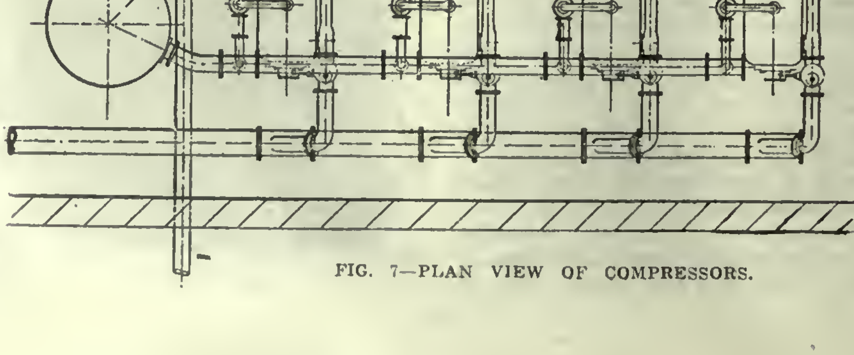

FIG. 7—PLAN VIEW OF COMPRESSORS.

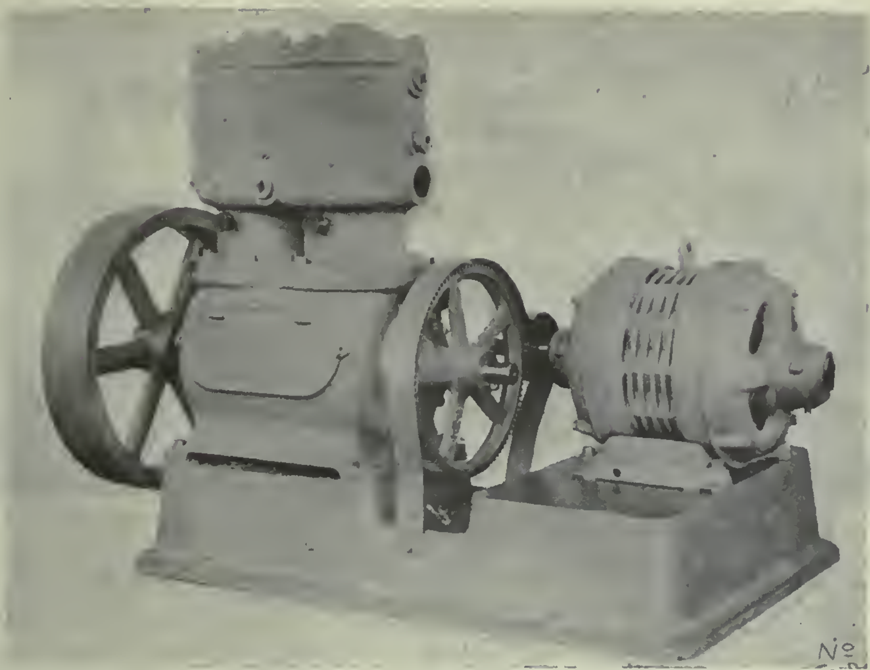

FIG. 8—AN AMERICAN MOTOR DRIVEN AIR COMPRESSOR

dition, the formation of air pockets in the intercoolers, which has given so much trouble with many compressors, is entirely obviated. A further advantage is that practically any water can be used for cooling purposes, as the arrangement is such that any deposit on the surface can be easily removed, while the presence of the large and freely moving body of water in the tank keeps down the water temperature, in consequenceof which the amount of deposit is not nearly so great. the automatic devices for unloading and governing the supply of air are provided in accordance with the particular installation.

The drawing Fig. 3 shows the simple single stage Scott compressor which consists of a frame and bedplate similar to an ordinary high speed engine), provided with bearings for one or two cranks according to the particular size of compressor. The top of the frame has the inlet air passage cast in it and the compressor cylinders, provided with inlet ports around the circumference, are fixed in bored holes in the frame, and each is fitted with a trunk piston worked by a connecting rod from the crankshaft, the annular part of this trunk piston being in constant communication with the inlet holes.

It is held that the form of the valve plates and the very small lift of the valves required to give full area make it possible for the clearance spaces to be reduced to an extent impossible with any other design. There are no valve pockets or ports, and the cylinder clearance can be so small that the piston and valve plates practically touch. The only parts requiring lubrication are the crankshoft bearings, the connecting rods, and the trunk piston and cylinder walls, and all these are lubricated by splash lubrication in the enclosed crank chamber.

The lower end of the truck is fitted with rings to prevent the lubricant being drawn in with the air. By means of oil throwers, fitted at each end of the crankshaft, any oil which has worked through the bearings to the ends of the shaft is flung by centrifugal force on to the inner walls of the oil catchers which are fitted on the end covers. The covers are provided with an oil drain at the lower side of the oil catcher, and the oil is thereby free to drain back into the crank chamber. By these means, ample lubrication is ensured, with satisfactory continuous running and extreme cleanliness.

The totally immersed system of cooling is effected by extending the casing sufficiently high to allow the water to cover completely the topmost part of the cylinder or cylinders. The top of the body casing is machined, and a removable water jacket is provided for this purpose. By this means the whole of the air cylinder and cover is completely immersed in a large body of cold water, thus ensuring that the air is kept as cool and consequently as dense as possible during compression. By draining off the water and removing the jacket the cylinder joints can be easily examined, as all pipe connections are made in the body casing and not in the jacket.

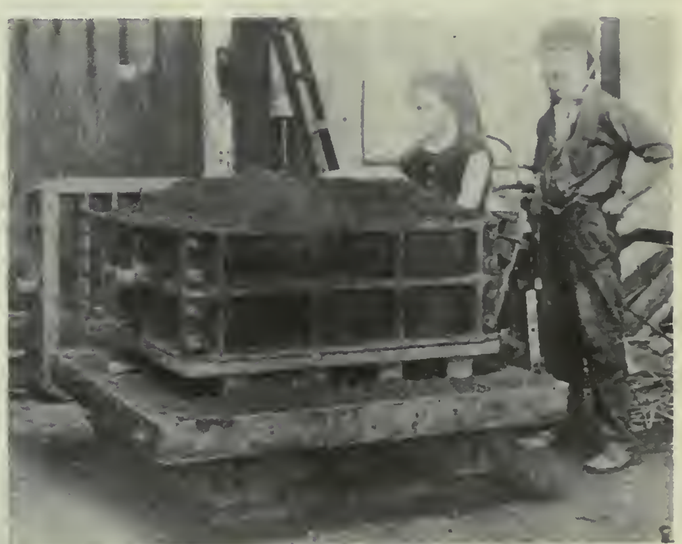

FIG. 9—AMERICAN PNEUMATIC MOULDING MACHINE DEVELOPED AT ZENLENOPLE, PA.

It is claimed by these English engineers that in compressors running at a high speed, the valves, generally, are the weak point and in this compressor the introduction of ball valves has given the simplest and most durable type of valve possible and they do not hammer their seats away. It will be readily understood that owing to the fact that each valve weighs but a fraction of an ounce, and has only a small lift, the impact on closing is extremely small, the wear being almost

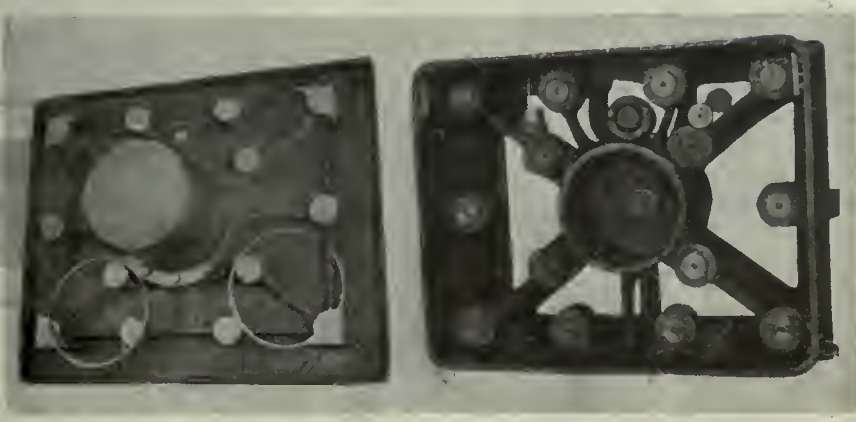

FIG. 11—THE HERMAN PNEUMATIC MOULDING MACHINES DEVELOPED AT ZENLENOPLE, PA.

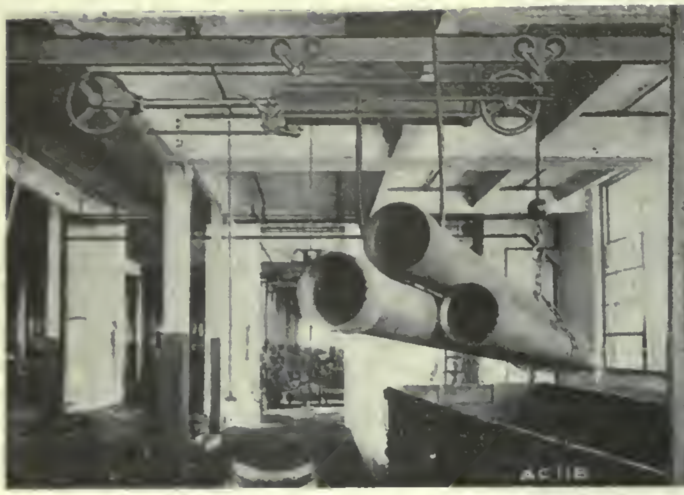

FIG. 13—CURTIS PNEUMATIC CRANE IN PIPE PLANT.

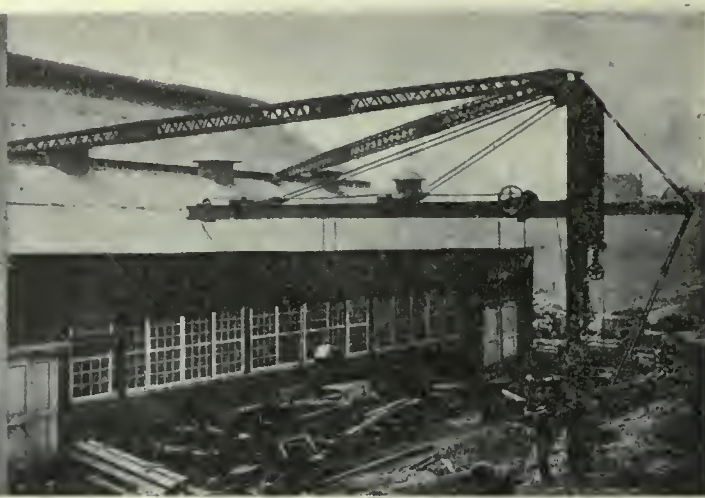

FIG. 14—PNEUMATIC SHOP YARD HOIST IN SERVICE.

negligible. This is proved by the fact that many of these valves have worked continuously for considerable periods without showing any appreciable signs of wear. A further advantage is the lightness of the valves enabling high speeds to be attained with silent running.

The valves, which are a special feature design, are in the form of hardened ground steel balls of small diameter, each working on a recessed drilled seating made from hard steel plates. The bottom plate is drilled with a series of holes of two diameters, the top portion slightly larger than the ball, and the lower portion smaller in diameter than the ball. This forms a pocket, in which the ball works, and a seat for it to rest on. The upper plate is drilled to the same templet as the lower one, and is then fixed so that the holes in it come half way over the holes in the lower one, the solid bars between the holes in the upper plate coming directly over the centre of the balls in the lower plate, and so forming a stop for the lift of the valves. Both the delivery and suction valves and plates are made exactly alike and can be easily examined or changed when necessary.

It will be seen that the upper side of the piston is fitted with a set of plates and ball valves, the air to the cylinders being admitted to these valves on the suction or down stroke. The position and rapid opening of the valves is automatically ensured by the inertia of the balls at the commencement of the downward or suction stroke. It will be observed that at the end of the compression stroke, when the piston commences its suction or down stroke, the rapid movement of the piston causes the inertia of the balls to pull them quickly off their seats, and thus opens the valves at the precise moment desired. At the lower end of the stroke, the momentum of the balls instantly closes the valves immediately in the commencement of the compression or up stroke, which is exactly what is required.

It will thus be seen that a very large area through the valve plate is obtained with an extremely small lift, which is, in fact only about 1-16". This gives a high efficiency, and results in extremely durable valves and seats, without the use of either springs or other complicated devices. Owing to the large outlet ports and valve chambers in nearly all piston or disc valve types of compressors the clearance spaces are extremely large with the result that the efficiency is considerably reduced.

In this English compressor there are no valve ports or chambers and owing to the unique design of the ball valves, large clearance spaces are entirely obviated, and the cylinder clearance can be so small that the piston and valve plates practically touch, thus ensuring the highest possible efficiency. It is almost impossible to wear out the ball valves or seats, as the balls work round and keep themselves absolutely tight for any length of time, and further there is no liability to fracture or any other damage, so common in the valves of many other types of compressors. There are no

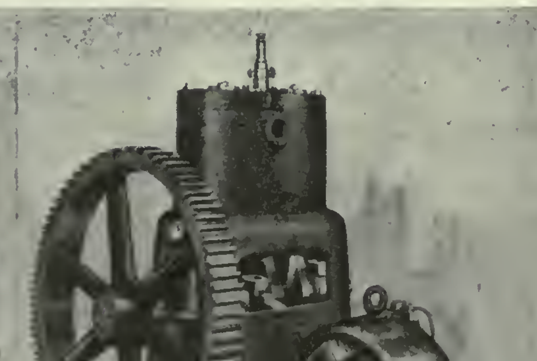

FIG. 18—ELECTRIC AIR COMPRESSOR WITH DRIVE GEAR.

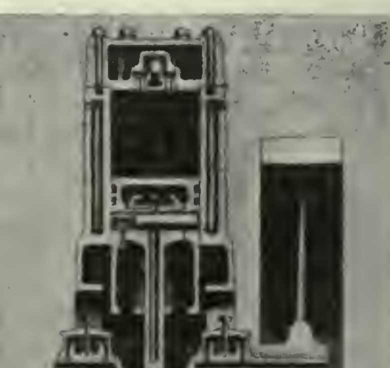

FIG. 15—CURTIS SINGLE CYLINDER AIR COMPRESSOR.

springs used in connection with the ball valves. Such springs, necessary in nearly all compressors, are a serious cause of trouble through their constant failure from fatigue, which often results in considerable delay, expense and annoyance before renewals are completed.

The drawing Fig. 4 shows one of these English intercooling compressors, designed for large capacity owing to its

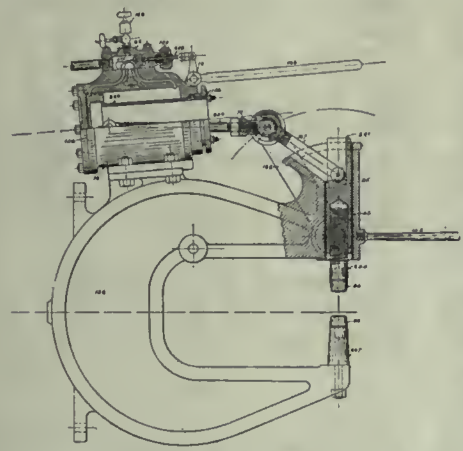

FIG. 19—A PORTABLE PNEUMATIC RIVETER FOR STRUCTURAL, BRIDGE AND RAIROAD WORK AND BOILER AND TANK CONSTRUCTION.

extreme regularity of turning, due to the correct equalizing of the pressure relations in the three cylinders. Especially is this so in the case of electrically driven machines, where the advantages due to this equal torque are very great, when the questions of the life of the motor and steady, continuous running over long periods are considered. It will be seen that the three cylinders are mounted on distance pieces and body casing similar to those of a high speed engine. Two of these cylinders act as low pressure and one as high pressure, the arrangement being that by these means an equal division of power is obtained between the three cranks, and a much cooler delivery of air in consequence of the proportioning of the compressions between the high and low pressure cylinders.

The delivery valve plate, which is designed to secure a minimum clearance, is held down by strong springs from the outer cover. These springs act as a safeguard in case the connecting rod wears loose and the piston strikes the delivery valve plate, which, it will be seen, is recessed into the upper part of the barrel and forms the top end of the cylinder. With this safeguard it is thus possible to work the compressors with such a minute clearance as 1-32 of an inch.

The drawing Fig. 5 shows the controlling device on the compressor which consists of a centrifugal governor combined with throttle valve on the inlet and an air pressure cylinder, and is arranged so that the compressor continues unloaded until it is within 10 per cent. of its full speed. When the pressure of air exceeds a fixed amount, the air cylinder acts on the throttle valve and again unloads the compressor. The combination of these two arrangements results in a control which enables a compressor to be unloaded, and therefore to be started without injury to the motor, and which also cuts off the supply of air when the pressure arrives at a desired point.

The control for starting and stopping the motor consists of a main air pressure cylinder with a number of units in the plant, which are run in series, and a control cylinder on each switch. These control cylinders are of the differential type, the small end being in constant communication with the air pressure main. The larger end communicates with the reservoir, and is filled with liquid from the reservoir to the cylinder, being controlled by adjustable valves. Air is admitted to the reservoir from the corresponding holes in the main air pressure cylinder previously mentioned. The regulating valves between the reservoir and the cylinder are so arranged that the speed of movement of the switch in the two directions can be varied independently and at will, and in the ordinary way this control is set so that the switch is thrown out of operation in 5 seconds and put into operation in 40 seconds, but this can be varied to any reasonable extent at will. This system of control contains no complicated parts, and is easily understood and kept in order by an ordinary mechanic, and it is perfectly certain in its action.

The drawing Fig. 6 shows an installation of four of these large English compressors working together in a large shipyard in the North. The compressors come into action one after another, as the pressure falls, due to the requirements of the service, and they go out of action in the same manner.

In American foundries, shops and quarries, the pneumatic tool and the air compressor are almost universally employed. The accompanying illustrations, Figs. 9, 10, 11 show the compressed air jarring machine developed at Zelienople, Pa., by the Herman Pneumatic Machine Co. The Herman jarring molding machine depends on the use of the compressed air for the perfect jarring of any cope and drag successfully in the foundry. The base and the table plate is of one size, and at different points in the base pockets are machined out, in which are placed rubber discs and on top of them steel discs. The table plate is of cast steel construction and blocks are cast at points, so when the table plate drops, strike on the different jarring blocks in the base. Guides are cast in the table plate and in the corners of the base guides plates are placed. These relieve the wear on the cylinder and it is impossible to get a load off centre so that the cylinder or the plunger is in no way affected. It is claimed that in this works and in these machines the pneumatic jarring principle was first used for molding machines.

In the many American machine shops and foundries and factories, pneumatic elevators and hoists are utilized to advantage also in the yards for handling the raw material and finished product as indicated in photographs, Figs. 12, 13 and 14. In the accompanying illustrations, Figs. 15, 16, 17 and 18 may be noted the details of construction of the Curtis air compressors and of the electrically operated air compressors with belt and gear drive developed at St. Louis, Mo., by the Curtis Pneumatic Machinery Co.

These electric air compressors are full self-oiling with controlled splash and regulatable sight feed cylinder lubrication. It is claimed that they have 80% more cooling surface than any double-acting compressor of the same capacity and the heads and valves being water-cooled as well as the cylinder walls increase the volumetric efficiency. The machines are self-contained, considerably heavier than other compressors of similar capacity, assuring freedom from vibration, admitting of light foundations and withstanding the excessive strains due to speed and high pressure. The automatic unloader makes this compressor especially economical and desirable for intermittent service. The controlled splash oiling system with its regulatable sight feed of the oil fed to the cylinder, its consequent saving in oil and attention is another feature found only in the Curtis compressor. The discharge for the water circulation is taken from the heads or in other words at the highest point of circulation, so that there is never any possibility of the hot water becoming pocketed or trapped in the heads, and there is no possibility of water circulating without passing through the heads.

How Hun Plotters Worked in Canada Early in War

Dastardly Attempts to Destroy Property and Prevent Canadians From Reaching the Front—How United States Kept in Touch With the Plotters and Spoiled Their Plans at Every Turn

By EARL E. SPERRY and WILLIS WEST for U. S. Committee on Public Information

THE second chief purpose of the German Ambassador and his lieutenants in America was to prevent Canada from giving military aid to England. That this enterprise was carried on at the command of the German General Staff is indicated by the following telegrams sent in January, 1916, to Count von Bernstorff:

Jan. 3 (Secret.) General staff desires energetic action in regard to proposed destruction of Canadian Pacific Railway at several points with a view to complete and protracted interruption of traffic. Captain Boehm, who is known on your side and shortly returning, has been given instructions. Inform the Military Attache and provide the necessary funds.

(Signed) ZIMMERMANN.

Jan. 26. For Military Attache. You can obtain particulars as to persons suitable for carrying on sabotage in the United States and Canada from the following persons: (1) Joseph McGarrity, Philadelphia, Penn. (2) John P. Keating, Michigan Ave., Chicago. (3) Jeremiah O'Leary, 16 Park Row, New York. One and two are absolutely reliable and discreet. No. 3 is reliable, but not always discreet. These persons were indicated by Sir Roger Casement. In the United States sabotage can be carried out on every kind of factory for supplying munitions of war. Railway embankments and bridges must not be touched. Embassy must in no circumstances be compromised. Similar precautions must be taken in regard to Irish pro-German propaganda.

(Signed)
REPRESENTATIVE OF GENERAL STAFF

The Start Of It

The earliest attempt to carry out these plans of the German General Staff was made by Horst von der Goltz, a German citizen who came to the United States from Mexico. In an affidavit he thus describes the origin and purposes of this project:

Shortly after my arrival at New York (from Mexico), I received a letter signed by Dr. Kraske, Vice-Consul at the German Consulate in New York, requesting me to attend at the consulate at a certain hour, in order that I might meet a gentleman who was interested in me. The letter was a mere matter of form, intended to inform me of the hour of a meeting proposed to me by Capt. von Papen.

Attending to this request I had at first some conversation with Capt. von Papen concerning events in Mexico, and afterwards was asked to give my opinion about a proposal made in a letter to the German Embassy, the writer of which asked for financial support, in order to carry out a scheme by which he wrote he would be able to make raids on towns situated on the Canadian coast of the Great Lakes.

The proposal being rejected on account of the Embassy receiving unfavorable information about the writer, I was first requested to give my assistance to a scheme of invasion intended to be put in execution by seizing some spot on the west coast of Canada with the assistance of German warships. Reservists from the United States were to be sent to another neutral country, where they were to be embarked. Such a step it was supposed would:

(1) Prevent the Canadian contingents then under training from sailing for Europe.
(2) Prevent Canada from supplying England with necessaries on account of their being needed in the country itself.
(3) Bring matters in the United States to a decision, the Government being forced either to supply both parties with arms and ammunition, or to prohibit the export of those articles altogether.

This scheme, proposed by Capt. von Papen and supported by Capt. Boy-Ed, was abandoned, objections having been made by Count Bernstorff.

Then two Irishmen, leaders of Irish associations, who both had fought during the Irish rebellion, proposed the wholesale blowing up of the canals connecting the Great Lakes, main railway junctions and grain elevators. It was alleged that by these means, as well as by wholesale distribution of proclamations intended to terrify the populace, combined with rumors of invasion judiciously circulated in the press, a panic would be created in Canada which would prevent the Dominion from giving any aid to England.

I was ordered to put this scheme in execution.

The Welland Canal

After these plans had been discussed at the German Consulate and at the German Club in New York City, it was decided that von der Goltz should attempt to blow up the Welland Canal, the grain elevators at Fort William, and, if possible, the Sault Ste. Marie locks and railroad bridges. Capt. von Papen supplied him at the German Club with the needed fuses, wire, and generators, and referred him for dynamite to Capt. Hans Tauscher, American agent for Krupp and other German makers of munitions. Von der Goltz told Tauscher about the plan to blow up the Welland Canal and received from him the following order for dynamite:

New York, Sept. 5, 1914.
E. I. du Pont de Nemours Powder Co.,
90 West Street, New York City.

Gentlemen:—Referring to my telephone conversation of yesterday, with your Mr. Clark, will you please deliver to bearer, Mr. Bridgman Taylor (a name assumed by von der Goltz), the three hundred (300) pounds sixty per cent. (60%) dynamite and send invoice to my above address for payment after delivery.

Yours very truly,
H. TAUSCHER.

The bill for dynamite which von der Goltz took with him to Buffalo and the receipts for money which he had received from Captain von Papen prior to his departure here follow:

E. I. du Pont de Nemours Powder Co.,
New York City, Sept. 11, 1914.
To H. Tauscher, 320 Broadway.
200 lbs. du Pont straight 60%.....$31.00

New York, 25 August.
I acknowledge the receipt of One Hundred Dollars.
HORST v. d. GOLTZ.

Imperial German Embassy,
Military Attache.
New York, Sept. 7, 1914.
I acknowledge the receipt of Six Hundred Dollars (expenses, of which two hundred dollars was in the form of a check on the Riggs National Bank at Washington).
H. V. D. GOLTZ.

The Plot Failed

Von der Goltz then went to Buffalo on the New York Central railroad with two suit cases containing about one hundred pounds of dynamite, but was unable to carry out his plans, because John Ryan, a Buffalo lawyer, did not give him the telegraphic instructions which von Papen had sent.

The conclusion of the expedition is marked by the following telegram sent by von Papen under an assumed name:

September 24, 1914.
John T. Ryan, Buffalo:
Please instruct Taylor cannot do anything more for him.
STEFFENS.

Captain von Papen promised to arrange with Ambassador von Bernstorff for von der Goltz' departure, and the following receipt shows what the arrangement was:

New York, October 1, 1914.
I acknowledge the receipt of \$150.00 with the obligation of using the amount for a voyage to Germany.
(Berlin General Staff.)
H. von der GOLTZ.

The following counterfoils in von Papen's checkbook show these records concerning expenditures for the expedition against the Welland Canal:

Sept. 1 (1914). Bridgman Taylor...\$200
Sept. 16. Taylor, Ryan, Buffalo..... 200
Sept. 22. Ryan, Buffalo 200
Oct. 14. "Fur Fritzen, Busse, Buffalo" 40

Receipts bearing the signature of von der Goltz show that in addition to the sums above mentioned he also received \$1,050.

With his confederates, Tauscher, von Papen, von Igel, Fritzen, Tuchendler, and Covani, he was indicted for conspiracy to set on foot a military enterprise against Great Britain. Von Papen and Boy-Ed, being attached to the German Embassy, were recalled by Germany on December 10, 1915, as the result of requests made by our Department of State. Von Igel returned to Germany with Ambassador Bernstorff in February, 1917, forfeiting his bond. Tauscher was acquitted, the jury appearing to believe his statement that he did not know the intended use of the dynamite which he assisted von der Goltz to procure. Fritzen has not been tried, having pleaded guilty to another indictment on which he was sentenced to eighteen months in prison, where he now is.

Another Attempt

Another attempt to blow up the Welland Canal was made in September, 1915, by Paul Koenig, head of the Bureau of Investigation of the Hamburg-American Line. This Bureau, increased in number after the war began, and operating from the offices of the steamship company at 45 Broadway, became the most dangerous sub-center of criminal intrigue maintained in America by the German Government. Among Koenig's papers is one entitled "History of the Bureau of Investigation," and under the year 1914 occurs this entry.

Aug. 22. German Government, with consent of Dr. Buenz, entrusted men with the handling of certain investigation. Military Attache von Papen called at my office later and explained the nature of the work expected. (Beginning of Bureau's services for Imperial German Government.

The measures adopted by Koenig to serve the German Government by blowing up the Welland Canal were thus described in a sworn statement made by George F. Fuchs, a member of the secret service division of the Hamburg-American Line, with whom Koenig had a conversation in Buffalo:

During the conversation he asked me if I would undertake work in Canada, to make observations and secure such information as I could regarding the Welland Canal, and more particularly calling my attention to the fact of observing how well the canal was patrolled by troops, and to ascertain how many locks there were on the canal and where they were situated. I agreed to perform this work and Koenig gave me the sum of $20 in cash to defray my expenses. . .

Koenig told me that the work I was to do along the canal in the way of making observations was very important and that it would be of great value to him. He also stated to me as near as I can remember that if the locks could be blown up it would cripple commerce and be a benefit to the Germans.

What They Paid Out

Fuchs made a written report to Koenig stating, "that with the use of explosives the canal could be crippled at a spot where the Chippewa River runs under the canal at Welland."

Koenig communicated with the German Embassy concerning the execution of this criminal plot, and frequently received money from both Boy-Ed and von Papen for various kinds of subterranean work. That he was in von Papen's employ is proved by the following entries in the latter's checkbook:

March 29, 1915. Paul Koenig (secret service, first bill), $509.11.
April 18, 1915. Paul Koenig (secret service bill), $90.94.
May 11, 1915. Paul Koenig (secret service), $66.71.
July 16, 1915. Paul Koenig (compensation for F. J. Busse), $150.00.
Aug. 4, 1915. Paul Koenig (5 bills secret service), $118.92.
Aug. 26, 1915. Paul Koenig (various cases in secret service), $247.24.
Oct. 11, 1915. Paul Koenig (4 bills secret service Sept.), $186.47.
Nov. 29, 1915. Paul Koenig (2 cases Reizl. Schumann), $77.24.

Koenig endeavored to protect himself and his fellow conspirators by depositing in the German Embassy at Washington toward the close of October, 1915, such papers as contained evidence of the many criminal plots in which they were engaged.

He did not succeed, however, in concealing all of the incriminating evidence of his plot to destroy the Welland Canal, and with an accomplice, Emil Leyendecker, was indicted on December 23, 1915, for "setting on foot a military enterprise" against Great Britain. The case has not been tried, Koeing being interned as an alien enemy.

Another military enterprise against Canada was undertaken by a prosperous citizen of the German Empire living in Detroit, Albert Kaltschmidt. He was a leader among the German-Americans of his city, had organized the "Deutscherbund" there and was its secretary.

The purposes of Kaltschmidt and his confederates are thus specified in their indictment by the Grand Jury:

(a) "To blow up the factory of the Peabody's Company, Limited, at Walkerville, Ontario, . . . engaged in manufacturing uniforms, clothing, and military supplies. . . .
(b) "To blow up . . . the building known as the Windsor Armories of the City of Windsor. . . . .
(c) "Two blow up and destroy other plants and buildings in said Dominion of Canada, which were used for the manufacture . . . of munitions of war, clothing, uniforms. . . . .
(d) "To blow up and destroy the great railroad bridges of the Canadian Pacific Railroad Co. at Nipigon. . . .
(e) "To employ and send into said Dominion of Canada spies to obtain military information. . . ."

The first grant of money which Kaltschmidt received to carry out these plans was $2,000, deposited on January 27, 1915, in a New York bank by Wolf von Igel. The original order of von Igel that this sum be telegraphed to Kaltschmidt and the latter's receipt for it were introduced as evidence during the trial.

With this working capital Kaltschmidt obtained the materials for his enterprise. In order that suspicion might not be aroused by the purchase of explosives in Detroit, he sent agents to Duluth, where they purchased the necessary dynamite, took it to Detroit, and began the construction of bombs. Two German reservists, Richard Herman and William M. Jarasch, were hired as confederates in Chicago, where the German consul-general, Baron Kurt von Reiswitz, was priv yto the plot. They laid plans under Kaltschmidt's direction to blow up the Detroit Screw Works, where shrapnel was being made, and the St. Clair tunnel which connects Canada with the United States, but failed in both attempts.

Jarosch was tending bar at the time he was hired by Kaltschmidt, and in his statement to an agent of the United States Department of Justice thus tells about other plans in view:

Jacobsen (an aid) told me that munition factories in Canada were to be blown up. Before I left for Detroit Jacobsen and I went to the Consulate. . . . We saw the Consul and he shook hands with me and wished me success. . . . .

Germany's diplomatic representatives were meanwhile supplying Kaltschmidt with money. Captain von Papen on March 27, 1915, drew a check on the Riggs National Bank of Washington for $1,000, payable to Wolf von Igel. Knauth, Nachod & Kuhne on the same day notified Kaltschmidt that von Igel had deposited $1,000 to his credit, and on March 30 Kaltschmidt drew a draft on this bank for that amount.

Charles F. Respa was concerned with operations in Canada, and at Kingston, Ontario, thus told American and Canadian officials what he was hired to do:

Q—How long had you been employed before he (Kaltschmidt) told you that he wanted you to blow up some of these factories?* A—About three weeks. . . .

Q—Did Kaltschmidt at the time speak of any particular place that he wanted you to blow up? A—The particular place was the Armory.

Q—Did he mention the Peabody Building at that time? A—Not particularly—he was more after the bridges and the armories and wanted those places blown up that made ammunition and military clothing. . . .

Q—The explosion at the armories was to be timed so that it would occur when the soldiers were asleep there? A—Yes, he did mention that he wanted to kill soldiers.

Q—Did he say that if the dynamite in the suitcase exploded it would kill the soldiers? A—I do not remember that he said so, but he must have known it.

Q—Did you take both grips? A—Yes.

Q—Where did you set the first grip? A—By the Peabody plant (blown up on June 20, 1915).

Q—Where did you put the other suitcase? A—Then I walked down the Walkerville road to the armories at Windsor and carried the suitcase. . . . .

Q—When you got to the armories did you know where to place It? A—I had my instructions.

Q—From Kaltschmidt? A—Yes. . . .

Q—Did you place this suitcase containing the dynamite bomb at the armory in a proper place to explode and do any damage? . . . . A—Yes.

Q—Was it properly connected so that the can would explode and atrike the dynamite? A—I fixed it so it would not.

Q—Did you deliberately fix this bomb that you took to the armories so that it would not explode? A—Yes.

Q—Why did you do that? A—I knew that the suitcase contained 30 sticks of dynamite and if exploded would blow up the armories and all the ammunition and would kill every man in it.

Respa, carelessly entering Canadian territory, was arrested and put on trial at Sandwich, Ontario. Kaltschmidt sent a friend to New York City to hire two witnesses to establish an alibi. This friend was instructed to call at the office of Captain von Papen, and upon giving the name Verner was to receive $1,000. Von Papen paid him the money, the two

*Respa and his accomplice were promised $200 each for their crime.

witnesses were brought to Detroit, but being entirely unsuitable for the desired purpose were sent home. The balance of the $1,000 was turned over to Kaltschmidt.

The last known financial transaction between Kaltschmidt and a member of the German Embassy is represented by the following letter:

H. F. Albert, 45 Broadway,
New York, Oct. 4, 1915.
Chase National Bank, 57 Broadway,
New York City:
Geneltmen:—Please deposit with Knauth, Nachod & Kuhne, New York, $25,000 (twenty-five thousand dollars) for account of Mr. Kaltschmidt, Detroit, and charge a like amount to my joint account with J. Bernstorff.
Yours very truly,
HEINRICH F. ALBERT.

Kaltschmidt was arrested in April, 1917, and his trial completed during December of the same year. The jury found him guilty on all charges in the indictment, and he was sentenced to four years in the Federal prison at Leavenworth, Kansas, and to pay a fine of $20,000. His sister, Ida K. Neef, was sentenced to three years in the Detroit House of Correction and to pay a fine of $15,000. Her husband, Fritz A. Neef, was sentenced to two years at Leavenworth and to pay a fine of $10,000. Two other accomplices received lighter sentences.

Another and more successful attack on the Grand Trunk Railway was made at Vanceboro, Maine, where it crosses the international bridge between the United States and Canada. Captain von Papen ordered Werner Horn, a German reserve lieutenant, to blow up the bridge and supplied him with $700. Horn was arrested immediately after an explosion which partly damaged the bridge, and at his trial in Boston, during June, 1917, made the following confession on the advice of his lawyers:

I admit and state that the facts set forth (in the indictments) as to the conveyance of explosives on certain passenger trains from New York to Boston and from Boston to Vanceboro, in the State of Maine, are true. I did, as therein alleged, receive an explosive . . . and conveyed the same from the City of New York to Boston . . . thence by common carrier from Boston . . . to Vanceboro, Maine. On or about the night of February 1, 1915, I took said explosive in a suitcase in which I was conveying it and carried the same across the bridge at Vanceboro to the Canadian side and there about 1.10 in the morning of Feb. 2, 1915, I caused said explosive to be exploded near or against the abutments of the bridge on the Canadian side, with intent to destroy the abutment and cripple the bridge so that the same could not be used for the passage of trains.

Horn was found guilty and sentenced to eighteen months at Atlanta penitentiary and the payment of a fine of $1,000.

The official representatives of Germany on the Pacific coast endeavored not only to sink ships, but also to carry out the command of the German General Staff that the Canadian Pacific Railroad be crippled. Franz Bopp, the German Consul-General in San Francisco, and his associates conspired to blow up the tunnels through which the railway passes under the Selkirk Mountains in British Columbia. They hired for this task J. H. van Koolbergen, the man who designed for them the bomb to be used on ships.

In the statement to the British authorities already quoted, van Koolbergen tells the story of this undertaking. After testifying that Lieutenant von Brincken summoned him by telephone, he continues:

Not knowing what he wanted I went to see him. . . . He was very pleasant and told me that he was an officer in the German army and at present working in the Secret Service of the German Empire under Mr. Franz Bopp, the Imperial German Consul. . . . .

I went to the Consulate and met Franz Bopp . . . and then saw von Brincken in another room. He asked me if I would do something for him in Canada . . . and I answered him, "Sure, I will do something, even blow up bridges, if there is money in it." . . . And he said, "You are the man; if that is so, you can make good money."

Von Brincken told me that they were willing to send me up to Canada to blow up one of the bridges on the Canadian Pacific Railroad or one of the tunnels. I asked him what was in it and he said he would talk it over with the German Consul Bopp. . . . .

I had accepted von Brincken's proposition to go to Canada and he offered me $500 to defray my expenses. . . . On different occasions in his room von Brincken showed me maps and information about Canada and pointed out to me where he wanted the act to be done. This was to be between Revelstoke and Vancouver on the Canadian Pacific Railroad, and I was to get $3,000 in case of a successful blowing up of a military train or bridge or tunnel.

After making a pretended attempt in collusion with Canadian railroad officials to blow up the tunnel, van Koolbergen returned to San Francisco and called on Mr. Bopp, who—

ordered the Vice Consul, Mr. von Schack, to pay me the additional $300 for traveling expenses. Mr. Bopp . . . ordered Mr. von Schack to get the money from the safe, and it was paid to me in greenbacks in the presence of Mr. von Schack, Mr. Bopp, and Mr. von Brincken. I agreed that I would be satisfied with $1,750 for my services in blowing up the tunnel, instead of the $3,000 as was first agreed upon and I was promised the money the next day. . . . .

I met von Brincken that (the next) afternoon and he brought $1,750 in greenbacks. Mr. Brincken had made arrangements before that with me that he should get a certain portion of the money from me; and I was paid $1,500, and $250 he got himself.

The information contained in the statements of Mr. van Koolbergen and L. J. Smith combined with a large amount of other evidence caused the Grand Jury to indict Bopp, von Schack, von Brincken, Crowley, and his secretary, Mrs. Margaret W. Cornell, for conspiracy to prepare and set on foot a military enterprise against Canada. All were found guilty and the men sentenced to serve two years in the penitentiary and to pay a fine of $10,000 each, with concurrent terms of one year in the county jail. Crowley and Mrs. Cornell, who received a lighter penalty, are now in prison; the others appealed to a higher court.

The men engaged by Consul-General Bopp at San Francisco attempted also to interrupt transportation of military supplies from the United States to Canada by crippling the Grand Trunk Railway. In his charge to the jury already quoted, the presiding justice said:

Smith says he went to Detroit and met Crowley; that they went to Port Huron to see about a tunnel running from Port Huron to Sarnia; Crowley told him that trains would come through about every six hours and that he should go down to where they fed the horses, and as they were being fed he could place a bomb in the cars and set the fuse long enough to explode the bomb in the car near the centre of the tunnel.

Nothing was accomplished here and the men returned to San Francisco.

QUIETENING WORN GEARS

By T. H.

The question of the suitability of ground cork as a quietening agent for noisy epicylic gearing recalls to mind several peculiar recipes that were in vogue a few years ago to suppress the noisy humming of more or less worn-out gears. The mixing of a liberal quantity of sawdust with the lubricant was one, whilst another was the charging of the box as full as possible with shavings of the sort used for packing fragile goods in, the usual lubricant being allowed to remain in.

The principle upon which these media were supposed to be based was that of acting as a cushion in between the teeth of the pinion and reducing the shock which set up the objectionable humming and vibration. Cork, being a much more elastic material than sawdust, ought to be more efficient for the purpose. Ground rubber might be even better but for the serious drawback that it would soon form a semi-fluid mass by reason of the action of the oil upon it, a fault which would not be found with cork, although any medium would ultimately lose its properties by being ground to a fine state of division.

There is some evidence that the plan of introducing sawdust, etc., into the gearbox is at least temporarily effective. It is not unknown to some of those who prepare second-hand cars for sale; and that even public service vehicles have managed to pass a silence test by this means.

It may be asked what, if any, objections are there to the plan. There does not seem to be any obvious reason why it should cause mechanical injury to the gearing providing that no solid matter is introduced, such as pieces of metal, which would jamb the gear, but there is at least one serious objection of another sort, viz., great waste of power by friction, due to the churning up of the semi-plastic mass by the gear teeth; the gear-box would, in fact, be acting as a continuous brake. There is also the difficulty of the proper lubrication of the gearshafts and bearings. The former would very likely make itself felt by causing stiffness in the operation of changing the gears.

Additional Power At Small Cost By Exhaust Steam Turbine

Exhaust Steam Turbines Connected to Line Shaft Through Reduction Gears With Beneficial Results in the Saving of Fuel and Boiler Capacity

MOTOR drive, the simplest solution to additional power problems, is often not available to mill owners, whose plants are driven by line shafts. Often, however, there is sufficient boiler capacity in his plant to do the work, if it is effectively applied, particularly where line shaft drive to a small number of machines is used. The installation of a turbine with speed-reducing gears is an ingenious solution to the problems.

A unique line shaft drive, consisting of a Westinghouse low pressure turbine and a Westinghouse double reduction gear has been recently installed in a large paper mill. There are two main line shafts to which the machines are belted. To one of the line shaft are belted two cutters, ten beaters and one Jordan; an identical equipment with the exception of the cutters is belted to the other shaft.

Only seven of the ten beaters, under ordinary running conditions are in operation at one time, and these with one Jordan require about 600 horse power, an additional 20 horse power for the rag cutters.

Heretofore, these two line-shafts were each driven by a non-condensing reciprocating engine. However, one of these engines was wrecked and so necessitated the obtaining of a drive to replace it, at the least ultimate expense.

It is interesting to note the considerations entering into the final selection of the new drive. These conditions were somewhat as follows: two 100 horse power non-condensing engines turned the rolls and gave practically all the exhaust steam necessary for feed water heating, so that all the exhaust steam from the 700-horse-power non-condensing Corliss engine driving one of the line shafts would have to be discharged to the atmosphere, unless some means were provided for abstracting the energy still available in it. A low pressure turbine was the prime mover, without a doubt, but it would have been of little use, on account of its high speed, had there not been a reduction gear to receive the power generated to deliver it to the line shaft at low speed.

Other types of drive were considered, but each had inherent characteristics which disqualified it. For instance, a duplication of the old reciprocating engine was stepping back into the old rut, with the inevitable wasting of exhaust steam. A condensing engine would have been expensive, and no material improvement. Again, an electric motor, while comparatively cheap to instal, would have been much more expensive, when the electric power bill was added to the cost of energy lost in wasted exhaust steam. And finally, it was still more expensive to instal a turbine generator and an individual electric drive, because the existing equipment was of an entirely different character. However, in a new plant, where all equipment is being installed for the first time, the individual electric drive is by far the best, for reasons too well known to need discussion here.

A few approximate figures show more clearly the fitness of low-pressure turbine for this application. The exhaust steam from the 700-horse-power Corliss engine was more than sufficient to give 600 horse power in the low pressure turbine. The engine takes steam at 150 pounds pressure, and exhausts into an oil separator at a back pressure, depending on the load, from 0 to 4 or 6 pounds, which is approximately the pressure of admission to the low pressure turbine. The steam is then expanded in the turbine down to a vacuum corresponding to 27½ inches of mercury referred to a 30-inch barometer, the vacuum being maintained by a Westinghouse-Le Blanc low level jet condenser and air pump. The pumps are centrifugal and are driven by a small turbine through a reduction gear. They take their water from a nearby creek and discharge it from the condenser into a reservoir at an elevation of 45 feet, which water is used in the manufacturing processes. The small turbine runs non-condensing, and its exhaust steam goes to the feed water heater, so that only a part of the heat energy in the steam used by it can be charged to the turbine, and even that cannot be charged against the main turbine for it is used to do work in elevating the discharge water from the condenser to the reservoir and should be charged against the total cost of manufacturing. In brief, it may be said that this paper company actually gets 600 horse power without paying a cent for steam, and that it is using just one-half the steam they formerly used with two reciprocating engines to obtain the same power.

While this particular mill was not en-

VIEW OF TURBINE AND DOUBLE REDUCTION GEARING.

larged, it is evident that with a given amount of exhaust steam, either from non-condensing engines or condensing engines run non-condensing, a large increase of power is made available by the installation of a low pressure turbine. Further evidence of this possibility for expansion is the fact that in this paper mill when the two line shafts were driven by non-condensing reciprocating engines, a battery of 13 boilers was required, whereas now only eight boilers are required for the maximum load.

So far this has been a discussion of the application of a low pressure turbine, but the means of transmitting its high speed power to a slow speed line shaft is fully interesting and as important. The change in speed is made by means of two reduction gears because the first cost of a single gear and pinion of ratio 36 to 1 would be prohibitive, and the gear would be very large and unwieldy. The first speed reduction, 3,600 r.p.m., to 720 r.p.m., is made with a fixed bearing type of reduction gear, the gear shaft of which is direct connected to the pinion shaft of the second gear which reduces the speed from 720 to 103 r.p.m.

This larger reduction gear is of the flexible pinion frame type, better known as the Westinghouse I-beam type. It is this I-beam feature which makes the application of the geared drive possible.

In this the pinion is supported on three bearings in a frame, as shown in Fig. 3. This frame is supported under the middle bearing on an I-beam at right angles to the pinion axle. The flexibility of the web of this I-beam support allows the pinion to tip slightly and to let the teeth of the pinion line up with those of the gear. This lining-up is entirely automatic and instantaneous in operation, so that no mechanical complications are encountered, and no adjustments from the outside of the gear case are necessary at any time.

Both reduction gears are lubricated by sprays of oil directed upon the teeth just before the mesh. The pressure is maintained by a pump geared to the gear shaft, as shown in Fig. 11. This pump also supplies oil under pressure to all the bearings in the two reduction gears. For starting, a hand pump is provided which insures a plentiful supply of oil on the bearings and teeth.

It may be asked why a fixed bearing type of reduction gear was used in one case and an I-beam in the other. It was a question of tooth pressure which determined the design. Take for instance a pinion transmitting 600 horse power at 3,600 r.p.m., which was the case of the first reduction gear in the particular installation under discussion. If the same pinion were to turn at 720 r.p.m. and with the same tooth pressure (i.e., pounds pressure per inch) of tooth face it would be capable of transmitting one-fifth of 600 horse power, or 120 horse power only. It follows, then, that the second gear would have been made five times as large as the first if the same type had been used, and for the transmission of the same amount of power. Such reduction gear would have been large and bulky. It would also have been costly, because cost is a function of size.

In order, then, to make a reduction gear which would be within reasonable limits as to size, and at the same time marketable, the allowable tooth pressure had to be increased, or in other words the factor of safety included in the allowable stress in ordering fixed bearing design had to be lowered. But if this were done, some other safety factor would have to be incorporated to insure reliability of operation, otherwise a slight misalignment of the teeth and uneven distribution of tooth pressure would have resulted in a failure of the gear.

This safety factor was found in the Westinghouse I-beam support for the pinion which corrects any misalignment and uneven pressure distribution which might otherwise exist. Misalignment might have been due to temperature changes, slight but unavoidable inaccuracies in workmanship, or distortion of the bearing supports in the housing, due to varying loads or changes in foundations, and if not corrected would have caused the total tooth pressure to be concentrated at one part of the tooth which would have overstressed that part of the tooth and have caused it to fail.

In the case of the reduction gear with fixed bearing support for the pinion, misalignment, although practically prevented by good workmanship, will not have disastrous results if it should exist, because of the high factor of safety used in the tooth design. In other words, localization of total tooth pressure would not stress the metal beyond a safe limit.

The self-aligning feature, the forced lubrication, the rugged construction of the parts, and the workmanship on these reduction gears make them a very efficient and reliable means of transmitting power. The actual efficiency of the two gears together is 97 per cent., showing that only 3 per cent. of the total power transmitted is lost in them. This energy is dissipated in the form of heat, and is taken up by the oil, which in turn is cooled by a water cooling system. As to reliability, in the paper mill under discussion the double reduction gear has run 24 hours per day, six days per week, under maximum load, and it has never been shut down on account of trouble with the gears.

THE THREE PIONION BEARINGS ARE SUPPORTED ON A FRAME WHICH IN TURN IS SUPPORTED ON TWO SUPPORTS OF "I" BEAM SECTION.

CEMENTS FOR PIPE JOINTS

By M. E.

Cement for making screw joints in pipes steam-tight may be made from graphite and heavy cylinder oil. Just enough oil is mixed with the graphite to form a thick paste.

A good cement for both water and steam pipes has this composition: Whiting, 4 pounds; fine yellow ochre, 10 pounds; ground litharge, 4 pounds, and one-half pound of hemp cut into fine particles. These ingredients are mixed thoroughly with linseed oil to form a paste, which is applied on the threads of the pipes, etc.

For ammonia piping, a cement made of litharge and glycerine is used. Sufficient glycerine is added to the litharge to form a putty. Only enough of this cement should be mixed to serve immediate needs, as it sets quickly. After having once set, it should not be disturbed.

574. Galvanized sheets.—A Liverpool firm would like quotations on 100 tons of galvanized sheets, assorted, 6-foot to 10-foot lengths by 8/3 by 24 G., in bundles, felted for direct shipment to Callao, South America.

Tracing the Development and Use of Semisteel

Great Use Was Made of it in France to Secure Great Amount of Munitions in 1917—Greatly Used in Auto and Truck Trade—McLain Has Much to do With it

THE progress shown and recorded in the advancement and uses of semi-steel since 1903, when the last Foundrymen's Convention was held in Milwaukee, is remarkable. It is undoubtedly true that the history of the successes of other industries is made with many obstacles and semi-steel was no exception.

For fifty years or more, foundrymen had added steel to iron in the ladle—while comparatively few melted slight amounts of steel in the cupola. According to an English authority a patent was issued on the manufacture of a new cast or wrought metal containing steel more than half a century ago, and this discovery then was acclaimed by British foundrymen generally as semi-steel. To the late Major McDowell of Chicago must be attributed the honor of placing the semi-steel process on a scientific basis and upon his great work as a foundation the accomplishments of to-day have been made possible.

But up to 1902 or 1903 no record was found where large percentages of steel was used in castings of *light* section. It remained for David McLain of Milwaukee to perfect experiments along this line and give to the world a metal that would be put at the top of the list of cupola or air furnace metals, and he called it semi-steel.

Until the past five years semi-steel has been ridiculed and classed as a misnomer by even some of the foremost metallurgists in the field, but to-day our Government is specifying semi-steel projectiles and shells by the million.

Just about a year ago it was claimed that semi-steel shells saved France. One of the most striking cases of efficient substitution is illustrated in the French semi-steel shells replacing steel. To further show the characteristic of the French genius in meeting spontaneously an emergency, that with a sudden shortage of steel and with the greater part of their blast furnaces in enemy hands, little iron foundries were established everywhere—almost literally over night—and the necessary output of shells thus maintained.

The best proof of its value and its existence as a distinct product is the fact that the bulk of the automobile and motor truck cylinders used in this country to-day are made from semi-steel, and it is the only metal that has been able to drive from the American market the wonderful cylinder castings shipped into this country in the past from France at fabulous prices. But the use of semi-steel not only is limited to comparatively light work. Many foundries have established a reputation for the manufacture, under high-sounding trade names, of vacuum cylinders and ammonia steel castings which, upon investigation, are found to be semi-steel. The foregoing are only a few instances of the remarkable accomplishments of semi-steel. They could be multiplied indefinitely.

The Beginning of a New Era in Metallurgy

In 1899, the Christensen Engineering Company (now the National Brake and Electric Company, Milwaukee) built their first foundry. Gray iron, steel and brass castings were made in this plant and David McLain was the foundry superintendent for five and one-half years.

Certain parts of the air brakes were only 5/16 inch thick and tested to 200 pounds air pressure, although other engineers allowed one inch. Founders everywhere who made these castings experienced excessive losses, making it difficult for this firm to fill their orders. This was the condition when Mr. McLain was engaged. Much of the history of his experiments have been told in these columns before, so we will not dwell on this part except to emphasize the fact that he was successful in demonstrating that these castings could be made by adding 25 to 40 per cent. steel.

Mr. McLain's friends insisted that he patent his formulas, but he believed in spreading his knowledge of this metal to the foundry trade gratuitously. At that time he was anxious to enlighten foundrymen everywhere on the merits of this wonderful metal, and later, through the kindness of Mr. R. P. Tell, general manager of the National Brake & Electric Company, copies of Mr. McLain's first paper on semi-steel were typewritten and sent to foundrymen everywhere.

It was proven by later demonstration that semi-steel is a purer and stronger metal than gray iron—stands the test for Government specifications for projectiles (32,000 pounds tensile)—and when used with 30 to 50 per cent. steel scrap will run as high as 40,000 and 45,000 pounds.

Prominent technical and practical foundrymen, some of whom no doubt will attend this meeting, maintained that steel reduced carbon, that it was not a good thing to use as it caused "hard spots"—that "a higher melting temperature was necessary"—"more coke required to melt it," etc. Even to-day, Mr. McLain's claim that steel melts first puzzles some chemists, metallurgists and others, who evidently do not take into consideration that steel has a great affinity for the elements and absorbs a large quantity of carbon from the fuel.
